Aafjes-van Doorn, Katie; Lilliengren, Peter; Cooper, Angela; Macdonald, James; Falkenström, Fredrik	2017	Patients' affective processes within initial experiential dynamic therapy sessions	Psychotherapy	54	2	175-183	<p>Research has indicated that patients' in-session experience of previously avoided affects may be important for effective psychotherapy. The aim of this study was to investigate patients' in-session levels of affect experiencing in relation to their corresponding levels of insight, motivation, and inhibitory affects in initial Experiential Dynamic Therapy (EDT) sessions. Four hundred sixty-six 10-min video segments from 31 initial sessions were rated using the Achievement of Therapeutic Objectives Scale. A series of multilevel growth models, controlling for between-therapist variability, were estimated to predict patients' adaptive affect experiencing (Activating Affects) across session segments. In line with our expectations, higher within-person levels of Insight and Motivation related to higher levels of Activating Affects per segment. Contrary to expectations, however, lower levels of Inhibition were not associated with higher levels of Activating Affects. Further, using a time-lagged model, we did not find that the levels of Insight, Motivation, or Inhibition during one session segment predicted Activating Affects in the next, possibly indicating that 10-min segments may be suboptimal for testing temporal relationships in affective processes. Our results suggest that, to intensify patients' immediate affect experiencing in initial EDT sessions, therapists should focus on increasing insight into defensive patterns and, in particular, motivation to give them up. Future research should examine the impact of</p>

							specific inhibitory affects more closely, as well as between-therapist variability in patients' in-session adaptive affect experiencing. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Aafjes-van Doorn, Katie; Luo, Xiaochen; Kealy, David; McCollum, James; Silberschatz, George	2023	Interpersonal guilt and the working alliance in psychotherapy: The moderating role of childhood experience	Clinical psychology & psychotherapy	30	1	141-151	Interpersonal guilt often encompasses pathogenic beliefs that imply omnipotent responsibility for others and concerns about abandoning, humiliating or threatening others. This study sought to examine how interpersonal guilt may influence patients' and therapists' ratings of early working alliance and the potential moderating effect of perceived adverse parenting in childhood. Ninety-five patients and their 19 therapists in an outpatient psychotherapy clinic rated their early working alliance after the first and the fifth session in treatment. We conducted separate moderation analyses for patient and therapist-reported working alliance and controlled for psychological distress at baseline. Results suggest that perceived adverse parenting in childhood significantly moderated the effect of interpersonal guilt on the working alliance in such a way that for patients reporting very low levels of perceived adverse experiences, the interpersonal guilt beliefs had a positive effect on working alliance, whereas for those with very high levels of perceived adverse experiences, interpersonal guilt had a negative effect on working alliance. This same pattern of moderation was found for patient- and therapist-reported working alliance at session 1 and therapist-reported working alliance at session 5. Thus, although the effect of interpersonal guilt on the working alliance depends somewhat on the perspective of the working alliance rating (patient or therapist), it mainly depends on developmental experiences of the patient.

Aalbers, George; Engels, Tiarah; Haslbeck, Jonas M. B.; Borsboom, Denny; Arntz, Arnoud	2021	The network structure of schema modes	Clinical psychology & psychotherapy	28	5	1065– 1078	<p>A fundamental question in psychotherapy is whether interventions should target client problems (i.e., problem-focused approaches) or client strengths (i.e., strength-focused approaches). In this study, we first propose to address this question from a network perspective on schema modes (i.e., healthy or dysfunctional patterns of co-occurring emotions, cognitions, and behaviours). From this perspective, schema modes mutually influence each other (e.g., healthy modes reduce dysfunctional modes). Recent evidence suggests that changes in modes that are strongly associated to other modes (i.e., central modes) could be associated with greater treatment effects. We therefore suggest research should investigate the relative centrality of healthy and dysfunctional modes. To make an exploratory start, we investigated the cross-sectional network structure of schema modes in a clinical (comprising individuals diagnosed with paranoid, narcissistic, histrionic, and Cluster C personality disorders) and non-clinical sample. Results showed that, in both samples, the Healthy Adult was significantly less central than several dysfunctional modes (e.g., Undisciplined Child and Abandoned and Abused Child). Although our study cannot draw causal conclusions, this finding could suggest that weakening dysfunctional modes (compared to strengthening the Healthy Adult) might be more effective in decreasing other dysfunctional modes. Our study further indicates that several schema modes are negatively associated, which could suggest that decreasing one might increase another. Finally, the Healthy Adult was among the modes that most strongly discriminated between clinical and non-clinical individuals. Longitudinal and experimental research into the network structure of schema modes is</p>
---	------	---	---	----	---	---------------	---

							required to further clarify the relative influence of schema modes.
Abargil, Maayan; Tishby, Orya	2022	Countertransference awareness and treatment outcome		69	5		Countertransference (CT) is considered a central component in the therapy process. Research has shown that CT management does not reduce the number of CT manifestations in therapy, but it leads to better therapy outcomes. In this study, we examined therapists' awareness of their CT using a structured interview. Our hypotheses were (a) treatments in which therapists were more aware of their CT would have a better outcome and (b) different definitions of CT would be related to different therapy outcomes. Twenty-nine patients were treated by 19 therapists in 16 sessions of short-term psychodynamic therapy. We used the core conflictual relationship theme to measure CT, a special interview was developed to study CT awareness. Results show that awareness of CT defined as the relationship with the patient moderated 10 outcome measures and awareness of CT defined as the relationship with the patient that repeats therapist conflicts with significant others moderated three outcome measures We present examples from dyads in this study and discuss how awareness can help the therapist talk to and handle patient challenges. Abargil, Maayan; Wiseman, Hadas; Yonatan-Leus, Refael; Tishby, Orya	2023	Changes in clients' relational patterns with parents and therapist during psychodynamic psychotherapy: Their	Journal of clinical psychology	79	10	2422–2438	<p>OBJECTIVE</p> <p>The study aimed to explore how changes in clients' relational patterns during psychodynamic psychotherapy relate to treatment outcomes and therapy effectiveness.</p> <p>METHOD</p> <p>Seventy clients receiving psychodynamic psychotherapy in a university counseling center were interviewed three times and filled out the OQ-45 questionnaire five times during therapy. We used the Core Conflictual</p>

		association and relation to treatment outcome				<p>Relationship Theme (CCRT) to study clients' relational patterns. Mixed models were used to assess the interaction between clients' CCRT intensity toward their parents and toward their therapists, treatment effectiveness, and treatment outcome.</p> <p>RESULTS</p> <p>First, we found that clients' relational patterns with their parents correlated with relational patterns with their therapists across several time points in therapy. Then, we found significant interactions, indicating that treatment effectiveness moderates the relationship between clients' CCRT intensity and treatment outcomes.</p> <p>CONCLUSIONS</p> <p>The findings suggest that the transference phenomenon is related to therapy outcomes differently in effective and less-effective therapies, depending on the transference intensity. Further research is needed to expand knowledge about the intensity of transference and its possible impact on treatment choice and management.</p>
Abayomi, Olukayode; Chibuzor, Moriam T.; Okusanya, Babasola O.; Esu, Ekperonne; Odey, Edward; Meremikwu, Martin M.	2017	Supportive psychotherapy or client education alongside surgical procedures to correct complications of female genital mutilation: A systematic review	International journal of gynaecology and obstetrics: the official organ of the International Federation of Gynaecology and Obstetrics	136 Supplement 1	51–55	<p>BACKGROUND</p> <p>Supportive psychotherapy, in individual or group settings, may help improve surgical outcomes for women and girls living with female genital mutilation (FGM).</p> <p>OBJECTIVES</p> <p>To assess whether supportive psychotherapy given alongside surgical procedures to correct complications of FGM improves clinical outcomes.</p> <p>SEARCH STRATEGY</p> <p>We searched major databases including CENTRAL, Medline, African Index Medicus, SCOPUS, PsycINFO, and others. There were no language restrictions. We checked the reference lists of retrieved studies for additional reports of relevant studies.</p>

							<p>SELECTION CRITERIA We included studies of girls and women living with any type of FGM who received supportive psychotherapy or client education sessions alongside any surgical procedure to correct health complications from FGM.</p> <p>DATA COLLECTION AND ANALYSIS Two team members independently screened studies for eligibility.</p> <p>MAIN RESULTS There were no eligible studies identified.</p> <p>CONCLUSIONS There is no direct evidence for the benefits or harms of supportive psychotherapy alongside surgical procedures for women and girls living with FGM. Research evidence is urgently needed to guide clinical practice.</p> <p>PROSPERO REGISTRATION 42015024639.</p>
Abbass, Allan A.; Town, Joel M.	2021	Alliance rupture-repair processes in intensive short-term dynamic psychotherapy: Working with resistance	Journal of clinical psychology	77	2	398–413	<p>Intensive short-term dynamic psychotherapy (ISTDP) was developed to manage treatment impasses preventing the experiencing of feelings related to childhood attachment interruptions, such as parental loss. According to ISTDP theory, certain categories of patients will exhibit habitual patterns of responding within the treatment relationship (called defenses) to certain anxiety-provoking thoughts and feelings. Such defensive behaviors interrupt awareness of one's own feelings, self-directed compassion and engagement in close human attachments, including the bond with the therapist. Rupture-repair sequences in ISTDP are primarily considered in the context of a patient's defenses and the responses a therapist has to these defenses. By understanding and clarifying these defenses, this risk of subsequent misalliance, that is negative shifts or ruptures</p>

							in the alliance, are minimized. In this paper we summarize ISTDP theory and technique through the use of clinical vignettes to illustrate defense management as a rupture-repair equivalent in ISTDP.
Abbott, Caroline H.; Zisk, Abigail; Bounoua, Nadia; Diamond, Guy S.; Kobak, Roger	2019	Predicting Patterns of Treatment Response and Outcome for Adolescents Who Are Suicidal and Depressed	Journal of the American Academy of Child and Adolescent Psychiatry	58	9	897-906	<p>OBJECTIVE: Although several treatments have been shown to be effective in treatment of youth suicidal thoughts and behaviors (STBs), there is a pressing need to account for the substantial variation in adolescents' response to and outcomes from these treatments.</p> <p>METHOD: Secondary analyses of data from a 16-week randomized trial of Attachment-Based Family Therapy (ABFT) and Family-Enhanced NonDirective Supportive Therapy (FE-NST) identified distinct classes of adolescents' treatment response. Established risk factors for STBs, along with treatment condition and sociodemographic variables, were then tested as predictors of class membership.</p> <p>RESULTS: Three patterns of adolescents' treatment response and outcome were identified: a) nonresponders (15.8%), b) good responders (57.5%), and c) partial responders (26.7%). After controlling for initial symptom severity, nonresponders were more likely to have higher levels of nonsuicidal self-injury and pessimism and were more likely to meet diagnostic criteria for major depressive disorder (MDD) than good or partial responders. Partial responders were more likely than good responders to meet criteria for MDD and to have higher perceived burdensomeness.</p> <p>CONCLUSION: Although most adolescents showed significant symptom reductions with both treatments, adolescents with higher pretreatment levels of pessimism, MDD, nonsuicidal self-injury, and perceived burdensomeness were less likely to show an optimal pattern of treatment benefit. The findings point to</p>

							heterogeneity in treatment response that may require adapting treatments for adolescents with these pretreatment profiles. CLINICAL TRIAL REGISTRATION INFORMATION: Attachment-Based Family Therapy for Suicidal Adolescents; http://clinicaltrials.gov ; NCT01537419.
Abou El-Magd, Rabab M.; Obuobi-Donkor, Gloria; Adu, Medard K.; Lachowski, Christopher; Duddumpudi, Surekha; Lawal, Mobolaji A.; Sapara, Adegboyega O.; Achor, Michael; Kouzehgaran, Maryam; Hegde, Roshan; Chew, Corina; Mach, Mike; Daubert, Shelley; Urichuk, Liana; Snaterse, Mark; Suhood, Shireen; Li, Daniel; Greenshaw, Andrew; Agyapong,	2020	Repetitive Transcranial Magnetic Stimulation With and Without Internet-Delivered Cognitive-Behavioral Therapy for the Treatment of Resistant Depression: Protocol for Patient-Centered Randomized Controlled Pilot Trial	JMIR research protocols	9	10	e18843	BACKGROUND: Major depression is a severe, disabling, and potentially lethal clinical disorder. Only about half of patients respond to an initial course of antidepressant pharmacotherapy. At least 15% of all patients with major depressive disorder (MDD) remain refractory to any treatment intervention. By the time that a patient has experienced 3 definitive treatment failures, the likelihood of achieving remission with the fourth treatment option offered is below 10%. Repetitive transcranial magnetic stimulation (rTMS) is considered a treatment option for patients with MDD who are refractory to antidepressant treatment. It is not currently known if the addition of internet-delivered cognitive-behavioral therapy (iCBT) enhances patients' responses to rTMS treatments. OBJECTIVE: This study will evaluate the initial comparative clinical effectiveness of rTMS with and without iCBT as an innovative patient-centered intervention for the treatment of participants diagnosed with treatment-resistant depression (TRD). METHODS: This study is a prospective, two-arm randomized controlled trial. In total, 100 participants diagnosed with resistant depression at a psychiatric care clinic in Edmonton, Alberta, Canada, will be randomized to one of two conditions: (1) enrolment in rTMS sessions alone and (2) enrolment in the rTMS sessions plus iCBT. Participants in each group will complete evaluation measures (eg, recovery, general symptomatology, and functional

Vincent Israel Opoku							<p>outcomes) at baseline, 1 month, 3 months, and 6 months. The primary outcome measure will be the mean change to scores on the Hamilton Depression Rating Scale. Patient service utilization data and clinician-rated measures will also be used to gauge patient progress. Patient data will be analyzed with descriptive statistics, repeated measures, and correlational analyses.</p> <p>RESULTS: We expect the results of the study to be available in 24 months. We hypothesize that participants enrolled in the study who receive rTMS plus iCBT will achieve superior outcomes in comparison to participants who receive rTMS alone. CONCLUSIONS: The concomitant application of psychotherapy with rTMS has not been investigated previously. We hope that this project will provide us with a concrete base of data to evaluate the practical application and efficacy of using a novel combination of these two treatment modalities (rTMS plus iCBT). TRIAL REGISTRATION: ClinicalTrials.gov NCT0423965; https://clinicaltrials.gov/ct2/show/NCT04239651. INTERNATIONAL REGISTERED REPORT IDENTIFIER (IRRID): PRR1-10.2196/18843.</p>
Acevedo, Nicola; Castle, David; Groves, Clare; Bosanac, Peter; Mosley, Philip E.; Rossell, Susan	2022	Clinical recommendations for the care of people with treatment-refractory obsessive-compulsive disorder when undergoing	The Australian and New Zealand journal of psychiatry	56	10	1219–1225	<p>Deep brain stimulation is an emerging therapy for treatment-refractory obsessive-compulsive disorder patients. Yet, accessibility is limited, treatment protocols are heterogeneous and there is no guideline or consensus on the best practices. Here, we combine evidence from scientific investigations, expert opinions and our clinical expertise to propose several clinical recommendations from the pre-operative, surgical and post-operative phases of deep brain stimulation care for treatment-refractory obsessive-compulsive disorder patients. A person-centered and biopsychosocial approach is</p>

		deep brain stimulation					adopted. Briefly, we discuss clinical characteristics associated with response, the use of improved educational materials, an evaluative consent process, comprehensive programming by an expert clinician, a more global assessment of treatment efficacy, multi-disciplinary adjunct psychotherapy and the importance of peer support programs. Furthermore, where gaps are identified, future research suggestions are made, including connectome surgical targeting, scientific evaluation of hardware models and health economic data. In addition, we encourage collaborative groups of data and knowledge sharing by way of a clinical registry and a peer group of programming clinicians. We aim to commence a discussion on the determinants of deep brain stimulation efficacy for treatment-refractory obsessive-compulsive disorder patients, a rare and severe patient group, and contribute to more standardized and evidence-based practices.
Aceves-Martins, Magaly; Quinton, Richard; Brazzelli, Miriam; Cruickshank, Moira; Manson, Paul; Hudson, Jemma; Oliver, Nick; Hernandez, Rodolfo; Aucott, Lorna; Wu, Frederick;	2022	Identifying the outcomes important to men with hypogonadism: A qualitative evidence synthesis	Andrology	10	4	625–641	OBJECTIVE: Men with male hypogonadism (MH) experience sexual dysfunction, which improves with testosterone replacement therapy (TRT). However, randomised controlled trials provide little consensus on functional and behavioural symptoms in hypogonadal men; these are often better captured by qualitative information from individual patient experience. METHODS: We systematically searched major electronic databases to identify qualitative data from men with hypogonadism, with or without TRT. Two independent authors performed the selection, extraction, and thematic analysis of data. Quality of eligible studies was assessed using the Critical Appraisals Skills Programme and Grading of Recommendations Assessment, Development and Evaluation-Confidence in the Evidence

<p>Dhillon, Waljit S.; Bhattacharya, Siladitya; Gillies, Katie; Jayasena, Channa N.</p>						<p>from Reviews of Qualitative research tools. RESULTS: We analysed data from five studies published in nine reports that assessed a total of 284 participants. Published data were only available within North America, with no ethnic minority or other underserved groups included. In addition to sexual dysfunction, men with MH experienced adverse changes in physical strength, perceptions of masculinity, cognitive function, and quality of life. The experience of MH appeared dependent on the source(s) of educational material. DISCUSSION: We propose a patient-centred approach to clinician interactions rather than focusing on discreet MH symptoms. Current evidence about the experience of MH is limited to North America and predominantly white ethnicity, which may not be broadly applicable to other geographic regions. Broadening our understanding of the MH experience may improve the targeting of information to patients. In addition, a multidisciplinary approach may better address symptoms neither attributable to MH nor alleviated by TRT.</p>
<p>Adames, Hector Y.; Chavez-Dueñas, Nayeli Y.; Sharma, Shweta; La Roche, Martin J.</p>		<p>Intersectionality in psychotherapy: The experiences of an AfroLatinx queer immigrant</p>	<p>Psychotherapy</p>	<p>55</p>	<p>1</p>	<p>Culturally responsive and racially conscious psychotherapeutic work requires that therapists recognize the ways clients are impacted by their multiple marginalized identities and by systems of oppression (e.g., racism, ethnocentrism, sexism, heterosexism, and nativism). Attending exclusively to clients' marginalized identities (i.e., weak intersectionality) may drive therapists to only focus on internal, subjective, and emotional experiences, hence, missing the opportunity to consider and address how multiple sociostructural dimensions (i.e., strong intersectionality) may be impacting the client's presenting problems. Alternatively, focusing solely on the impact of sociostructural</p>

							dimensions on the lives of clients may miss the more nuanced and variable individual personal experiences. In this article, we highlight the challenge of maintaining a culturally responsive and racially conscious stance when considering multiple marginalized identities, overlapping systemic inequities, and how both affect clients' lives and experiences. The case of an AfroLatinx queer immigrant is presented to illustrate some of the challenges and opportunities while simultaneously considering (a) the client's multiple marginalized identities, (b) the way clients are impacted by systemic oppression, and (c) integrating the client's personal experiences and narratives in psychotherapy. Adams, Thomas G.; Cisler, Josh M.; Kelmendi, Benjamin; George, Jamilah R.; Kichuk, Stephen A.; Averill, Christopher L.; Anticevic, Alan; Abdallah, Chadi G.; Pittenger, Christopher	2022	Transcranial direct current stimulation targeting the medial prefrontal cortex modulates functional connectivity and enhances safety learning in obsessive-compulsive disorder: Results from two pilot studies	Depression and anxiety	39	1	37-48	<p>BACKGROUND</p> <p>Exposed-based psychotherapy is a mainstay of treatment for obsessive-compulsive disorder (OCD) and anxious psychopathology. The medial prefrontal cortex (mPFC) and the default mode network (DMN), which is anchored by the mPFC, promote safety learning. Neuromodulation targeting the mPFC might augment therapeutic safety learning and enhance response to exposure-based therapies.</p> <p>METHODS</p> <p>To characterize the effects of mPFC neuromodulation on functional connectivity, 17 community volunteers completed resting-state functional magnetic resonance imaging scans before and after 20 min of frontopolar anodal multifocal transcranial direct current stimulation (tDCS). To examine the effects of tDCS on therapeutic safety learning, 24 patients with OCD completed a pilot randomized clinical trial; they were randomly assigned (double-blind, 50:50) to receive active or sham</p>

						<p>frontopolar tDCS before completing an in vivo exposure and response prevention (ERP) challenge. Changes in subjective emotional distress during the ERP challenge were used to index therapeutic safety learning.</p> <p>RESULTS</p> <p>In community volunteers, frontal pole functional connectivity with the middle and superior frontal gyri increased, while connectivity with the anterior insula and basal ganglia decreased ($ps < .001$, corrected) after tDCS; functional connectivity between DMN and salience network also decreased after tDCS ($ps < .001$, corrected). OCD patients who received active tDCS exhibited more rapid therapeutic safety learning ($ps < .05$) during the ERP challenge than patients who received sham tDCS.</p> <p>CONCLUSIONS</p> <p>Frontopolar tDCS may modulate mPFC and DMN functional connectivity and can accelerate therapeutic safety learning. Though limited by small samples, these findings motivate further exploration of the effects of frontopolar tDCS on neural and behavioral targets associated with exposure-based psychotherapies.</p>	
Adarsh, Himani; Sahoo, Swapnajeet; Sachdeva, Diksha; Tripathy, Satyaswarup; Kumar, Rajesh	2022	Post-traumatic stress disorder following traumatic limb amputation in an 8 year-old female child and its management through play therapy	Asian journal of psychiatry	78		103304	<p>Posttraumatic mental health issues following traumatic limb amputations in children have been commonly reported worldwide. Traumatic limb amputations are catastrophic injuries/events and often have various long term psycho-social impacts on children. We report a case of 8 year-old female child presenting with symptoms of post-traumatic stress disorder (PTSD) following a traumatic amputation of right hand. A non-directive approach in play therapy was used for management of her symptoms. At 12 months follow up, the child is doing well with no impairment in her overall functioning.</p>

Adelina, Nadia; Chan, Christian S.; Takano, Keisuke; Yu, Placida Hoi Man; Wong, Patrina Hei Tung; Barry, Tom J.	2023	The Stories We Tell Influence the Support We Receive: Examining the Reception of Support-Seeking Messages on Reddit	Cyberpsychology, behavior and social networking	26	11	823–834	Although social support facilitates coping and recovering from stressful life events, people do not always get the support that they need. Prior research suggests that the way one talks about stressful events to others may influence the support they receive. Given that people are increasingly relying on online communities for social support, this study adopted a person-centered approach (latent profile analysis) to examine how narrative variables related to the motivational themes, emotional content, and organizational structure of randomly sampled support-seeking messages (N = 495) posted on Reddit (r/Anxiety and r/Depression) influenced the quantity (number of comments and post score) and quality (type of support in comments) of support that they received. We identified five distinct narrative profiles of support-seeking posts, which in turn differentially predicted the quality, but not quantity, of social support people received. While commenters provided high levels of emotional support to all forms of posts, we found that coherence was an important determinant of esteem support. A combination of coherence, as well as agency and affective tone, were important determinants of instrumental, informational, and network support. The ways in which one talks about their problems influence the way others support them.
Adler, Gilad; Shahar, Ben; Dolev, Tohar; Zilcha-Mano, Sigal	2018	The Development of the Working Alliance and Its Ability to Predict Outcome in Emotion-Focused	The Journal of nervous and mental disease	206	6	446–454	The study focuses on the alliance of 12 patients receiving emotion-focused therapy for social anxiety. Anxiety symptoms and patient perception of the working alliance were examined weekly. The first eight sessions of each patient were coded for within- and between-sessions alliance levels (1008 segments were coded). At the sample level, the alliance shows linear development over time but high variability between individuals. More than

		Therapy for Social Anxiety Disorder					half the patients showed alliance development consistent with the rupture-resolution pattern. Without accounting for the temporal relationship between alliance and symptoms, alliance significantly predicted symptoms across treatment. When we accounted for the temporal relationship between alliance and symptoms, we found that symptoms can predict alliance but alliance cannot predict symptoms. We obtained the same findings using patient-rated and coded alliance.
Adu, Medard Kofi; Shalaby, Reham; Eboreime, Ejemai; Sapara, Adegboyega; Lawal, Mobolaji A.; Chew, Corina; Daubert, Shelley; Urichuck, Liana; Surood, Shireen; Li, Daniel; Snaterse, Mark; Mach, Mike; Chue, Pierre; Greenshaw, Andrew J.; Agyapong, Vincent I. O.	2023	Apparent Lack of Benefit of Combining Repetitive Transcranial Magnetic Stimulation with Internet-Delivered Cognitive Behavior Therapy for the Treatment of Resistant Depression: Patient-Centered Randomized Controlled Pilot Trial	Brain sciences	13	2		Background: Treatment-resistant depression (TRD) is considered one of the major clinical challenges in the field of psychiatry. An estimated 44% of patients with major depressive disorder (MDD) do not respond to two consecutive antidepressant therapies, and 33% do not respond to up to four antidepressants. Over 15% of all patients with MDD remain refractory to any treatment intervention. rTMS is considered a treatment option for patients with TRD. Likewise, iCBT is evidence-based, symptom-focused psychotherapy recommended for the treatment of TRD. Objective: This study aimed to evaluate the initial comparative clinical effectiveness of rTMS treatment with and without iCBT as an innovative intervention for the treatment of participants diagnosed with TRD. Methods: This study is a prospective two-arm randomized controlled trial. Overall, 78 participants diagnosed with TRD were randomized to one of two treatment interventions: rTMS sessions alone and rTMS sessions plus iCBT. Participants in each group were made to complete evaluation measures at baseline, and 6 weeks (discharge) from treatment. The primary outcome measure was baseline to six weeks change in mean score for the 17-item Hamilton depression rating scale (HAM-D-17). Secondary outcomes included mean baseline to six-

							<p>week changes in the Columbia suicide severity rating scale (CSSRS) for the rate of suicidal ideations, the QIDS-SR16 for subjective depression, and the EQ-5D-5L to assess the quality of health in participants. Results: A majority of the participants were females 50 (64.1%), aged ≥ 40 39 (50.0%), and had college/university education 54 (73.0%). After adjusting for the baseline scores, the study failed to find a significant difference in the changes in mean scores for participants from baseline to six weeks between the two interventions under study on the HAMD-17 scale: $F(1, 53) = 0.15, p = 0.70$, partial eta squared = 0.003, CSSRS; $F(1, 56) = 0.04, p = 0.85$, partial eta squared = 0.001, QIDS-SR16 scale; $F(1, 53) = 0.04, p = 0.61$, partial eta squared = 0.005, and EQ-5D-VAS; $F(1, 51) = 0.46, p = 0.50$, and partial eta squared = 0.009. However, there was a significant reduction in means scores at week six compared to baseline scores for the combined study population on the HAMD-17 scale (42%), CSSRS (41%), QIDS-SR16 scale (35%), and EQ-VAS scale (62%). Conclusion: This study did not find that combined treatment of TRD with rTMS + iCBT (unguided) was superior to treatment with rTMS alone. Our findings do not support the use of combined treatment of rTMS + iCBT for the management of TRD disorders.</p>
Agnello, Irene; Giubellini, Chiara	2021	Clinical experiences during the COVID-19 pandemic	The Journal of analytical psychology	66	3	379–398	<p>Most of the clinical experiences discussed in this article arose from monthly Zoom meetings at Rome's Italian Centre of Analytical Psychology (CIPA). We set up a discussion group in April 2020, one month after lockdown began in Italy, and these monthly online meetings continue to this day. All senior analysts and analysts-in-training at Rome's CIPA, whose backgrounds range from child and adolescent psychotherapy to adult</p>

						<p>psychotherapy and analysis, to sandplay therapy and medicine and psychiatry, have been participating in these meetings. The group discussions focus on the present time and its impact on us, as well as on our relationships with patients. By further developing these reflections during the lockdown in Italy (9 March - 3 May 2020), it is fair to ask whether a sense of unreality, depersonalization, or derealization has occurred, either in the therapist or patient, and if so, whether it is possible that therapists miss the human contact more than clients. We will mainly refer to clinical and personal experiences as our most precious guidelines.</p> <p>La plupart des expériences cliniques discutées dans cet article proviennent de rencontres mensuelles par Zoom à la CIPA, le Centre de Psychologie Analytique Italien, à Rome. Nous avons mis en place en avril 2020 un groupe de discussion, un mois après que le confinement ait commencé en Italie. Ces réunions mensuelles, en ligne, se poursuivent jusqu'à ce jour. Les analystes confirmés et les analystes en formation à la CIPA participent à ces rencontres. Leurs contextes sont variés: de la psychothérapie d'enfants et d'adolescents à la psychothérapie d'adultes et à l'analyse, et également la thérapie par le jeu de sable, la médecine et la psychiatrie. Les discussions se concentrent sur le temps présent et son impact sur nous, et sur nos relations avec nos patients. En poussant plus loin les réflexions durant le confinement en Italie (du 9 mars au 3 mai 2020), il est pertinent de se demander s'il s'est produit un sentiment d'irréalité, de dépersonnalisation ou déréalisation, chez le thérapeute ou chez le patient. Et si c'est le cas, est-il envisageable que le contact humain manque aux thérapeutes plus qu'aux clients? Notre consigne la plus</p>

						<p>analisti-in-formazione presso il CIPA di Roma, i cui background spaziano dalla psicoterapia infantile e adolescenziale alla psicoterapia e analisi degli adulti, alla sandplay therapy, alla medicina e psichiatria. Le discussioni di gruppo si concentrano sull'attualità e sul suo impatto su di noi, nonché sulle nostre relazioni con i pazienti. Sviluppando ulteriormente queste riflessioni durante il lockdown in Italia (9 Marzo - 3 Maggio 2020), è giusto chiedersi se si sia presentato un senso di irrealtà, spersonalizzazione o derealizzazione, sia nel terapeuta che nel paziente e, in caso affermativo, se sia possibile che i terapeuti sentano la mancanza del contatto umano più dei pazienti. Faremo principalmente riferimento alle esperienze cliniche e personali come nostre linee guida più preziose.</p> <p>Большинство клинических примеров, которые мы обсуждаем в этой статье, возникли в ходе ежемесячных встреч в зуме римского Итальянского центра аналитической психологии (CIPA). Мы организовали дискуссионную группу в апреле 2020, через месяц после введения локдауна в Италии, эти ежемесячные встречи продолжаются по сей день. В них принимают участие все старшие аналитики и кандидаты римского сообщества CIPA, работающие в области детской и подростковой психотерапии, психотерапии взрослых и анализа, песочной терапии, медицины и психиатрии. Групповые дискуссии фокусируют внимание на настоящем времени и его влиянии на нас, а также на наших отношениях с пациентами. Дальнейшее развитие этих обсуждений во время локдауна в Италии (9е марта - 3е мая 2020) привело к постановке вопроса: возникает ли у терапевта или пациента чувство нереальности,</p>
--	--	--	--	--	--	---

						<p>деперсонализации или дереализации, возможно ли, что терапевты больше тоскуют по человеческому контакту, чем клиенты. Мы будем преимущественно ссылаться на клинический и личный опыт как наш бесценный проводник в этом вопросе.</p> <p>La mayor parte de la experiencia clínica descrita en este artículo emergió de los encuentros mensuales vía Zoom del Centro de Psicología Analítica de Roma (CIPA). Creamos un grupo de discusión en Abril 2020, un mes después del comienzo del confinamiento, y estos encuentros mensuales virtuales continúan hasta estos días. Todos los analistas con antigüedad, y analistas en formación en la CIPA de Roma, cuyos antecedentes van desde psicoterapia con niños y adolescentes hasta psicoterapia y análisis de adultos, terapia de juego de arena, medicina y psiquiatría, han participado de estos encuentros. La discusión del grupo se focalizó en el tiempo presente y su impacto en todos nosotros, así como en nuestras relaciones con los pacientes. Al continuar desarrollando estas reflexiones surgidas durante el confinamiento en Italia (9 de Marzo - 3 de Mayo 2020), es válido preguntar si ha tenido lugar un sentido de no realidad, despersonalización o desrealización, en el terapeuta o en el paciente, y de ser así, si es posible que los terapeutas hayan extrañado el contacto humano más que los pacientes. Haremos referencia principalmente a experiencias personales y clínicas como nuestras guías más preciosas.</p> <p>新冠疫情期间的临床经验 这篇文章中讨论的大部分临床经验都来自于罗马分析心理学意大利中心 (CIPA)在Zoom上的会谈。2020年4月,我们组建了线上讨论小组,这是在意大利封锁一个月后,这个月度的会面一直持续到了今天</p>
--	--	--	--	--	--	--

							<p>。与会者是CIPA资深或正在受训的分析师, 他们的背景从儿童与青少年心理咨询师到成人心理治疗师与分析师, 从沙盘治疗师到药物和精神科医师。小组的讨论聚焦于当前的状况, 其对我们的影响, 以及其对我们与病人关系的影响。文章进一步讨论了在意大利封锁时期(2020年3月9日-5月3日)所做的反思, 透过这些反思, 来探寻治疗师或是病人, 是否出现了去现实感, 人格解离, 或现实感丧失, 有没有可能治疗师比病人更渴望人际联结。我们主要参考临床和个人的经验, 把这些作为我们最宝贵的指引。.</p>
Aguayo, Joseph; Salomonsson, Björn	2017	THE STUDY AND TREATMENT OF MOTHERS AND INFANTS, THEN AND NOW: MELANIE KLEIN'S "NOTES ON BABY" IN A CONTEMPORARY PSYCHOANALYTIC CONTEXT	The Psychoanalytic quarterly	86	2	383-408	<p>This paper draws on Melanie Klein's (unpublished) observational notes of her infant grandson, written primarily in 1938 and 1939. Apart from moving glimpses into a young family's life, the notes contain astute observations of an infant's behavior and emotions. Compared with Klein's published writings, the style is less theoretical and polemical. Later, in his latency years, Klein's grandson was in analysis with Marion Milner, who in 1952 published a paper drawing on the treatment. The present paper focuses on (1) how observations and treatment of the same child and his family by clinicians in close relationships with each other (Klein, Milner, and Winnicott) fertilized reciprocal influence but also brought into question the validity of Klein's observations, and (2) the relative merits and contributions of various modalities in understanding the infant's psyche, including experimental research, direct observation, parent-infant psychotherapy, and reconstructions from older patients—as occurs, for example, in psychoanalysis.</p>

Aherne, Cian; Coughlan, Barry; Surgenor, Paul	2018	Therapists' Perspectives on Suicide: A Conceptual Model of Connectedness	Psychotherapy research : journal of the Society for Psychotherapy Research	28	5	803–819	<p>BACKGROUND: A sense of disconnection for people who are suicidal seems to be a key construct of previous literature. Therapists' ways of encountering and understanding people who are suicidal have not been previously researched in depth using qualitative methodologies. AIMS: The current study aims to develop a theoretical framework for the role played by connectedness in relation to suicide based on the perspectives of psychotherapists working in the field of suicide intervention. METHOD: Psychotherapists (N = 12) from a suicide intervention service in Ireland were interviewed in relation to connectedness and suicide. The interviews were analysed using Constructivist Grounded Theory. A tentative theoretical model for connectedness in relation to suicide was developed. RESULTS: Therapists view self-disconnect as at the core of suicidality and note that toxic relationships also play a critical role. Therapeutic connection can present as a life-saving paradox for people who are suicidal. Risk of death and therapeutic endeavour may present as challenging dynamics for working with people who are suicidal. Some discussion points include the worth of self-compassion development for people who are suicidal, the rephrasing of "psychotherapy" when trying to save someone's life and the emphasis on relationship skills for all healthcare professionals who encounter people who are suicidal. Clinical or methodological significance of this article: This article is one of the first in which therapists are interviewed about their understandings of suicide and the processes of suicide in the therapeutic space. It offers novel insights about how people who are suicidal present in therapy and what may be contributing to this presentation. The research also gives insights on the</p>
--	------	---	---	----	---	---------	--

							struggles for therapists working with people who are suicidal and who may be ambiguous about the prospect of therapy and connecting. The study also offers important direction for future studies in relation to what requires further discussion and exploration regarding engaging in therapy with people who are suicidal. In addition, the current study can offer previously unexplored insights regarding suicide and therapy that may have the potential to assist in future intervention for people who are risk of killing themselves.
Ahlquist, Lauren R.; Yarns, Brandon C.	2022	Eliciting emotional expressions in psychodynamic psychotherapies using telehealth: a clinical review and single case study using emotional awareness and expression therapy	Psychoanalytic psychotherapy	36	2	124-140	The COVID-19 pandemic and ensuing social distancing requirements resulted in an abrupt transition in the provision of most mental healthcare to telehealth; yet it was, at first, unclear whether patients' emotional expressions - of great import to the success of many psychodynamic therapies - could be facilitated using teletherapy. This article first presents a targeted literature review focused on emotional expressions in psychotherapy and implementing psychodynamic therapy over telehealth and then describes our clinical experience transitioning a psychodynamically-informed, evidence-based, and experiential group treatment for chronic pain, emotional awareness and expression therapy (EAET), to video telehealth at VA Greater Los Angeles Healthcare System. We discuss barriers we encountered in our implementation of EAET over video telehealth but also illustrate the ultimate success of the approach using verbatim excerpts from our therapeutic work, which aim to demonstrate the potential to facilitate powerful emotional expressions over video telehealth when conducting a psychodynamically-informed treatment. We examine the possible applications for video telehealth to maintain emotionally focused,

							psychodynamic psychotherapy administration and enhance its teaching and training. Although we describe limitations of our specific approach, ultimately, our experience supports the potential efficacy of experiential, emotion-focused psychodynamic therapies in a telehealth setting.
Ahmann, Elizabeth; Smith, Katherine; Ellington, Laurie; Pille, Rebecca O.	2019	Health and Wellness Coaching and Psychiatric Care Collaboration in a Multimodal Intervention for Attention-Deficit/Hyperactivity Disorder: A Case Report	The Permanente journal	24			INTRODUCTION: Stimulant medications are the most common treatment for attention-deficit/hyperactivity disorder (ADHD). However, a multimodal approach that includes behavioral interventions may yield better outcomes. Coaching is gaining recognition as a client-centered behavioral intervention for the management of ADHD. OBJECTIVE: To examine the collaboration between ADHD-focused health and wellness coaching and psychiatric care to support a client's improved self-management of ADHD. METHODS: Using the internationally developed CARE (CASE REport) guidelines designed to improve transparency and accuracy in health research reporting, this case report is based on a systematic review of data collected from the point of care. RESULTS: An 8-week collaboration between a psychiatrist and a health and wellness coach both expanded what the psychiatrist had been able to achieve alone in working with a client with ADHD and resulted in client improvement in self-efficacy and various functional impairments, including organizational skills and academic achievement. The client achieved her goal of resuming graduate studies and both integrated and maintained her behavioral changes for more than 6 months, successfully graduating from her program. DISCUSSION: This is the first case report, to our knowledge, describing the process of coaching for ADHD and exploring its integration with psychiatric care. It

							illustrates beneficial outcomes and the promising role of health and wellness coaching in assisting individuals with ADHD in achieving successful behavior change. The client in this case report made progress that was sustained beyond the 6-month mark, an important milestone in the trajectory of behavior change. CONCLUSION: This case report suggests that health and wellness coaching can be effective in supporting beneficial outcomes and can be useful in the multimodal management of ADHD.
Aich, Gernot; Kuboth, Christina; Behr, Michael	2016	Beratung mit Eltern nach dem Gmnder Modell zur Gesprächsführung (GMG)	Gesprchspsych ootherapie und Personzentrierte Beratung	47	4	228–233	Das Gmndner Modell zur Gesprächsführung (GMG) als Grundlage zum Fhren von Elterngesprchen im schulischen Kontext wird vorgestellt. Es verbindet personzentriertes, transaktionsanalytisches und lsungsorientiertes Vorgehen zu einem integrierenden Konzept. Nach einer Beschreibung der theoretischen Hintergrnde des Modells werden die Module eines fr Lehrkrfte entwickelten Trainings dieser Gesprächsführungstechnik vorgestellt. Anschließend wird der Prozesscharakter des Modells beleuchtet, die Anwendung des GMG bei Elterngesprchen konkretisiert und ein Einblick in Evaluationsergebnisse gegeben.
Alayoubi, Alaadin; Zidan, Ahmed; Asfari, Sarah; Ashraf, Muhammad; Sau, Lee; Kopcha, Michael	2022	Mechanistic understanding of the performance of personalized 3D-printed cardiovascular polypills: A case study of patient-centered therapy	International journal of pharmaceutics	617		121599	The 3D printing has become important in drug development for patient-centric therapy by combining multiple drugs with different release characteristics in a single polypill. This study explores the critical formulation and geometric variables for tailoring the release of Atorvastatin and Metoprolol as model drugs in a polypill when manufactured via pressure-assisted-microextrusion 3D printing technology. The effects of these variables on the extrudability of printing materials, drug release and other quality characteristics of polypills were studied employing a definitive screening design. The

							extrudability of printing materials was evaluated in terms of flow pressure, non-recoverable strain, compression rate, and elastic/plastic flow. The extrudability results helped in defining an operating space free of printing defects. The Atorvastatin compartment of polypill consisted of mesh-shaped layers while Metoprolol compartment consisted of a core surrounded by a release controlling shell with a hydrophobic septum between the two compartments. The results indicated that both the formulation and geometric variables govern the drug release of the polypill. Specifically, the use of HPMC E3 matrix, and a 2 mm distance between the strands at a weaving angle of 90° were critical in achieving the desired immediate-release profile of Atorvastatin. The core and shell design primarily determined the desired extended-release profile of Metoprolol. The carbopol and HPMC K100 concentration of 1% in the core and 10% in the shell and the number of shell layers in Metoprolol compartment were critical for achieving the desired Metoprolol dissolution. Polymer and Metoprolol content of the shell and shell-thickness affected the mechanical strength of the polypills. In conclusion, the 3D printing provides the flexibility for independently tailoring the release of different drugs in the same dosage form for patient centric therapy, and both the formulation and geometric parameters need to be optimized to achieve desired drug release.
Albaugh, Matthew D.; Hudziak, James J.; Orr, Catherine; Spechler, Philip	2019	Amygdalar reactivity is associated with prefrontal cortical thickness in a	PloS one	14	5	e0216152	In structural neuroimaging studies, reduced cerebral cortical thickness in orbital and ventromedial prefrontal regions is frequently interpreted as reflecting an impaired ability to downregulate neuronal activity in the amygdalae. Unfortunately, little research has been conducted in order to test this conjecture. We examine

<p>A.; Chaarani, Bader; Mackey, Scott; Lepage, Claude; Fonov, Vladimir; Rioux, Pierre; Evans, Alan C.; Banaschewski, Tobias; Bokde, Arun L. W.; Bromberg, Uli; Büchel, Christian; Quinlan, Erin Burke; Desrivières, Sylvane; Flor, Herta; Grigis, Antoine; Gowland, Penny; Heinz, Andreas; Ittermann, Bernd; Martinot, Jean-Luc; Martinot, Marie-Laure Paillère; Nees, Frauke; Orfanos, Dimitri Papadopoulos; Paus, Tomáš; Poustka, Luise; Millenet,</p>		<p>large population-based sample of adolescents</p>				<p>the extent to which amygdalar reactivity is associated with cortical thickness in a population-based sample of adolescents. Data were obtained from the IMAGEN study, which includes 2,223 adolescents. While undergoing functional neuroimaging, participants passively viewed video clips of a face that started from a neutral expression and progressively turned angry, or, instead, turned to a second neutral expression. Left and right amygdala ROIs were used to extract mean BOLD signal change for the angry minus neutral face contrast for all subjects. T1-weighted images were processed through the CIVET pipeline (version 2.1.0). In variable-centered analyses, local cortical thickness was regressed against amygdalar reactivity using first and second-order linear models. In a follow-up person-centered analysis, we defined a "high reactive" group of participants based on mean amygdalar BOLD signal change for the angry minus neutral face contrast. Between-group differences in cortical thickness were examined ("high reactive" versus all other participants). A significant association was revealed between the continuous measure of amygdalar reactivity and bilateral ventromedial prefrontal cortical thickness in a second-order linear model ($p < 0.05$, corrected). The "high reactive" group, in comparison to all other participants, possessed reduced cortical thickness in bilateral orbital and ventromedial prefrontal cortices, bilateral anterior temporal cortices, left caudal middle temporal gyrus, and the left inferior and middle frontal gyri ($p < 0.05$, corrected). Results are consistent with non-human primate studies, and provide empirical support for an association between reduced prefrontal cortical thickness and amygdalar reactivity. Future research will likely benefit from investigating the degree to which</p>

Sabina; Fröhner, Juliane H.; Smolka, Michael N.; Walter, Henrik; Whelan, Robert; Schumann, Gunter; Potter, Alexandra S.; Garavan, Hugh							psychopathology qualifies relations between prefrontal cortical structure and amygdalar reactivity.
Alessandrini, Kristyna	2023	Small things—‘It felt like love’— The experience of being deeply moved in therapy: Clients' stories of the small things that matter in therapy	Couns and Psychother Res (Counselling and Psychotherapy Research)				
Alessi, Edward J.; Dillon, Frank R.; van der Horn, Rebecca	2019	The therapeutic relationship mediates the association between affirmative practice and psychological well-being among lesbian, gay, bisexual, and queer clients	Psychotherapy	56	2	229–240	In this study, we tested a conceptual model through which lesbian, gay, bisexual, and queer (LGBQ) clients' perceptions of their therapists' affirmative practices and the therapeutic relationship (i.e., working alliance and the real relationship) would correlate with psychological well-being. We hypothesized that the therapeutic relationship would mediate the relation between clients' perceptions of their therapists' affirmative practices and psychological well-being while controlling for precounseling distress, client age, client race/ethnicity, number of psychotherapy sessions, and therapist gender. A nationwide sample of 184 LGBQ individuals was recruited through the Internet. Participants ranged in age

							<p>from 18 to 64 years old (Mage = 27.57; SD = 8.50), and the majority identified as female (65.8%) and White (77.2%). Structural equation modeling showed that participants' perceptions of their therapists' affirmative practices were associated with psychological well-being ($\beta = .21, p < .01$). Findings also indicated that the therapeutic relationship mediated the association between clients' perceptions of therapists' affirmative practices and psychological well-being ($\beta = .34, p < .001, 95\%$ confidence interval [.15, .52]). More specifically, practicing affirmatively was correlated with a stronger therapeutic relationship, which was associated with higher levels of psychological well-being for LGBQ clients. Hence, these findings inform and encourage advancements in LGBQ affirmative psychotherapy research, practice, and training. (PsycINFO Database Record (c) 2019 APA, all rights reserved)</p>
Algristian, Hafid	2019	Expressive Writing as Brief Psychotherapy	Open access Macedonian journal of medical sciences	7	16	2602–2606	<p>AIM: To analyse the effect of expressive writing in three selected cases. METHODS: Case studies presented from three psychiatric patients in a hospital-based outpatient clinic in Surabaya, Indonesia, between May 2017 and July 2018. Clinical changes have been observed and reported. Three patients were selected based on the possibility of whether they were able to or not to participate in similar cognitive therapy. These three cases were considered to represent a diagnosis for the psychotic and non-psychotic spectrum. The first case was a male with suicidal depression, the second was a woman with Suicidal Depression, and the third was schizophrenic woman elderly with auditory hallucinations. Expressive writing was formulated from literature studies and then implemented in these patients. Clinical changes were observed both associated with a reduction in symptoms</p>

							<p>as well as new symptoms. These non-directive measures allowed the author to observe the therapeutic effects and side effects of the intervention given. RESULTS: Three cases were analysed. Targets were determined by patients themselves without author's intervention. Each patient underwent 10 sessions in minimum and 32 sessions in maximum, from once per week to once per two weeks, and was stopped after it was considered reaching or approaching the desired target, or if unwanted side effects appeared. Main changes were "father hunger" symptom decreased in the first patient, self-esteem increased in the second patient, and cope with auditory hallucination in the third patient. Few adverse events also have been recorded such as masturbation as an obsession ritual of the first patient, possibly provoked double-identity symptom in the second patient and mental fatigue in the elderly in the third patient. CONCLUSION: Over six months of implementation, expressive writing show desirable results, yet some side effects in patients still need to be aware of.</p>
<p>Alighieri, Cassandra; Bettens, Kim; Verbeke, Jolien; van Lierde, Kristiane</p>	2023	<p>'Sometimes I feel sad': A qualitative study on children's perceptions with cleft palate speech and language therapy</p>	<p>International journal of language & communication disorders</p>	58	5	1526–1538	<p>BACKGROUND Evidence-based speech therapy involves the integration of (1) the scientific evidence for therapy with (2) the perspectives of clinicians concerning therapy and (3) the perspectives of patients about therapy. The cleft literature has already paid attention to the first two cornerstones of evidence-based speech therapy. Much less is known about how children perceive cleft speech therapy.</p> <p>AIMS The purpose of the current qualitative study was to investigate the perceptions, emotions and expectations of Flemish-speaking Dutch children with a cleft (lip and) palate (CP ± L), aged 5-12 years, with regard to the speech</p>

						<p>therapy they receive. In this study, a focus was made on speech therapy to eliminate compensatory cleft speech errors.</p> <p>METHODS & PROCEDURES</p> <p>Six children with a CP ± L, aged between 5 and 12 years, were included in this study. Child-friendly semi-structured interviews were conducted using a participatory, art-based qualitative approach. This means that the 'play and puppets technique' and 'draw-write and photo-elicitation technique' were used to guide the children through the interviews. Data derived from these interviews were analysed using an inductive thematic approach. Trustworthiness of the data was achieved by applying researcher triangulation, negative case analysis and an audit trail.</p> <p>OUTCOMES & RESULTS</p> <p>Analyses of the interviews revealed three major themes of importance to the children: (1) treatment values, (2) treatment practices and (3) treatment outcomes. Each theme was divided into different subthemes. The theme 'treatment values' consisted of the subthemes expectations and emotions around therapy and interference with daily living. Information flow, therapy content, confirmation and rewards, parents' attendance, therapy intensity, and homework were subthemes of the major theme 'treatment practices'. The theme 'treatment outcomes' was divided into two subthemes, namely speech improvement and peers' reactions.</p> <p>CONCLUSIONS & IMPLICATIONS</p> <p>Most children had positive attitudes towards speech therapy: it was 'something they liked' and 'something fun'. If children had negative attitudes they were related to having a fear of making mistakes during therapy. Children</p>
--	--	--	--	--	--	--

						<p>had clear expectations of the purpose of speech therapy. Speech therapy should 'help' improve their speech and make it more understandable to others. The children in this sample made some suggestions to decrease the experienced burden related to speech therapy. The results of this study will help to better tailor speech therapy programmes to the needs and experiences of children with a CP ± L.</p> <p>WHAT THIS PAPER ADDS</p> <p>What is already known on the subject Evidence-based speech therapy involves the integration of (1) the scientific evidence for therapy with (2) the perspectives of clinicians concerning therapy and (3) the perspectives of patients and their families about therapy. The cleft literature has already paid attention to the first two cornerstones of evidence-based speech therapy. Different studies investigated the perspectives of SLPs and parents with regard to cleft palate speech therapy. However, much less is known about the children's own experiences with and perceptions around this speech therapy. What this study adds to existing knowledge This study used a qualitative research design to investigate the perceptions, emotions and expectations of children with a cleft (lip and) palate, aged 5-12 years, with regard to the speech therapy they receive. Speech therapy needed to focus on the elimination of compensatory speech errors. This study provides knowledge on the speech therapy-related experiences of children with a cleft palate. What are the potential or actual clinical implications of this work? Children in this sample made some concrete suggestions to decrease the experienced burden related to cleft speech therapy, for example, integration of school work during therapy sessions and practising on the level</p>
--	--	--	--	--	--	---

							of spontaneous speech. The results of this study help us to better tailor speech therapy programmes to the needs and experiences of children with a CP ± L.
Al-Jabari, Rawya; Murrell, Amy R.; Callahan, Jennifer L.; Cox, Randall J.; Lester, Ethan G.	2019	Do distress level and waitlists impact termination in a training clinic?	Training and Education in Professional Psychology	13	2	127-137	Premature termination (PT) is a substantial problem in psychology training clinics, resulting in adverse effects for both clients and psychotherapists in training. Although a large meta-analysis found the rate of PT to fall at 19.7% across varied mental health care settings, moderation analyses revealed much higher rates of premature termination were specific to those being treated in campus mental health settings (Swift & Greenberg, 2012). A subsequent multisite study was able to focus specifically on psychology training clinic clients (as opposed to university counseling centers, etc.) and found that the rate of PT among clients in those clinics was ~70% (Callahan et al., 2014). Other single-site studies in psychology training clinics have reported rates of nearly 80% (Aubuchon-Endsley & Callahan, 2009; Swift, Callahan, & Levine, 2009). In the current sample (N = 524) of adult clients who were treated by trainees across three accredited doctoral (Ph.D.) programs in a traditional university-based psychology training clinic, the rate of PT was found to fall in the range of 63% (based on trainees' subjective appraisals of client outcome) to 69.9% (based on scores from a routine outcome tracking measure). Neither client demographic variables (e.g., age, sex, race/ethnicity) nor psychotherapist training variables (e.g., years in doctoral program, direct client contact hours) were significantly associated with PT. Exploration of psychotherapy variables (e.g., alliance) and clinic variables (e.g., waitlist duration) revealed only small effects. Significant work remains in understanding the etiology of the high premature termination rates that are

							consistently demonstrated in psychology training clinics. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Allan, Blake A.; Kim, Taewon; Liu, Tracie Y.; Deemer, Eric D.	2020	Moderators of involuntary part-time work and life satisfaction: A latent deprivation approach	Professional Psychology: Research and Practice	51	3	257–267	Work plays a central role in people’s lives, and professional psychologists have a stake in understanding how different work statuses affect people’s well-being. Involuntary part-time work, in particular, represents a potentially harmful work status that professional psychologists can address with the appropriate evidence. Therefore, using latent deprivation theory as a guide, this study examined financial and experiential deprivation as moderators of the relation between involuntary part-time work and life satisfaction in a large sample of U.S. college graduates (N = 61,251). We also examined mean differences in financial deprivation, experiential deprivation, and life satisfaction between employment status groups and examined group differences in the rates of involuntary part-time work. We found that involuntary part-time workers had greater financial and experiential deprivation and lower life satisfaction than other employment groups, except for people who were unemployed. We also found that financial and experiential deprivation moderated the relation between involuntary part-time work and life satisfaction. Specifically, people with lower financial and experiential deprivation were protected from the negative relation between involuntary part-time work and life satisfaction. Finally, we found that the rates of involuntary part-time work were higher for marginalized groups, such as women, people of color, and people with a lesbian, gay, bisexual, or transgender identity. This study highlights the relation between involuntary part-time work and life satisfaction, the roles of financial and experiential

							deprivation, the importance of qualifying employment statuses on a continuum, and potential targets of intervention for professional psychologists. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Allan, Robert	2019	Teaching and learning evidence-based practices: Promoting dialogue for counsellors and psychotherapists	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	3	206–213	
Allan, Robert; Wiebe, Stephanie A.; Johnson, Susan M.; Piaseckyj, Olena; Campbell, T. Leanne	2021	Practicing Emotionally Focused Therapy online: Calling all relationships	Journal of marital and family therapy	47	2	424–439	In the midst of a global pandemic, couples are dealing a range of impacts that call for a cohesive unit while the virus frays at the edges of our most important relationships. Emotionally Focused Therapy (EFT) is an evidence-based approach to working with relationships rooted in attachment theory. As a process-oriented psychotherapy, EFT is an ideal approach to working with relationships during this pandemic helping to solidify an "in it together" approach required to survive both as a couple and the pandemic. In this paper, we briefly review the adaptations for moving a couple therapy practice online through an EFT lens, drawing on an EFT macro-intervention called the "Tango" as a focus in this process. We conclude the paper with a case example providing the reader with an illustration of the process and ideas for what to pay attention to when working online with a couple from an EFT perspective. 2021 American Association for Marriage and Family Therapy.

Alldredge, Cameron T.; Elkins, Gary R.	2023	Adaptive Experiential Theory of Hypnosis	The International journal of clinical and experimental hypnosis	71	3	165-175	State and nonstate theories of hypnosis have dominated the field for decades and helped advance hypnosis clinically and scientifically. However, they fall short in various ways including insufficient consideration of unconscious/experiential processes. The authors' new theory is predicated on Epstein's cognitive-experiential self-theory, a dual-process model that provides a comprehensive understanding of the rational system and the experiential system and highlights that, although they interact synergistically, their features and modes of operation differ greatly. The rational system, influenced by logic and reason, is demanding of cognitive resources and operates effortfully with minimal affect. In contrast, the experiential system is emotionally driven, associative, and encodes reality in images and feelings without conscious effort. Our theory, the adaptive experiential theory, posits that complex hypnotic responding is attributable to an individual's ability to adapt and deliberately shift from processing primarily within the rational system to the experiential system. Greater association with the experiential system yields alterations in processing reality, which allows hypnotic suggestions to be internalized and enacted without excessive interference from the rational system.
Allen, Brian; Hoskowitz, Natalie Armstrong	2017	Structured Trauma-Focused CBT and Unstructured Play/Experiential Techniques in the Treatment of Sexually Abused	Child maltreatment	22	2	112-120	Structured, trauma-focused cognitive-behavioral therapy (CBT) techniques are widely considered an effective intervention for children who experienced sexual abuse. However, unstructured (i.e., nondirective) play/experiential techniques have a longer history of widespread promotion and are preferred by many practicing clinicians. No evidence is available, however, to determine how the integration of these techniques impacts treatment outcome. In this study, community-

		Children: A Field Study With Practicing Clinicians					based clinicians who received training in a structured, trauma-focused cognitive-behavioral intervention administered pretreatment and posttreatment evaluations to 260 sexually abused children presenting with elevated posttraumatic stress. In addition, they completed a questionnaire describing the treatment techniques implemented with each child. Overall, significant improvement was observed for each of the six clinical outcomes. Regression analyses indicated that technique selection was a significant factor in posttreatment outcome for posttraumatic stress, dissociation, anxiety, and anger/aggression. In general, a greater utilization of the structured CBT techniques was related to lower posttreatment scores, whereas a higher frequency of play/experiential techniques was associated with higher posttreatment scores. However, no interaction effects were observed. The implication of these findings for clinical practice and future research are examined.
Almeida, Susana N.; Elliott, Robert; Silva, Eunice R.; Sales, Célia M. D.	2022	Emotion-focused therapy for fear of cancer recurrence: A hospital-based exploratory outcome study	Psychotherapy	59	2	261–270	Fear of cancer recurrence (FCR) is a main concern for most cancer survivors and can bring significant distress impacting well-being and quality of life. Although other psychological approaches have been developed for dysfunctional FCR, based on previous research, emotion-focused therapy (EFT) might also be a relevant intervention for treating this concern. A total of 17 adults with a cancer diagnosis and presenting FCR among other cancer-related concerns were offered EFT, delivered in a regular practice in a cancer hospital (mean number of sessions = 13, range: 4–25). Outcome and process instruments were used to assess general psychological distress, client-generated outcome items, and helpful and hindering aspects of therapy. Significant pre–post

							outcome differences were found, both for client-generated ($d = 1.53$) and standard ($d = .88$) measures, with no cases of reliable deterioration, although most patients did not show clinically significant change by the end of therapy. The most frequent helpful in-session processes were client verbal expression of experience and work on parts of self; the most common immediate session impacts were positive feelings and self-realizations. EFT may be a useful alternative treatment for FCR. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Almeida, Susana N.; Elliott, Robert; Silva, Eunice R.; Sales, Célia M. D.	2024	Developing an emotion-focused therapy model for fear of cancer recurrence: A case-level task analysis	Couns and Psychother Res (Counselling and Psychotherapy Research)	24	1	180–189	
Alphonsus, Elizabeth; Fellin, Lisa C.; Thoma, Samuel; Galbusera, Laura	2023	They have taken out my spinal cord: an interpretative phenomenological analysis of self-boundary in psychotic experience within a sociocentric culture	Frontiers in psychiatry	14		1215412	INTRODUCTION: In the tradition of phenomenological psychiatry, schizophrenia is described as a disturbance of the minimal self, i.e. the most basic form of self-awareness. This disturbance of the minimal self at the individual level is assumed to precede the intersubjective disturbances such as boundary weakening. However, the role of intersubjective disturbances in the emergence and recovery of schizophrenic experience still remains an open question. This phenomenological study focuses on how encounters with others shape self-experience during from psychosis by analyzing this process from the perspective of cultural differences, which in current research is especially under-researched. While most phenomenological accounts are based on first person-

							accounts from Western, individualist cultures where the self is conceived and experienced as separate to others, the present study qualitatively investigates psychotic experiences of patients from Jaffna, Sri Lanka. METHOD: Semi-structured interviews were conducted with three participants with a diagnosis of schizophrenia or first episode psychosis. The interviews were transcribed and analyzed using interpretative phenomenological analysis (IPA). Eight group experiential themes were identified across interviews. RESULTS: The data suggest that intersubjective processes of boundary weakening such as invasiveness and hyperattunement may shape minimal self-experience and more specifically contribute to a mistrust of the own senses and to hyper-reflexivity. Interestingly, boundary weakening yields pervasive emotions and can be experienced as a threat to the whole social unit. On the one hand, the strengthening of self-other-boundary was achieved through opposition, closedness and withdrawal from others. On the other hand, this study suggests that the re-opening of self-other-boundaries in response to the crisis may help establish connectedness and may lead to recovery.
Altendorfer-Kling, Ulrike	2021	Digitale Medien als Therapieebne und Intermediobjekte in der Therapie von traumatisierten Kindern und Jugendlichen. Einsatz von	Zeitschrift fr Psychodrama und Soziometrie	20	Suppl 1	157-171	Dieser Beitrag der Zeitschrift fr Psychodrama und Soziometrie setzt sich mit der Frage auseinander, wie wir digitale Medien in der Psychodramatherapie mit Kindern und Jugendlichen wirkungsvoll zum Einsatz bringen knnen. In Krisenzeiten ist es fr uns Menschen besonders wichtig, den Kontakt zueinander aufrechterhalten, einander untersttzen und voneinander lernen zu knnen. In diesem Beitrag wird ein flexibler Umgang mit den neuen technischen Mglichkeiten gezeigt, die zur Erweiterung der Therapiemethode Psychodrama fhren und besonders in

		Smartphone und Co. als Therapietools mit Kindern und Jugendlichen, Fallvignetten aus der psychotherapeutischen Praxis					der Traumatherapie hilfreich sind. (c) Springer Fachmedien Wiesbaden GmbH
Alter, David S.; Sugarman, Laurence Irwin	2017	Reorienting Hypnosis Education	The American journal of clinical hypnosis	59	3	235-259	The legacy model of professional clinical hypnosis training presents a restrictive frame increasingly incompatible with our evolving understanding of psychobiology, health, and care. Emerging science recognizes human experience not as disease and diagnosis, but as manifestations of individual, uniquely-endowed, adaptively self-regulating systems. Hypnosis is a particularly well-suited discipline for effecting beneficial change in this paradigm. Training in clinical hypnosis must progress from the current linearly-structured, diagnosis-based, reductionist model toward a more responsive, naturalistic, and client-centered curriculum in order to remain relevant and accessible to clinicians beginning to integrate it into their practices. To that end, this article extends Hope and Sugarman's (2015) thesis of hypnosis as a skill set for systemic perturbation and reorientation to consider what those skills may be, the principles on which they are based, and how they may be taught. Parsing a clinical vignette reveals how incorporation of novelty and uncertainty results in less restrictive and more naturalistic hypnotic encounters that, in response to client-generated cues, elicit psychophysiological plasticity. This disruptive

							hypnosis education and training framework extends the utility and benefit of applied clinical hypnosis.
Althfer, Luigi	2017	Die Radikale Therapie	Zeitschrift fr Transaktionsanalyse	34	1	44-64	Vorgestellt wird die Radikale Therapie (RT) - ein selbstorganisiertes Gruppentherapieverfahren, welches konzeptionell auf der Radical Psychiatry, der Transaktionsanalyse und dem Co-Counseling basiert. Nach einem Abriss der Entstehungsgeschichte der RT wird der Stellenwert der variierenden Rollen der Teilnehmenden aufgezeigt. Im Rahmen der Hintergrnde der RT wird auf die Entfremdungstheorie, den Befreiungsansatz zur Auflsung von Entfremdung, stereotype Geschlechterrollenmuster als spezifische Form der Entfremdung und die politische Dimension des Privaten eingegangen. Anschlieend wird die Praxis der RT vorgestellt und es werden Potenzial und Grenzen aufgezeigt.
Althof, Stanley E.; Needle, Rachel B.	2022	Treating Low Sexual Desire in Men				32-39	Summary This chapter focuses on the assessment and treatment of low sexual desire in men. Low sexual desire in men can represent a complex amalgam of interrelated biological, psychological, interpersonal, and contextual variables that combine to produce distressing symptoms both for the man and for his partner. Psychosexual evaluation goes beyond traditional psychological assessment to examine the man's or couple's sexual history, current sexual practices, relationship quality and history, emotional health, and contextual factors. Each of these variables requires careful evaluation. Psychotherapy outcome studies for men with low sexual desire are scarce. In fact, there are no placebo-controlled, randomized outcome trials for psychotherapeutic interventions; yet, there are many evidenced-based studies of men with androgen deficiency who receive testosterone (T) replacement.

							Educational interventions, values clarification, or suggestions may be useful in dealing with contextual factors responsible for men's low sexual desire.
Alton, Gord	2020	Toward an Integrative Model of Psychospiritual Therapy: Bringing Spirituality and Psychotherapy Together	The journal of pastoral care & counseling: JPCC	74	3	159-165	As a supervisor-educator for the Canadian Association of Spiritual Care, my primary task is to help developing spiritual care providers and psychospiritual therapists learn how to use psychotherapy within the field of spiritual care. The purpose of this essay is to share a psychospiritual model that I teach my students that helps them see how psychospiritual therapy is a form of spiritual practice that helps their clients experience healing from the sacred.
Amole, Marlissa C.; Cyranowski, Jill M.; Conklin, Laren R.; Markowitz, John C.; Martin, Stacy E.; Swartz, Holly A.		Therapist use of specific and nonspecific strategies across two affect-focused psychotherapies for depression: Role of adherence monitoring	Journal of Psychotherapy Integration	27	3		Psychotherapists routinely use both specific and nonspecific strategies to deliver empirically supported treatments (ESTs). Psychotherapy adherence monitoring has traditionally focused on assessing therapist use of EST-specific strategies (to distinguish between ESTs), paying less attention to nonspecific techniques common to multiple psychotherapies. This study used the Collaborative Study Psychotherapy Rating Scale (CSPRS) to evaluate therapist use of both specific and nonspecific techniques in 2 affect-focused ESTs for depression. Blinded raters evaluated 180 recorded sessions of interpersonal psychotherapy (IPT) and brief supportive psychotherapy (BSP). Because IPT and BSP both emphasize attention to affective states and developing a warm therapy relationship, we expected overlap across scales measuring therapist warmth, empathy, and focus on feelings. In contrast, we expected differences in scales measuring therapist directiveness, as well as IPT- and BSP-specific interventions. Results showed raters displayed good interrater reliability on primary subscales and could discriminate between 2 treatments with

						considerable overlap. Both IPT and BSP therapists used similarly high levels of nonspecific, facilitative interventions. Expectedly, IPT therapists were more directive and used more IPT-specific strategies, while BSP therapists utilized more nondirective, supportive strategies. Unexpectedly, BSP therapists showed greater focus on feelings than IPT therapists. Exploratory analyses suggested that greater focus on feelings in early sessions was associated with greater depressive symptom reduction in the first 8 weeks of treatment for both ESTs. Additional treatment adherence research is needed to investigate both shared and distinctive features of ESTs, as well as the effect of the relative use of specific versus nonspecific interventions on psychotherapy outcomes. Amsalem, Doron; Lopez-Yianilos, Andrea; Lowell, Ari; Pickover, Alison M.; Arnon, Shay; Zhu, Xi; Suarez-Jimenez, Benjamin; Ryba, Matt; Bergman, Maja; Such, Sara; Zalman, Hemrie; Sanchez-Lacay, Arturo; Lazarov, Amit;		Treatment dropout among veterans and their families: Quantitative and qualitative findings	Psychological Trauma: Theory, Research, Practice, and Policy	14	4	Background: Psychotherapy noncompletion rates for veterans and their families are high. This study sought to (a) measure noncompletion rates of such patients at a university-based treatment center, (b) compare veteran and family member attrition rates, (c) identify dropout predictors, and (d) explore clinicians' perspectives on treatment noncompletion. Method: Using quantitative and qualitative approaches, we analyzed demographic and clinical characteristics of 141 patients (90 military veterans; 51 family members) in a university treatment center. We defined dropout as not completing the time-limited therapy contract. Reviewing semistructured interview data assessing clinicians' perspectives on their patients' dropout, three independent raters agreed on key themes, with interrater coefficient kappa range .74 to 1. Results: Patient attrition was 24%, not differing significantly between veterans and family members.

Markowitz, John C.; Neria, Yuval							<p>Diagnosis of major depression (MDD) and exposure-based therapies predicted noncompletion, as did higher baseline Hamilton Depression Rating Scale (HDRS) total scores, severe depression (HDRS > 20), lack of Beck Depression Inventory weekly improvement, and history of military sexual trauma. Clinicians mostly attributed noncompletion to patient difficulties coping with intense emotions, especially in exposure-based therapies. Conclusion: Noncompletion rate at this study appeared relatively low compared to other veteran-based treatment centers, if still unfortunately substantial. Patients with comorbid MDD/PTSD and exposure-based therapies carried greater noncompletion risk due to the MDD component, and this should be considered in treatment planning. Ongoing discussion of dissatisfaction and patient discontinuation, in the context of a strong therapeutic alliance, might reduce noncompletion in this at-risk population. Amtmann, Dagmar; Bamer, Alyssa M.; Alschuler, Kevin N.; Bocell, Fraser D.; Ehde, Dawn M.; Jensen, Mark P.; Johnson, Kurt; Nery-Hurwit, Mara B.; Salem, Rana; Silverman, Arielle; Smith,	2020	Development of a resilience item bank and short forms	Rehabilitation Psychology	65	2	145-157	<p>Purpose: The purpose of this study was to develop a publicly available, psychometrically sound item bank and short forms for measuring resilience in any population, but especially resilience in individuals with chronic medical conditions or long-term disability. Research Methods: A panel of 9 experts including disability researchers, clinical psychologists, and health outcomes researchers developed a definition of resilience that guided item development. The rigorous methodology used focus groups, cognitive interviews, and modern psychometric theory quantitative methods, including item response theory (IRT). Items were administered to a sample of people with chronic medical conditions commonly associated with disability (N = 1,457) and to a</p>

Amanda E.; Terrill, Alexandra L.; Molton, Ivan							<p>general population sample (N = 300) representative of the United States general population with respect to age, gender, race, and ethnicity. Results: The final item bank includes 28 items calibrated to IRT with the scores on a T-metric. A mean of 50 represents the mean resilience in the general population sample. Four and eight item short forms are available, and their scores are highly correlated with the item bank score ($r \geq .94$). Reliability is excellent across most of the resilience continuum. Initial analyses provide strong support for validity of the score.</p> <p>Conclusions: The findings support reliability and validity of the University of Washington Resilience Scale (UWRS) for assessing resilience in any population, including individuals with chronic health conditions or disabilities. It can be administered using computerized adaptive testing or by short forms. (PsycInfo Database Record (c) 2021 APA, all rights reserved)</p>
An, Mira; Kivlighan Jr., Dennis M.; Hill, Clara E.	2023	Working alliance after transferring from one therapist to another in a training clinic: Influence of therapist attachment style	Journal of Counseling Psychology	70	1	67–80	<p>This study investigated how client working alliance changed after transferring from one therapist to another: (a) When pre- and post-transfer therapists' attachment anxiety/avoidance were congruently higher or lower and (b) when the pretransfer therapists' attachment anxiety/avoidance were more or less discrepant from the posttransfer therapists. A Tau-U analysis and a multilevel polynomial regression and response surface analysis were used to analyze longitudinal data about 23 transferred clients in open-ended psychodynamic psychotherapy with doctoral-level therapist trainees (n = 29). When first and second therapists' attachment anxiety/avoidance levels were congruent, the higher the two therapists' attachment anxiety and avoidance levels were, the greater was the decrement in clients' ratings of working alliance after transfers. When first and second</p>

							therapists' attachment anxiety/avoidance levels were discrepant from each other, the more the first and second therapists' attachment were different from each other in terms of anxiety, the greater decrement in clients' ratings of working alliance there was after transfers. Meanwhile, the more the two therapists' attachment avoidance levels were different from each other, the less decrement in clients' ratings of working alliance there was after transfers. Therefore, the attachment orientations of the pre- and post-transfer therapists combined to influence client working alliance after transfers. Limitations and implications of the present research are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Anderberg, Emily; Cox, Jonathan C.; Neeley Tass, E. Shannon; Erikson, David M.; Gabrielsen, Terisa P.; Warren, Jared S.; Cline, Jared; Petersen, Devin; South, Mickle	2017	Sticking with it: Psychotherapy outcomes for adults with autism spectrum disorder in a university counseling center setting	Autism research : official journal of the International Society for Autism Research	10	12	2048–2055	UNLABELLED Young adults with autism spectrum disorders (ASD) experience high rates of comorbid mental health concerns in addition to distress arising from the core symptoms of autism. Many adults with ASD seek psychological treatment in outpatient facilities in their communities that are not specifically geared toward individuals with ASD. However, few studies have looked at the effectiveness of standard psychotherapeutic care in adults with ASD. This study aimed to discover how individuals with ASD fare in psychotherapy within a college counseling setting, compared to their neurotypical peers. Clients with ASD (n = 76) or possible ASD (n = 91) were retrospectively identified from counseling center case notes. Data from the Outcome Questionnaire-45 (OQ) were retrieved for each therapy session as a measure of client distress. Clients with ASD showed no difference in level of distress at intake compared to their neurotypical peers (n = 21,546), and

							<p>improved about the same amount from pre- to post-treatment. However, students with ASD stayed in treatment for significantly more sessions than neurotypical clients, and took significantly longer to achieve maximum improvement on OQ reports. Results are discussed with implications for university and other community based treatment settings. <i>Autism Res</i> 2017, 10: 2048-2055. © 2017 International Society for Autism Research, Wiley Periodicals, Inc.</p> <p>LAY SUMMARY</p> <p>This study aimed to discover how individuals with autism spectrum disorders (ASD) fare in psychotherapy within a university counseling setting, compared to their neurotypical peers. Clients with ASD showed no difference in level of distress at intake compared to their neurotypical peers, and improved about the same amount from pre- to post-treatment. However, students with ASD stayed in treatment for significantly more sessions than neurotypical clients, and took significantly longer to achieve maximum improvement on Outcome Questionnaire-45 reports.</p>
Anders, Christopher; Kivlighan III, D. Martin	2023	Identity salience: An intersectional approach to understanding multicultural processes and outcomes in psychotherapy	Journal of Counseling Psychology	70	5	477-485	<p>A growing body of research has demonstrated the importance of therapists' multicultural orientation (MCO), namely, their cultural humility (CH), cultural comfort, and cultural missed opportunities, on treatment processes and outcomes (Davis et al., 2018). However, to date, few research has attempted to identify client factors that may moderate the relationship between therapists' MCO and therapeutic processes and outcomes. Informed by Yakushko et al.'s (2009) identity salience model, this study seeks to advance the MCO literature by examining the saliency of clients' cultural identities, therapists' MCO, and improvement in therapy. Data for this study consisted</p>

							<p>of 193 individuals who had received at least five sessions of psychotherapy in the last 6 months and responded to an online survey about their experience in therapy. Moderated polynomial regression and response surface analysis was used to examine if the relationship between therapists' MCO and clients' perceived improvement in psychotherapy differed as a function of the salience of clients' first and second most important cultural identities. The results indicated that when clients report only one highly salient cultural identity and perceive their therapist high in cultural humility, they report high levels of improvement. In contrast, when clients reported two highly salient identities, cultural humility and improvement in therapy were not significantly related. Anderson, Katrina; Wickramariyaratne, Tushara; Blair, Annaliese	2018	A feasibility study of group-based cognitive behaviour therapy for older adults in residential care	Clinical Psychologist	22	2	192-202	<p>Objective This study examined the feasibility of providing older adults living in residential aged care with group-based cognitive behavioural therapy (CBT) for depression and anxiety. Method Eighteen participants with subclinical to mild anxiety and/or depression were divided equally into a treatment group and a control group, with treatment consisting of a manualised CBT program for older adults with depression and anxiety. The residents who participated in the group program provided an accurate representation of 'real-world' residential aged care facilities (RACF) populations; many with comorbid physical problems, mild cognitive impairment and functional decline, and a mean age of almost 80 years. Results The residents showed that not only could they successfully engage in psychotherapy, they were able to experience the benefits such as building their skills and resilience, receiving validation and emotional</p>

							support from their fellow residents and fostering friendships and social networks. Encouragingly, the treatment group also showed fewer depressive symptoms post-treatment. Conclusions Group-based psychotherapy should continue to be explored as a strategy to promote good mental health in RACFs, with further studies focusing on the feasibility of recruiting and treating clinical populations in this setting.
Anderson, Timothy; Crowley, Maryellen J.; Binder, Jeffrey L.; Heckman, Bernadette D.; Patterson, Candace L.	2017	Does the supervisor's teaching style influence the supervisee's learning prescribed techniques?	Psychotherapy research : journal of the Society for Psychotherapy Research	27	5	549-557	<p>OBJECTIVES: This study examined the directive and non-directive supervisors' instructional styles, supervisees' interactive communications within supervision sessions as well as the relative success of supervisees' learning to apply specific techniques within psychotherapy.</p> <p>METHOD: The developers of Time-Limited Dynamic Psychotherapy (TLDP) provided the supervised training for 16 therapists as part of the "Vanderbilt II" psychotherapy project. Supervision sessions were rated for supervisors' adherence to TLDP content. Both supervisors and supervisee were rated for classroom interactive behaviors of "initiation" speech (e.g., introducing ideas) and "responsive" speech (e.g., amplifying the other speaker's topic). The third therapy session was targeted for discussion within supervision. Therapy sessions immediately before and after supervision were rated on TLDP adherence. RESULTS: One of the supervisors (Supervisor A) was found to use an instructional style of relatively more initiation-based speech, whereas the other (Supervisor B) used more response-based speech. Technical adherence for supervisees of Supervisor A was significantly higher than those assigned to Supervisor B. Supervisees' initiation-based speech during supervision predicted less use of TLDP techniques in the therapy session after supervision. Supervisors' interactive style</p>

							was not associated with therapy adherence. CONCLUSIONS: Relatively more directive and structured supervision may influence the acquisition and use of manual-prescribed therapy techniques.
Anderson, Timothy; McClintock, Andrew S.; McCarrick, Shannon S.; Heckman, Timothy G.; Heckman, Bernadette D.; Markowitz, John C.; Sutton, Mark	2018	Working Alliance, Interpersonal Problems, and Depressive Symptoms in Tele-Interpersonal Psychotherapy for HIV-infected Rural Persons: Evidence for Indirect Effects	Journal of clinical psychology	74	3	286–303	<p>OBJECTIVE</p> <p>Interpersonal psychotherapy (IPT) has demonstrated efficacy for the treatment of depression, yet little is known about its therapeutic mechanisms. As a specific treatment, IPT has been shown to directly reduce depressive symptoms, although it is unclear whether these reductions occur via interpersonal changes. Within IPT, the potential role of the working alliance, a common factor, as a predictor of depression and interpersonal changes is also unclear.</p> <p>METHOD</p> <p>Participants were 147 depressed persons living with HIV in rural communities of 28 U.S. states enrolled in a randomized clinical trial. Seventy-five patients received up to 9 sessions of telephone-administered IPT (tele-IPT) plus standard care and 72 patients received standard care only. Two models were tested; one included treatment condition (tele-IPT vs. control) and another included the working alliance as independent variables.</p> <p>RESULTS</p> <p>The first model found an indirect effect whereby tele-IPT reduced depression via decreased social avoidance. There was a direct effect between tele-IPT and reduced depression. In the second model, the working alliance influenced depressive symptom relief via reductions in social avoidance. Both goal and task working alliance subscales were indirectly associated with reductions in depressive symptoms, also through reductions in social avoidance. There were no direct effects involving the</p>

							<p>working alliance. Tele-IPT's influence on depressive symptom reduction was primarily through a direct effect, whereas the influence of working alliance depression was almost entirely via an indirect effect through interpersonal problems.</p> <p>CONCLUSION</p> <p>Study findings have implications for IPT when intervening with depressed rural people living with HIV/AIDS over the telephone.</p>
Anderson, Timothy; Stone, Suzannah J.; Angus, Lynne; Weibel, David T.	2022	Double trouble: Therapists with low facilitative interpersonal skills and without training have low in-session experiential processes	Psychotherapy research : journal of the Society for Psychotherapy Research	32	1	78-90	<p>Objectives: This study examined the combined effect of therapist Facilitative Interpersonal Skills (FIS) and Training Status on experiential processes within therapy sessions. In this randomized trial of FIS and Training Status, we predicted that in-session experiential processes would be highest for the high FIS and trained therapist group and lowest for the low FIS and untrained therapists. Methods: Forty-five clients were selected from 2,713 undergraduates using a screening and clinical interview procedure. Twenty-three therapists were selected for their level of FIS (high vs. low) and Training (trainee vs. untrained) and each were assigned two clients for seven sessions each. Two different coder teams independently rated experiencing and narrative process from the third therapy session and computer analysis identified affect words from transcripts. Results: FIS×Training Status significantly interacted on the set of experiential process measures. Relative to all others, therapists who were in the low FIS / no training group had lower experiencing and reflexive content, but higher external content. Conclusions: The findings highlight the importance of therapist characteristics within therapy sessions. Therapists without training and with low interpersonal</p>

							skills have sessions that are nearly devoid of content that focuses on client experiential processes and emotion.
Andorfer, Ute; Musalek, Michael	2017	Wenn ich nur aufhren knnte ... Zur Phnomenologie, Diagnostik und Therapie der Kaufsucht	Psychotherapie im Dialog	18	1	70–74	Es wird informiert ber Phnomenologie, Diagnostik und Therapie der Kaufsucht. Andreas, Sylke; Gablonski, Thorsten- Christian; Tschacher, Wolfgang; Gebhardt, Albrecht; Rabung, Sven; Schulz, Holger; Kadur, Jennifer	2023	Long-term psychodynamic psychotherapy in a face-to-face versus videoconferenci ng setting: A single case study	Journal of clinical psychology	79	2	277–295	OBJECTIVE Due to the coronavirus pandemic and crisis, psychotherapists around the world were forced to switch to video- or tele-based treatments overnight. To date, only a few studies on the effectiveness of video-based psychodynamic psychotherapy via the Internet exist. Therefore, the goal of the present study was to examine symptom improvement, therapeutic relationship, nonverbal synchrony processes, and intersession processes within a systematic single case design and compare face-to-face to video-based approaches in long-term psychodynamic-oriented psychotherapy. METHODS We examined 85 sessions of a client with major depression whose psychodynamic psychotherapy changed from a face-to-face setting to a video-based setting. Video recordings were analyzed using motion

							<p>energy analysis, and nonverbal synchrony was computed using a surrogate synchrony approach. Time series analyses were performed to analyze changes in symptom severity, therapeutic relationship, and intersession processes.</p> <p>RESULTS</p> <p>The results showed that symptom severity improved descriptively, but not significantly, across the entire course of psychotherapy. There were significant differences, however, in the therapeutic relationship, intersession experiences, and synchronous behavior between the face-to-face and video-based settings.</p> <p>CONCLUSION</p> <p>The results indicate that the presented methodology is well situated to investigate the question whether psychodynamic psychotherapy in video-based setting works in the same way as in a face-to-face setting.</p>
<p>Andreasson, Kate; Krogh, Jesper; Wenneberg, Christina; Jessen, Helle K. L.; Krakauer, Kristine; Gluud, Christian; Thomsen, Rasmus R.; Randers, Lasse; Nordentoft, Merete</p>	2016	<p>EFFECTIVENESS OF DIALECTICAL BEHAVIOR THERAPY VERSUS COLLABORATIVE ASSESSMENT AND MANAGEMENT OF SUICIDALITY TREATMENT FOR REDUCTION OF SELF-HARM IN ADULTS WITH</p>	<p>Depression and anxiety</p>	33	6	520–530	<p>BACKGROUND</p> <p>Many psychological treatments have shown effect on reducing self-harm in adults with borderline personality disorder. There is a need of brief psychotherapeutic treatment alternative for suicide prevention in specialized outpatient clinics.</p> <p>METHODS/DESIGN</p> <p>The DiaS trial was designed as a pragmatic single-center, two-armed, parallel-group observer-blinded, randomized clinical superiority trial. The participants had at least two criteria from the borderline personality disorder diagnosis and a recent suicide attempt (within a month). The participants were offered 16 weeks of dialectical behavior therapy (DBT) versus up to 16 weeks of collaborative assessment and management of suicidality (CAMS) treatment. The primary composite outcome was the</p>

		BORDERLINE PERSONALITY TRAITS AND DISORDER-A RANDOMIZED OBSERVER-BLINDED CLINICAL TRIAL				<p>number of participants with a new self-harm (nonsuicidal self-injury [NSSI] or suicide attempt) at week 28 from baseline. Other exploratory outcomes were: severity of borderline symptoms, depressive symptoms, hopelessness, suicide ideation, and self-esteem.</p> <p>RESULTS</p> <p>At 28 weeks, the number of participants with new self-harm in the DBT group was 21 of 57 (36.8%) versus 12 of 51 (23.5%) in the CAMS treatment (OR: 1.90; 95% CI: 0.80-4.40; P = .14). When assessing the effect of DBT versus CAMS treatment on the individual components of the primary outcome, we observed no significant differences in the number of NSSI (OR: 1.60; 95% CI: 0.70-3.90; P = .31) or number of attempted suicides (OR: 2.24; 95% CI: 0.80-7.50; P = .12).</p> <p>CONCLUSION</p> <p>In adults with borderline personality traits and disorder and a recent suicide attempt, DBT does not seem superior compared with CAMS for reduction of number of self-harm or suicide attempts. However, further randomized clinical trials may be needed.</p>
Andrews III, Arthur R.; Walker, Jesse; Bernard, Donte L.; Adams, Zachary; Arellano, Michael de; Danielson, Carla Kmetz		Clinical diversity in a randomized trial that explicitly sought racial/ethnic diversity in its sample: Baseline comparisons in a treatment of youth substance use	Psychological Trauma: Theory, Research, Practice, and Policy	15	Suppl 1	<p>Objective: For more than two decades, federal agencies have sought to address a persistent lack of inclusion of Black, Latinx, Asian, and indigenous peoples in randomized controlled trials (RCTs), often with an underlying hypothesis that such efforts will increase diversity across clinically-relevant dimensions. We examined racial/ethnic and clinical diversity, including racial/ethnic differences in prior service access and symptom dimensions, in an RCT focusing on trauma-related mental health and substance use among adolescents. Method: Participants were 140 adolescents in an RCT of Reducing Risk through Family Therapy.</p>

		and posttraumatic stress				Recruitment followed several recommendations for enhancing diversity. Structured interviews examined trauma exposure, posttraumatic stress disorder (PTSD) and depression symptoms, substance use, service utilization, and demographics. Results: Non-Latinx (NL) Black youth were more likely to receive mental health services for the first time and have greater trauma exposure, but less likely to report symptoms of depression (ps p p > .05). Conclusion: Results suggest that efforts to expand racial/ethnic diversity in an RCT of combined substance use and trauma-focused mental health may also expand other clinical dimensions. Many of these differences reflect multiple dimensions of racism experienced by NL Black families that clinicians must attend to. (PsycInfo Database Record (c) 2023 APA, all rights reserved)	
Andrews, Paul W.; Maslej, Marta M.; Thomson, J. Anderson [JR]; Hollon, Steven D.	2020	Disordered doctors or rational rats? Testing adaptationist and disorder hypotheses for melancholic depression and their relevance for clinical psychology	Clinical psychology review	82		101927	Most clinicians view depression as a painful disorder in which motivation to pursue adaptive goals is lacking and cognition is impaired. An alternative hypothesis-grounded in a common evolutionary approach-suggests that depression is inherently motivational and evolved to motivate avoidant learning of harmful situations. Testing these hypotheses requires a clear definition of "disorder". Wakefield's harmful dysfunction evolution-based definition proposes that all unambiguous cases of disorder involve a malfunctioning adaptation. These hypotheses-functional adaptation and malfunctioning adaptation-are mutually exclusive and require a common research strategy. One must identify and map out the relevant adaptation-characterized by a high degree of non-random organization and coordination for promoting a function-which will eventually result in a conceptual blueprint of where and how the adaptation can

							malfunction. Using inescapable shock in rats and physicians' emotional responses to medical errors to provide context, we show how the symptoms of melancholic depression exhibit signs of adaptation for motivating a time-consuming, attentionally-demanding, energetically-expensive avoidant learning style after experiencing a harmful event. We discuss how this adaptationist approach may provide insight into spontaneous remission and the effects of psychotherapies and antidepressant medications.
Angus, Lynne E.; Boritz, Tali; Bryntwick, Emily; Carpenter, Naomi; Macaulay, Christianne; Khattra, Jasmine	2017	The Narrative-Emotion Process Coding System 2.0: A multi-methodological approach to identifying and assessing narrative-emotion process markers in psychotherapy	Psychotherapy research : journal of the Society for Psychotherapy Research	27	3	253-269	OBJECTIVE: Recent studies suggest that it is not simply the expression of emotion or emotional arousal in session that is important, but rather it is the reflective processing of emergent, adaptive emotions, arising in the context of personal storytelling and/or Emotion-Focused Therapy (EFT) interventions, that is associated with change. METHOD: To enhance narrative-emotion integration specifically in EFT, Angus and Greenberg originally identified a set of eight clinically derived narrative-emotion integration markers were originally identified for the implementation of process-guiding therapeutic responses. Further evaluation and testing by the Angus Narrative-Emotion Marker Lab resulted in the identification of 10 empirically validated Narrative-Emotion Process (N-EP) markers that are included in the Narrative-Emotion Process Coding System Version 2.0 (NEPCS 2.0). RESULTS: Based on empirical research findings, individual markers are clustered into Problem (e.g., stuckness in repetitive story patterns, over-controlled or dysregulated emotion, lack of reflectivity), Transition (e.g., reflective, access to adaptive emotions and new emotional plotlines, heightened narrative and emotion integration), and Change (e.g., new story

						<p>outcomes and self-narrative discovery, and co-construction and re-conceptualization) subgroups. To date, research using the NEPCS 2.0 has investigated the proportion and pattern of narrative-emotion markers in Emotion-Focused, Client-Centered, and Cognitive Therapy for Major Depression, Motivational Interviewing plus Cognitive Behavioral Therapy for Generalized Anxiety Disorder, and EFT for Complex Trauma. Results have consistently identified significantly higher proportions of N-EP Transition and Change markers, and productive shifts, in mid- and late phase sessions, for clients who achieved recovery by treatment termination.</p> <p>CONCLUSIONS: Recovery is consistently associated with client storytelling that is emotionally engaged, reflective, and evidencing new story outcomes and self-narrative change. Implications for future research, practice and training are discussed.</p>	
Anjum, Gulnaz; Aziz, Mudassar; Hamid, Hadar Khasrow	2023	Life and mental health in limbo of the Ukraine war: How can helpers assist civilians, asylum seekers and refugees affected by the war?	Frontiers in psychology	14		1129299	<p>The terror spread by the war disrupts lives and severs families, leaving individuals and communities devastated. People are left to fend for themselves on multiple levels, especially psychologically. It is well documented that war adversely affects non-combatant civilians, both physically and psychologically. However, how the war puts civilians' lives in a limbo is an under-researched area. This paper focuses on three aspects: (1) how the mental health and well-being of Ukrainian civilians, asylum seekers, and refugees are affected by the war caused limbo; (2) what factors affect this process of being stuck in the limbo of war; and (3) how psychologists and helpers in the war-ridden and host countries can provide meaningful support. Based on the authors' own practical work with Ukrainian civilians, refugees, and professional helpers during the war, this</p>

						<p>paper provides an overview of multi-level factors that impact human psyches in a war, and possible ways to help those who are living in the war limbo. In this research and experiential learning-based review, we offer some helpful strategies, action plans, and resources for the helpers including psychologists, counselors, volunteers, and relief workers. We emphasize that the effects of war are neither linear nor equal for all civilians and refugees. Some will recover and return to a routine life while others will experience panic attacks, trauma, depression, and even PTSD, which can also surface much later and can prolong over the years. Hence, we provide experience-based ways of dealing with short-term and prolonged trauma of living with war and post-traumatic stress disorder (PTSD). Mental health professionals and other helpers in Ukraine and in host countries can use these helping strategies and resources to provide effective support for Ukrainians and for war refugees in general.</p>
<p>Ansar, Nadia; Hjeltnes, Aslak; Stige, Signe Hjelen; Binder, Per-Einar; Stiegler, Jan Reidar</p>	<p>2021</p>	<p>Parenthood-Lost and Found: Exploring Parents' Experiences of Receiving a Program in Emotion Focused Skills Training</p>	<p>Frontiers in psychology</p>	<p>12</p>	<p>559188</p>	<p>BACKGROUND: Parents play a crucial role in the development, maintenance, and deterioration of child difficulties. Emotion focused skills training (EFST) targets parents' capacity to provide their child with emotion-oriented skills in order to promote good child mental health. Few qualitative studies have specifically investigated parents' experiences of receiving such programs. OBJECTIVE: This study aimed to explore how parents experience working with their own and their child's emotions undergoing a short-term program in EFST; in particular, changes in their experience of being a parent and in everyday life are reported. METHOD: Semi-structured in-depth qualitative interviews were conducted with 14 parents who had completed a short-term EFST program (2-day group training and 6 h of</p>

						<p>supervision). Interview transcripts were analyzed using a reflexive thematic analysis approach. RESULTS: A total of 14 parents (40% men, four couples, Mage = 39.5, SD = 4.4) participated in the study. Our analysis resulted in the following three themes: (1) "Coming home" as a parent, with the following subthemes: (a) New ways of being with their child and (b) Parents' painful inner world; (2) Reclaiming parenthood-applying new tools and learning in challenging situations; and (3) This is us-changing the heart of the story. The first theme was related to the descriptions of the changes that emerged in parents' inner lives, the second revolved around the employment of their skills intuitively and creatively based on what was required by the challenging situations, and the third theme referred to new discoveries on family dynamics. CONCLUSION: Parents' experiences of having wisdom and calmness inside them (being) and doing parenting differently, as well as the changed perspectives of the family (living), resonate with the theoretical ground of emotion-focused therapy (EFT). The findings also indicate that therapists should be aware of potential parental distress when working in view of changing unpleasant emotions in such skill-based programs.</p>
<p>Ansar, Nadia; Nissen Lie, Helene A.; Stiegler, Jan Reidar</p>	<p>2023</p>	<p>The effects of emotion-focused skills training on parental mental health, emotion regulation and self-efficacy: Mediating processes</p>	<p>Psychotherapy research : journal of the Society for Psychotherapy Research</p>		<p>1-20</p>	<p>Objective: Emotion-Focused Skills Training (EFST) is a short-term parental intervention based on humanistic principles. While studies have demonstrated the efficacy of EFST in alleviating child mental health symptoms, the mechanisms by which this happens is less clear. The present study investigated whether program participation led to improvements in the parents' own mental health, emotion regulation, and self-efficacy, and compared two versions of EFST: one experiential involving evocative techniques, and one psychoeducational involving</p>

		between parents and children					<p>didactic teaching of skills. Further, this study investigated whether improvements in parent outcomes mediated the effects on children's mental health. All parents received 2-days group training and 6 h of individual supervision. Methods: 313 parents (M(age) = 40.5, 75.1% mothers) of 236 children (ages 6-13, 60.6% boys) with mental health difficulties within the clinical range and their teachers (N = 113, 82% female) were included. Participants were assessed at baseline, post-intervention, and 4-, 8- and 12-months follow-up. Results: Multilevel analysis showed significant improvements over time on all parental outcomes with large effects ($d(\text{range})0.6-1.1$, $ps < .001$), with fathers benefitting more in terms of emotion regulation and self-efficacy ($ps < .05$). Significant differences were found between conditions on parental mental health and self-efficacy (all $p's > .05$). Cross-lagged panel models showed indirect effects of child symptoms at post-intervention on all parental outcomes at 12-months follow-up ($\beta(\text{range})0.30-0.59$, $ps < .05$). Bidirectional associations were observed between children's mental health symptoms and parental self-efficacy ($\beta(\text{range})0.13-0.30$, $ps < .05$). Conclusion: This study provides support for the effect of EFST on parent outcomes and the reciprocal relationship between the mental health of children's and their parents. Trial registration: ClinicalTrials.gov identifier: NCT03807336.</p>
Ansar, Nadia; Nissen Lie, Helene A.; Zahl-Olsen, Rune; Bertelsen, Thomas B.; Elliott, Robert;	2022	Efficacy of Emotion-Focused Parenting Programs for Children's Internalizing	Journal of clinical child and adolescent psychology : the official journal for the Society of Clinical Child	51	6	923-939	<p>OBJECTIVE: Emotion-Focused Skills Training (EFST) is a 12-week parental program based on Emotion-Focused Therapy, developed to improve children and adolescents' mental health problems. METHODS: In a randomized clinical dismantling study, including parents of 236 children and adolescents (ages 6-13, M(age) 8.9, 60.6% boys, 95.8% Caucasian) with externalizing and/or</p>

Stiegler, Jan Reidar		and Externalizing Symptoms: A Randomized Clinical Study	and Adolescent Psychology, American Psychological Association, Division 53				internalizing problems within clinical range, we examined the efficacy of two versions of EFST: one experiential condition (n = 120) involving emotionally evocative techniques and two-chair interventions, and one psychoeducational only condition (n = 116) involving didactic teaching of emotion skills. Both groups received a 2-day group training and 6 hours of individual supervision. Outcomes were parent- and teacher-reported symptoms at baseline, posttreatment, and 4-, 8-, and 12-month follow-up. Analyses were conducted using multilevel growth curve modeling and Bayesian post hoc analysis. RESULTS: EFST showed efficacy in reducing parent-reported externalizing (b = -1.72, p < .001, d = 1.0) and internalizing (b = -1.71, p < .001, d = 0.9) symptoms, and teacher-reported externalizing (b = -.96, p < .001, d = 0.4), but not internalizing (b = -.13, p > .05, d = 0.2) symptoms. Multilevel analyses showed nonsignificant differences between conditions (all p's > .05), although a Bayesian longitudinal sensitivity analysis indicated a better outcome for the experiential condition. CONCLUSION: EFST showed efficacy in symptom reduction for children and adolescents with internalizing and externalizing symptoms. Outcomes were maintained over 12 months for both conditions, supporting EFST as a transdiagnostic parental approach for early intervention.
Anthony Friel, Joseph	2016	What Detoxifies Shame in Integrative Psychotherapy? an Interpretative Phenomenological Analysis	Brit J Psychotherapy (British Journal of Psychotherapy)	32	4	532-546	

Antonelli, Mary T.; Grace, Pamela J.; Boltz, Marie	2020	Mutual caregiving: Living meaningfully as an older couple	International journal of older people nursing	15	4	e12340	<p>BACKGROUND: More older couples are living independently while managing chronic health conditions. Though research is replete in identifying the influence of spouse's behaviours on each other's health, there is little known of the specific factors underlying the older couples' relational processes to explain this dynamic. Knowledge development is needed to provide a grounding for interventions to address such influences to improve health and well-being. AIM: The aim of this study was to advance the understanding of older couples' experiences of living with chronic health conditions to gain insights into the potential benefits of 'being a couple' to manage behavioural health and life adjustments. METHOD: A hermeneutic-dialectic phenomenology design based on Newman's theory of Health as Expanding Consciousness was used. Fourteen older couples were jointly interviewed. The interviews were non-structured and designed to capture their experience as a couple. RESULTS: Three themes emerged (a) living meaningfully through mutual caregiving, (b) a pattern of spousal movement facilitating change and (c) co-creating as an older couple to move forward. CONCLUSION: The study supports reframing older couple's care as a 'dyad of care'. This approach provides an opportunity to leverage the couples' mutuality to support health management as a couple. A motivation to action process between the spouses appeared to enable mutual caregiving, a reliance of each spouse on the another for identity, socialisation, health and daily living, which facilitated an evolving understanding of their lives and its meaning. IMPLICATIONS FOR PRACTICE: Mutual caregiving should be acknowledged as a significant relational dynamic</p>

Applebaum, A. J.; Buda, K. L.; Schofield, E.; Farberov, M.; Teitelbaum, N. D.; Evans, K.; Cowens-Alvarado, R.; Cannady, R. S.	2018	Exploring the cancer caregiver's journey through web-based Meaning-Centered Psychotherapy	Psycho-oncology	27	3	847-856	<p>OBJECTIVE Psychosocial interventions are historically underutilized by cancer caregivers, but support programs delivered flexibly over the Internet address multiple barriers to care. We adapted Meaning-Centered Psychotherapy for cancer caregivers, an in-person psychotherapeutic intervention intended to augment caregivers' sense of meaning and purpose and ameliorate burden, for delivery in a self-administered web-based program, the Care for the Cancer Caregiver (CCC) Workshop. The present study evaluated the feasibility, acceptability, and preliminary effects of this program.</p> <p>METHODS Eighty-four caregivers were randomized to the CCC Workshop or waitlist control arm. Quantitative assessments of meaning, burden, anxiety, depression, benefit finding, and spiritual well-being were conducted preintervention (T1), within 2-weeks postintervention (T2), and 2- to 3-month follow-up (T3). In-depth semistructured interviews were conducted with a subset of participants.</p> <p>RESULTS Forty-two caregivers were randomized to the CCC Workshop. Attrition was moderate at T2 and T3, with caregiver burden and bereavement as key causes of drop-</p>

						<p>out. At T2 and T3, some observed mean change scores and effect sizes were consistent with hypothesized trends (eg, meaning in caregiving, benefit finding, and depressive symptomatology), though no pre-post significant differences emerged between groups. However, a longitudinal mixed-effects model found significant differential increases in benefit finding in favor of the CCC arm.</p> <p>CONCLUSIONS</p> <p>The CCC Workshop was feasible and acceptable. Based on effect sizes reported here, a larger study will likely establish the efficacy of the CCC Workshop, which has the potential to address unmet needs of caregivers who underutilize in-person supportive care services.</p>
<p>Arkedis, Jean; Creighton, Jessica; Dixit, Akshay; Fung, Archon; Kosack, Stephen; Levy, Dan; Tolmie, Courtney</p>	2021	<p>Can transparency and accountability programs improve health? Experimental evidence from Indonesia and Tanzania</p>	World development	142	105369	<p>We assess the impact of a transparency and accountability program designed to improve maternal and newborn health (MNH) outcomes in Indonesia and Tanzania. Co-designed with local partner organizations to be community-led and non-prescriptive, the program sought to encourage community participation to address local barriers in access to high quality care for pregnant women and infants. We evaluate the impact of this program through randomized controlled trials (RCTs), involving 100 treatment and 100 control communities in each country. We find that on average, this program did not have a statistically significant impact on the use or content of maternal and newborn health services, nor on perceptions of civic efficacy or civic participation among recent mothers in the communities where it was offered. These findings hold in both countries and in a set of prespecified subgroups. To identify reasons for the lack of impacts, we use a mixed-method approach combining interviews, observations, surveys, focus groups, and</p>

							ethnographic studies that together provide an in-depth assessment of the complex causal paths linking participation in the program to improvements in MNH outcomes. Although participation in program meetings was substantial and sustained in most communities, and most attempted at least some of what they had planned, only a minority achieved tangible improvements, and fewer still saw more than one such success. In our assessment, the main explanation for the lack of impact is that few communities were able to traverse the complex causal paths from planning actions to accomplishing tangible improvements in their access to quality health care.
Arkema, Carroll E.	2018	Reflections on a case of spirituality in clinical practice	Spirituality in Clinical Practice	5	1	64–73	In this Reflections article, the author introduces and shares a poem he wrote about his 10-year therapeutic journey with a patient; discusses some of the psychodynamics and transference of the Case; and concludes by demonstrating the congruence and mutual illumination between 2 articles he has recently read and his work as presented in his poem—which he wrote 3 years prior to reading these articles. The author shows how excerpts from these articles and the author’s poem about his work give a taste of the reciprocity between certain conceptualizations of spirituality and the author’s clinical practice in this Case. Aronow, Harriet; Fila, Susan; Martinez, Bibiana; Sosna, Todd	2018	Depression and Coleman Care Transitions Intervention	Social work in health care	57	9	750–761	The Coleman Care Transitions Intervention (CTI) is a "Patient Activation Model." Depression can be a barrier to activation and may challenge CTI. This study addressed whether CTI coaches modified the intervention for older adults who screened positive for depression. Over 4,500 clients in a Centers for Medicare and Medicaid Services demonstration completed screening for depression with

							the PHQ-9; one in five screened positive (score = 9+). Our findings suggest that coaches modified CTI and played a more directive role for clients who screened positive for depression, resulting in similar 30-day readmission rates among patients who screened positive for depression risk and those who did not. That finding stands in contrast to the widely reported higher readmission rates among people screening positive for depression.
Arora, Saachi; Bhatia, Sangeeta	2022	Gender differences in factors that facilitate successful therapeutic progress and outcome: A pilot study	Couns and Psychother Res (Counselling and Psychotherapy Research)	22	4	1030–1040	Abstract The current study aims to explore gender differences in factors that facilitate successful therapeutic progress and outcome in the process of psychotherapy. The study was conducted in order to facilitate gender-sensitive psychotherapy. In order to ascertain the objectives, the sample was collected from individuals who have either experienced or are experiencing psychotherapy as clients. In total, 20 females and 20 males were selected for participation in the study. The data were collected through an online mode. Informed consent was obtained from all clients. The tools used in the study were Session Rating Scale and Session Impacts Scale. The tools were used to assess the factors that determine therapeutic progress and outcomes. Information obtained on these tools was recorded and assessed through quantitative data analysis. Participants were also assessed qualitatively by asking them to describe any major events or important impacts that occurred as a result of psychotherapy. Qualitative responses were then recorded and analysed using content analysis in order to explore the subjective experiences of participants which contributed to their recovery. The findings indicated that males and females equally value the importance of therapeutic alliance between the therapist and client, and agreement on goals

							and methods. Males and females perceive task and relationship-oriented factors as helpful in therapy. The relationship factors include being supported and encouraged in therapy, and feeling validated and understood by the therapist. The task-oriented factors include tools used in therapy, definition of problems and setting therapeutic goals. Males tend to be more sensitive towards factors that inhibit the therapeutic process in comparison with females. Males experience the feeling of ?something missing? in therapy sessions more than females. Overall, the findings of this study enhance the understanding of factors that aid recovery in the psychotherapy process for males and females.
Arrais, Paulo Sérgio Dourado; Fernandes, Maria Eneida Porto; Pizzol, Tatiane da Silva Dal; Ramos, Luiz Roberto; Mengue, Sotero Serrate; Luiza, Vera Lucia; Tavares, Noemia Urruth Leão; Farias, Mareni Rocha; Oliveira, Maria Auxiliadora; Bertoldi, Andréa Dâmaso	2016	Prevalence of self-medication in Brazil and associated factors	Revista de saude publica	50	su ppl 2	13s	OBJECTIVE: To analyze the prevalence and associated factors regarding the use of medicines by self-medication in Brazil. METHODS: This cross-sectional population-based study was conducted using data from the PNAUM (National Survey on Access, Use and Promotion of Rational Use of Medicines), collected between September 2013 and February 2014 by interviews at the homes of the respondents. All people who reported using any medicines not prescribed by a doctor or dentist were classified as self-medication practitioners. Crude and adjusted prevalence ratios (Poisson regression) and their respective 95% confidence intervals were calculated in order to investigate the factors associated with the use of self-medication by medicines. The independent variables were: sociodemographic characteristics, health conditions and access to and use of health services. In addition, the most commonly consumed medicines by self-medication were individually identified. RESULTS: The self-medication prevalence in Brazil was 16.1% (95%CI 15.0-17.5), with it being highest in the Northeast

						<p>region (23.8%; 95%CI 21.6-26.2). Following the adjusted analysis, self-medication was observed to be associated with females, inhabitants from the North, Northeast and Midwest regions and individuals that have had one, or two or more chronic diseases. Analgesics and muscle relaxants were the therapeutic groups most used for self-medication, with dipyron being the most consumed medicines. In general, most of the medicines used for self-medication were classified as non-prescriptive (65.5%). CONCLUSIONS: Self-medication is common practice in Brazil and mainly involves the use of non-prescription medicines; therefore, the users of such should be made aware of the possible risks. OBJETIVO: Analisar a prevalência e os fatores associados à utilização de medicamentos por automedicação no Brasil. MÉTODOS: Este estudo transversal de base populacional foi realizado com dados da Pesquisa Nacional de Acesso, Utilização e Promoção do Uso Racional de medicamentos (PNAUM), coletados de setembro de 2013 a fevereiro de 2014, por meio de entrevistas em domicílio. Todas as pessoas que referiram usar qualquer medicamento sem prescrição por médico ou dentista foram classificadas como praticantes de automedicação. Foram calculadas razões de prevalência bruta e ajustada (regressão de Poisson) e seus respectivos intervalos de confiança de 95% na investigação dos fatores associados ao consumo de medicamentos por automedicação. As variáveis independentes foram: aspectos sociodemográficos, de condições de saúde e de acesso e utilização de serviços de saúde. Adicionalmente, foram identificados os medicamentos mais consumidos por automedicação. RESULTADOS: A prevalência da automedicação no Brasil</p>
--	--	--	--	--	--	---

							<p>foi de 16,1% (IC95% 15,0-17,5), sendo maior na região Nordeste (23,8%; IC95% 21,6-26,2). Após análise ajustada, automedicação mostrou-se associada a ser do sexo feminino, pertencer às faixas etárias 10-19 anos, 20-29 anos, 40-59 anos e 60 anos ou mais, residir na região Norte, Nordeste ou Centro-Oeste, e ter uma ou duas ou mais doenças crônicas. Os analgésicos e os relaxantes musculares foram os grupos terapêuticos mais utilizados por automedicação, sendo a dipirona o fármaco mais consumido. No geral, a maioria dos medicamentos usados por automedicação foram classificados como isentos de prescrição (65,5%). CONCLUSÕES: A automedicação é prática corrente no Brasil e envolve, principalmente, o uso de medicamentos isentos de prescrição, devendo os usuários ficarem atentos aos seus possíveis riscos.</p>
Asarnow, Joan Rosenbaum; Tompson, Martha C.; Klomhaus, Alexandra M.; Babeva, Kalina; Langer, David A.; Sugar, Catherine A.	2020	Randomized controlled trial of family- focused treatment for child depression compared to individual psychotherapy: one-year outcomes	Journal of child psychology and psychiatry, and allied disciplines	61	6	662-671	<p>OBJECTIVE Childhood-onset depression is associated with increased risk of recurrent depression and high morbidity extending into adolescence and adulthood. This multisite randomized controlled trial evaluated two active psychosocial treatments for childhood depression: family-focused treatment for childhood depression (FFT-CD) and individual supportive psychotherapy (IP). Aims were to describe effects through 52 weeks postrandomization on measures of depression, functioning, nondepressive symptoms, and harm events.</p> <p>METHODS Children meeting criteria for depressive disorders (N = 134) were randomly assigned to 15 sessions of FFT-CD or IP and evaluated at mid-treatment for depressive symptoms and fully at roughly 16 weeks (after acute treatment), 32 weeks, and 52 weeks/one year. See</p>

							<p>clinicaltrials.gov: NCT01159041.</p> <p>RESULTS</p> <p>Analyses using generalized linear mixed models confirmed the previously reported FFT-CD advantage on rates of acute depression response ($\geq 50\%$ Children's Depression Rating Scale reduction). Improvements in depression and other outcomes were most rapid during the acute treatment period, and leveled off between weeks 16 and 52, with a corresponding attenuation of observed group differences, although both groups showed improved depression and functioning over 52 weeks. Survival analyses indicated that most children recovered from their index depressive episodes by week 52: estimated 76% FFT-CD, 77% IP. However, by the week 52 assessment, one FFT-CD child and six IP children had suffered recurrent depressive episodes. Four children attempted suicide, all in the IP group. Other indicators of possible harm were relatively evenly distributed across groups.</p> <p>CONCLUSIONS</p> <p>Results indicate a quicker depression response in FFT-CD and hint at greater protection from recurrence and suicide attempts. However, outcomes were similar for both active treatments by week 52/one year. Although community care received after acute treatment may have influenced results, findings suggest the value of a more extended/chronic disease model that includes monitoring and guidance regarding optimal interventions when signs of depression-risk emerge.</p>
Aschenbrenner, Steffen; Bossert, Magdalena	2021	Ein individualisierter Psychotherapie	Zeitschrift für Neuropsychologie	32	2	49–60	Im Rahmen einer Übersichtsarbeit wird der aktuelle Forschungsstand zu neurokognitiven Symptomen bei Depression dargestellt und eine daraus abgeleitete Anpassung des psychotherapeutischen Vorgehens

		ansatz fr depressive Patient_innen mit kognitiven Symptomen					beschrieben. Bei einer Vielzahl von Patientinnen und Patienten mit Depression treten kognitive Beeintrchtigungen auf, die auch nach Remission der akuten Psychopathologie fortbestehen. Die kognitiven Symptome beeinflussen mageblich das psychosoziale Funktionsniveau und den Erfolg psychotherapeutischer Interventionen. Sie sind ein Prdiktor fr das Wiederauftreten der Erkrankung. Vor dem Hintergrund wird ein Konzept fr die Anpassung des psychotherapeutischen Vorgehens vorgeschlagen, das die Bereiche (1) Diagnostik und Identifikation, (2) Strukturierung, (3) Kompensation, (4) Erfahrungsorientierung, (5) aktivierende Stimulation und (6) restitutives Training umfasst.
Aschieri, Filippo; Vetere, Carlo	2020	Using the Rorschach as a group intervention to promote the understanding of adolescents by staff members in inpatient residential programs	Rorschachiana		21 51- 20 6X(Ele ctr oni c), 11 92- 56 04(Pri nt)	120-143	Mental health professionals working in adolescent residential treatment facilities face various challenges in delivering effective treatment to their patients. Establishing therapeutic alliance is often regarded as particularly daunting. Adolescents' acting-out behaviors, emotional dysregulation, and difficulty in trusting adults can trigger strong reactions in mental health professionals. These reactions may increase the risk that mental health professionals respond to adolescents' behaviors in similarly unmodulated ways and become involved in a reciprocal pathological process. The Rorschach test can provide vivid imagery and response content that depicts the subjective dilemmas adolescents are struggling with during their recovery in the treatment center. In this paper we show how to use Rorschach imagery to allow the mental health professionals working in adolescent inpatient treatment centers to understand their patients and increase empathy in response to adolescents' troubling behaviors.

							We illustrate this procedure through the case of an adolescent patient who engaged in severely disruptive acting-out behaviors with the treating staff. Even though the staff were considering terminating his treatment in the facility as the only viable option, they instead found new empathy and a way to work with him after discussion of his Rorschach led by the inpatient center psychologist. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Ascone, Leonie; Sundag, Johanna; Schlier, Björn; Lincoln, Tania M.	2017	Feasibility and Effects of a Brief Compassion-Focused Imagery Intervention in Psychotic Patients with Paranoid Ideation: A Randomized Experimental Pilot Study	Clinical psychology & psychotherapy	24	2	348-358	UNLABELLED Paranoia is characterized by a lack of perceived social safeness and associated negative affect. Low self-esteem, negative self-concepts and negative emotions have been shown to contribute to paranoid symptom formation. Thus, interventions focusing on affiliation and positive affect might be particularly helpful for patients with paranoia. The present study experimentally tested the effect of a one-session, brief compassion-focused imagery derived from Compassion-Focused Therapy (Gilbert,) versus a control imagery condition in a repeated measures randomized design. A negative affective state was induced via in-sensu exposure to a recent distressful social situation in order to provide a minimum level of threat-related arousal to be down-regulated by the interventions thereafter. The sample consisted of psychotic patients with paranoid ideation (N = 51) who were randomly assigned to one of the experimental conditions. Effects on postulated causal mechanisms, i.e., self-relating (self-reassurance, self-compassion, self-criticism), and affect (self-reported affective states, skin conductance levels) as well as on state paranoia, were tested. Subjective benefit and appraisals of the intervention were explored. There were

						<p>no specific intervention effects on negative self-relating, negative affect and skin-conductance or on paranoia. However, compassion-focused imagery had significant effects on self-reassurance and happiness. Explorative analyses revealed that the majority of the participants appraised the intervention in a positive manner, indicating good acceptance. The intervention showed an effect on some of the postulated mechanisms but not on others, which might have been because of its brevity. Further investigation of interventions targeting affiliation for people with paranoid experiences appears worthwhile. Copyright © 2016 John Wiley & Sons, Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Affiliative imagery work is feasible and appraised positively in psychotic patients. Brief compassion focused imagery increased feelings of happiness and reassurance but did not improve negative self-relating, negative affect or paranoia. Further investigation is warranted to identify which patients benefit most from affiliative imagery.</p>
Asfar, T.; Livingstone-Banks, J.; Ward, K. D.; Eissenberg, T.; Oluwole, O.; Bursac, Z.; Ghaddar, T.; Maziak, W.	2023	Interventions for waterpipe smoking cessation	Cochrane Database of Systematic Reviews	6(6): CD005549. doi: 10.1002/14651858.CD005549.pub4	6	<p>Abstract - Background While cigarette smoking has declined globally, waterpipe smoking is rising, especially among youth. The impact of this rise is amplified by mounting evidence of its addictive and harmful nature. Waterpipe smoking is influenced by multiple factors, including appealing flavors, marketing, use in social settings, and misperceptions that waterpipe is less harmful or addictive than cigarettes. People who use waterpipes are interested in quitting, but are often unsuccessful at doing so on their own. Therefore, developing and testing waterpipe cessation interventions to help people quit was identified as a priority for global tobacco control efforts. Objectives To evaluate the</p>

						<p>effectiveness of tobacco cessation interventions for people who smoke waterpipes. Search methods We searched the Cochrane Tobacco Addiction Review Group Specialized Register from database inception to 29 July 2022, using variant terms and spellings ('waterpipe' or 'narghile' or 'arghile' or 'shisha' or 'goza' or 'narkeela' or 'hookah' or 'hubble bubble'). We searched for trials, published or unpublished, in any language. Selection criteria We sought randomized controlled trials (RCTs), quasi-RCTs, or cluster-RCTs of any smoking cessation interventions for people who use waterpipes, of any age or gender. In order to be included, studies had to measure waterpipe abstinence at a three-month follow-up or longer. Data collection and analysis We used standard Cochrane methods. Our primary outcome was abstinence from waterpipe use at least three months after baseline. We also collected data on adverse events. Individual study effects and pooled effects were summarized as risk ratios (RR) and 95% confidence intervals (95% CI), using Mantel-Haenszel random-effects models to combine studies, where appropriate. We assessed statistical heterogeneity with the I² statistic. We summarized secondary outcomes narratively. We used the five GRADE considerations (risk of bias, inconsistency of effect, imprecision, indirectness, and publication bias) to assess the certainty of the body of evidence for our primary outcome in four categories high, moderate, low, or very low. Main results This review included nine studies, involving 2841 participants. All studies were conducted in adults, and were carried out in Iran, Vietnam, Syria, Lebanon, Egypt, Pakistan, and the USA. Studies were conducted in several settings, including colleges/universities, community healthcare</p>
--	--	--	--	--	--	--

						<p>centers, tuberculosis hospitals, and cancer treatment centers, while two studies tested e-health interventions (online web-based educational intervention, text message intervention). Overall, we judged three studies to be at low risk of bias, and six studies at high risk of bias. We pooled data from five studies (1030 participants) that tested intensive face-to-face behavioral interventions compared with brief behavioral intervention (e.g. one behavioral counseling session), usual care (e.g. self-help materials), or no intervention. In our meta-analysis, we included people who used waterpipe exclusively, or with another form of tobacco. Overall, we found low-certainty evidence of a benefit of behavioral support for waterpipe abstinence (RR 3.19 95% CI 2.17 to 4.69; I² = 41%; 5 studies, N = 1030). We downgraded the evidence because of imprecision and risk of bias. We pooled data from two studies (N = 662 participants) that tested varenicline combined with behavioral intervention compared with placebo combined with behavioral intervention. Although the point estimate favored varenicline, 95% CIs were imprecise, and incorporated the potential for no difference and lower quit rates in the varenicline groups, as well as a benefit as large as that found in cigarette smoking cessation (RR 1.24, 95% CI 0.69 to 2.24; I² = 0%; 2 studies, N = 662; low-certainty evidence). We downgraded the evidence because of imprecision. We found no clear evidence of a difference in the number of participants experiencing adverse events (RR 0.98, 95% CI 0.67 to 1.44; I² = 31%; 2 studies, N = 662). The studies did not report serious adverse events. One study tested the efficacy of seven weeks of bupropion therapy combined with behavioral intervention. There was no clear evidence of benefit for waterpipe cessation when</p>
--	--	--	--	--	--	---

						<p>compared with behavioral support alone (RR 0.77, 95% CI 0.42 to 1.41; 1 study, N = 121; very low-certainty evidence), or with self-help (RR 1.94, 95% CI 0.94 to 4.00; 1 study, N = 86; very low-certainty evidence). Two studies tested e-health interventions. One study reported higher waterpipe quit rates among participants randomized to either a tailored mobile phone or untailored mobile phone intervention compared with those randomized to no intervention (RR 1.48, 95% CI 1.07 to 2.05; 2 studies, N = 319; very low-certainty evidence). Another study reported higher waterpipe abstinence rates following an intensive online educational intervention compared with a brief online educational intervention (RR 1.86, 95% CI 1.08 to 3.21; 1 study, N = 70; very low-certainty evidence).</p> <p>Authors' conclusions We found low-certainty evidence that behavioral waterpipe cessation interventions can increase waterpipe quit rates among waterpipe smokers. We found insufficient evidence to assess whether varenicline or bupropion increased waterpipe abstinence; available evidence is compatible with effect sizes similar to those seen for cigarette smoking cessation. Given e-health interventions' potential reach and effectiveness for waterpipe cessation, trials with large samples and long follow-up periods are needed. Future studies should use biochemical validation of abstinence to prevent the risk of detection bias. Finally, there has been limited attention given to high-risk groups for waterpipe smoking, such as youth, young adults, pregnant women, and dual or poly tobacco users. These groups would benefit from targeted studies.</p> <p>Plain language summary Can users of waterpipes be helped to quit through smoking cessation interventions? Key messages • Limited evidence showed that behavioral support might be helpful for quitting</p>
--	--	--	--	--	--	---

						<p>waterpipe use. [I] [SEP] • There was not enough evidence to evaluate the effect of varenicline, bupropion, or e-health interventions for quitting waterpipe use. [I] [SEP] • In all cases, further studies may change our conclusions. Further large and well-designed trials on behavioral and pharmacological waterpipe cessation interventions are needed. [I] [SEP] • Given the potential reach and effectiveness of e-health interventions to help quit waterpipe smoking, trials with large samples and long follow-up periods are needed. [I] [SEP] • Reporting more details about the behavioral strategies used in study interventions would help identify vital components in waterpipe interventions. What is a waterpipe? Waterpipes are devices used for smoking tobacco. As used today, the waterpipe (also known as hookah, shisha, or narghile) consists of a head (where tobacco is placed), a body, a water base, and a hose that ends with a mouthpiece. Burning charcoal pieces are usually placed on top of a pierced aluminum foil that covers the tobacco-filled head, which allows the charcoal-heated air to pass through the tobacco, while the holes in the bottom of the head allow the smoke to pass down through the waterpipe stem. The lower part of the stem is underwater, causing smoke to bubble through, on its way via the hose and mouth tip to the smoker. The mouth tip is usually covered with a disposable mouthpiece for individual users. How is waterpipe addiction treated? Forms of support to help people quit waterpipe smoking are similar to those that target other forms of tobacco use. These include behavioral support, quit-smoking medicines, and combinations of the two. Why did we do this Cochrane Review? Waterpipe smoking has increased dramatically, becoming a global public health problem, especially</p>
--	--	--	--	--	--	--

						<p>among young people. Current evidence suggests that waterpipe smoking is as addictive as cigarettes, and that users will experience similar risks to their health as cigarette smokers. Therefore, developing and testing waterpipe-specific quitting interventions is important. What did we do? We included trials of any interventions to help waterpipe smokers quit smoking. They could be of any age or gender. We measured whether participants had stopped using a waterpipe at three months after the intervention or longer. We included interventions that were directed at individuals or groups of people. What did we find? We found nine studies that tested interventions to help waterpipe smokers to quit. Among these, five studies tested behavioral support; two studies tested a quit-smoking medicine, called varenicline; one study tested a quit-smoking medicine called bupropion; and two studies tested e-health support delivered over the internet or mobile phone. What are the main results of our review? We have low-quality evidence that face-to-face behavioral support helps more people quit waterpipe smoking than no support. We are uncertain about the effect of bupropion, varenicline, and e-health interventions because of the limited evidence. What are the limitations of the evidence? Results are based on data from just a few studies. Six of the nine studies had design issues that may affect how much we trust the results. In addition, the included behavioral interventions differed from one another, and were not always well described. This means that our results may change when more studies become available. How up-to-date is this evidence? This search for evidence was performed in July 2022.</p>

<p>Ashe, Maureen C.; Azim, Farah Tabassum; Ariza-Vega, Patrocinio; Burns, Jane; Clemson, Lindy; Grover, Sanya; Hoppmann, Christiane A.; Langford, Dolores; Fleig, Lena; Burton, Elissa</p>	<p>2022</p>	<p>Determinants of implementing reablement into research or practice: A concept mapping study</p>	<p>Physiotherapy Research International, 2022</p>			<p>Purpose: Reablement is a health and social model of care gaining international prominence. It is included in some publicly funded healthcare systems in Australia, Canada, United Kingdom, Norway, Sweden and other European countries. To advance reablement research and practice, we aimed to synthesize expert opinion on opportunities and challenges to delivering care with this model. Methods: We invited authors of reablement publications and other experts from the field to take part in a three-step online concept mapping exercise: (i) brainstorming statements based on a focus prompt; followed by (ii) sorting and (iii) rating statements. We invited 63 participants, of whom 19 participants generated 114 statements. Two authors reviewed each statement independently then met three times to determine one main idea/statement and removed unrelated or duplicate ideas. The research team used concept mapping software and online and email discussion to generate clusters or groups of determinants. Results: There were 58 statements for sorting and rating; 11 and 12 participants completed the sorting and rating steps, respectively. The five clusters were person and caregiver elements for participation; key reablement components for success; reablement content and delivery; organizational factors; and provider beliefs and training. Statements rated as both highly important and feasible to implement into practice were generally captured under the domains of goal setting and pursuit and person-centred care. Conclusion: These results generate hypotheses for future research and practice in reablement for older adults.</p>

Ashing, Kimlin Tam; George, Marshalee	2020	Exploring the efficacy of a paraprofessional delivered telephonic psychoeducational intervention on emotional well-being in African American breast cancer survivors	Supportive care in cancer : official journal of the Multinational Association of Supportive Care in Cancer	28	3	1163–1171	<p>PURPOSE African American breast cancer survivors (AABCS) are underserved in medical and psychosocial care despite greater disease burden. We evaluated the effectiveness of a telephonic psycho-educational intervention trial on improving emotional well-being (EWB) in a sample of AABCS.</p> <p>METHODS Secondary data analyses with 40 AABCS who reported elevated distress were randomly assigned to the intervention or control group. We used Wilcoxon signed rank tests to measure pre- to post-intervention score changes in individual EWB items (FACT-G). Independent t tests compared changes in mean scores between the intervention and control groups.</p> <p>RESULTS Overall emotional well-being, as well as emotions pertaining to sadness, coping, and nervousness, showed some improvements as a result of the intervention. Changes in the subscale total score and all except one subscale item had clinically meaningful effect sizes ($d \geq 0.35$). Statistically significant between-group differences in mean score changes were observed.</p> <p>CONCLUSIONS Our results and approach advance supportive care interventions by illuminating the benefits and limitations of a paraprofessional delivered, licensed professional supervised psycho-educational intervention. Additionally, as emotional well-being is multifaceted, the individual item analysis approach used in this study provides insight into specific areas of improvement and vulnerability within the emotional well-being domain of health-related quality of life (HRQOL). Our findings can facilitate the</p>

							development of culturally responsive and patient-centered survivorship care, psychosocial-oncology interventions and care-tailored to the emotional well-being and unmet needs of medically vulnerable and underserved patients.
Assmann, Nele; Schramm, Elisabeth; Kriston, Levente; Hautzinger, Martin; Härter, Martin; Schweiger, Ulrich; Klein, Jan Philipp	2018	Moderating effect of comorbid anxiety disorders on treatment outcome in a randomized controlled psychotherapy trial in early-onset persistently depressed outpatients	Depression and anxiety	35	10	1001–1008	<p>BACKGROUND Persistent depressive disorder (PDD) is associated with high rates of comorbid psychiatric disorders, mostly anxiety disorders (ADs). Comorbid AD was found to be associated with poorer treatment outcome in PDD patients. The effect of comorbid AD on disorder-specific treatment for PDD (Cognitive Behavioral Analysis System of Psychotherapy [CBASP]) has not been studied yet.</p> <p>METHODS We analyzed whether the presence of a comorbid AD was moderating the effectiveness of disorder-specific (CBASP) versus nonspecific psychotherapy (supportive therapy [SP]) on depressive symptoms (24-item Hamilton Rating Scale for Depression [HRSD-24]) in a sample of unmedicated early-onset PDD outpatients (N = 268). Secondary outcomes were response and remission of depressive symptoms and the extent of interpersonal problems (Inventory of Interpersonal Problems [IIP-64]).</p> <p>RESULTS The superiority of CBASP over SP was significantly stronger in PDD patients with comorbid AD compared to patients without AD (in HRSD-24 and IIP-64). There was no significant moderation for remission or response of depressive symptoms.</p> <p>DISCUSSION Our hypothesis of a moderating effect of comorbid AD was confirmed. The main limitation might be the exclusion criteria of our sample limiting the</p>

							<p>generalizability. The major strength is the systematic analysis of the effect of AD in treating early-onset PDD with high quality of psychotherapy in both arms of this trial.</p> <p>CONCLUSION</p> <p>Patients suffering from PDD comorbid with AD might experience greater benefit when they are treated with specific as opposed to unspecific therapy. Analyzing subgroups of patients with PDD seems worthwhile to improve treatment effectiveness even within disorder-specific treatment programmes.</p>
Atasuntseva, Anaid A.; Basile, Krista; La Prade, Rebecca; Wilberding, Nicole; Friedberg, Rebecca J.; Wister, Andrea S.; Friedberg, Robert D.	2020	Public perceptions of behavioral health care and psychotherapy for youth: Promotion and product dimensions	Professional Psychology: Research and Practice	51	5	507-516	<p>Increasing utilization of behavioral health services for distressed youth and their families is a compelling public health imperative. Public perceptions and attitudes toward child therapy impact behavioral health care utilization rates. This study investigated adults' attitudes toward child psychotherapy using a new survey method and instrument. A real-world intercept survey design where data is collected from individuals while they are entering or exiting common locations such as malls and retail stores was employed. Respondents were asked to complete the Attitudes and Perceptions of Child Psychotherapy Scale, which is an 18-item consumer-centric instrument. One hundred adult individuals completed the survey focusing on the perceived value of services/providers (product dimension) and the types of providers preferred by the public (promotion dimension). The findings yielded several compelling results. Pediatricians, psychologists, and psychiatrists were seen as the most trustworthy and effective clinical providers. Further, pediatricians were viewed as the most necessary health care provider for children. Reputation, utilization of treatments that work, and being referred by a trusted</p>

							source were the top reasons for choosing a behavioral health provider. Finally, clinical improvement and children's relationship with the provider were the most highly rated factors to consider when receiving treatment. Implications are discussed in terms of increasing mental health literacy and developing materials that engage potential consumers of pediatric behavioral health care. A-Tjak, Jacqueline G. L.; Morina, Nexhmedin; Topper, Maurice; Emmelkamp, Paul M. G.	2021	One year follow-up and mediation in cognitive behavioral therapy and acceptance and commitment therapy for adult depression	BMC psychiatry	21	1	41	BACKGROUND: Existing therapies for depression are effective, but many patients fail to recover or relapse. To improve care for patients, more research into the effectiveness and working mechanisms of treatments is needed. We examined the long-term efficacy of Cognitive Behavioral Therapy (CBT) and Acceptance and Commitment Therapy (ACT) for Major Depressive Disorder (MDD), testing the hypothesis that CBT outperforms ACT and that both therapies work through their designated mechanisms of change. METHODS: We conducted a randomized controlled trial with 82 patients suffering from MDD. Data were collected before, during and after treatment, and at 12-month follow-up, assessing symptoms of depression, quality of life, dysfunctional attitudes, decentering, and experiential avoidance. RESULTS: Patients in both conditions reported significant and large reductions of depressive symptoms ($d = -1.26$ to -1.60) and improvement in quality of life ($d = 0.91$ to -1.28) 12 months following treatment. Our findings indicated no significant differences between the two interventions. Dysfunctional attitudes and decentering mediated treatment effects of depressive symptoms in both CBT and ACT, whereas experiential avoidance mediated treatment effects in ACT only.

							CONCLUSIONS: Our results indicate that CBT is not more effective in treating depression than ACT. Both treatments seem to work through changes in dysfunctional attitudes and decentering, even though the treatments differ substantially. Change in experiential avoidance as an underlying mechanism seems to be an ACT-specific process. Further research is needed to investigate whether ACT and CBT may work differently for different groups of patients with depression. TRIAL REGISTRATION: clinicaltrials.gov; NCT01517503 . Registered 25 January 2012 - Retrospectively registered.
Auckenthaler, Anna	2014	Von der Ehetherapie zur Psychotherapie mit Paaren. Paartherapie nach 1968	Psychotherapie im Dialog	15	4	26–29	Ziele der neuen Paartherapie werden denen der frühen Ehetherapie gegenübergestellt und Hintergründe für den Richtungswechsel aufgezeigt. Nach einer Darstellung der Grundlagen früher Paartherapie (Modifikation von Kommunikation und Interaktionsmustern basierend auf einem Einheitsmodell von Partnerschaft) wird das neue Selbstverständnis der Paartherapie (Förderung von Akzeptanz mit einem Fokus auf emotionalen Ressourcen) erläutert. Diese Veränderungen werden auf empirische Befunde zur Wirkung von Paartherapie und Einflüsse gesellschaftlicher Entwicklungen zurückgeführt.
Austin, Jillian E.; Doering, Jennifer J.; Davies, W. Hobart	2018	Using technology to teach parents to create a safe infant sleep space	Clinical Practice in Pediatric Psychology	6	3	211–222	The American Academy of Pediatrics (AAP) published Recommendations for a Safe Infant Sleeping Environment; however, parents still report frequent use of dangerous infant sleep practices. An online computer program was developed and piloted to investigate whether parents could be taught to create safe sleep environments using online training. Computerized safe sleep environments created by parents of children 0 to 23 months were assessed for compliance with the AAP Sleep Recommendations. Using a pre- and posttest design, the present study investigated the effectiveness

							of online instructions (adapted standard of care) and a computerized behavioral skills training package, which included instructions, modeling, rehearsal, and feedback. Additional pre- and posttests assessed parents' ability to identify sleep risks in 3 pictures to assess generalization of skills learned. Overall, participants demonstrated significant improvements from pre- to posttest across both treatment conditions on the creation of a safe sleep environment and on the free response identification of risks in 3 sleep environments. Performance did not significantly differ between the treatment groups. Results suggest considerable promise for technology-aided approaches in training parents to create a safe sleep environment. Auszra, Lars; Herrmann, Imke	2021	Emotionsfokussierte Therapie	krper - tanz - bewegung	9	1	40-50	Die Emotionsfokussierte Therapie (Greenberg 2006; Auszra et al. 2017) ist ein evidenzbasiertes Verfahren, das die Arbeit mit Emotionen in den Mittelpunkt stellt. Sie integriert humanistisch-erlebensorientierte Verfahren mit der psychologischen Emotionsforschung, den affektiven Neurowissenschaften und der Psychotherapieprozessforschung zu einer eigenen Therapie- und Veränderungstheorie. Die Verbesserung der emotionalen Verarbeitung bei Patienten, welche im Kern die Utilisierung von adaptivem und die Transformation von maladaptivem emotionalem Erleben beinhaltet, wird als zentraler Motor für therapeutische Veränderung gesehen.
Auszra, Lars; Herrmann, Imke R.; Greenberg, Leslie S.	2017	Emotionsfokussierte Therapie. Ein Praxismanual					Es wird eine fundierte und praxisnahe Einführung in die Emotionsfokussierte Therapie (EFT) gegeben. Emotionen stehen in der EFT als Wegweiser und Motor im Mittelpunkt des Therapieprozesses. Sie helfen zu erkennen, was besonders bedeutsam für einen Patienten ist und sind

						<p>zudem eine wichtige Quelle für Veränderungen. Aus ihrem bewussten Erleben heraus kann neues Erleben, Fühlen, Denken und Verhalten entstehen. Hilfreiche Prinzipien und Strategien, um wirkungsvoll mit den Emotionen von Patienten zu arbeiten und Emotionen als Ressource im Veränderungsprozess zu nutzen, werden vermittelt.</p> <p>Theoretische Grundlagen und wichtige Forschungsergebnisse zur EFT werden ebenso behandelt wie die Förderung von Veränderungsprozessen. Die therapeutische Beziehungsgestaltung und allgemeine Prinzipien therapeutischen Handelns werden beschrieben. Anhand von Beispielen und Transkripten authentischer Therapiesitzungen wird erläutert, wie die Prinzipien und Methoden der EFT, wie etwa Focusing und Stuhl-Dialoge, in der Praxis konkret angewendet werden können. Zudem wird auf die Anwendung der EFT bei unterschiedlichen Strukturbildern sowie den Umgang mit typischen Schwierigkeiten in der Therapie eingegangen. - Inhalt: (1) Theoretische Grundlagen (Emotionen; emotionale Schemata; dialektischer Konstruktivismus). (2) Theorie therapeutischer Veränderung (klinische Emotionstheorie; Theorie der Entstehung emotionaler Schwierigkeiten; Theorie emotionaler Verarbeitung bzw. Veränderung; Prozess therapeutischer Veränderung). (3) Therapeutisches Vorgehen (Haltung des Therapeuten und Gestaltung der therapeutischen Beziehung; Wahrnehmungsfertigkeiten; Interventionsfertigkeiten; Verarbeiten; Fallformulierung; Phasen der Therapie). (4) Marker und Aufgaben (Empathie; empathisches Bestimmen bei Verletzlichkeit des Patienten; Focusing bei einem unklaren oder abwesenden Felt Sense; systematisches evokatives Erschließen bei problematischen Reaktionen; Zwei-Stuhl-Dialog bei Konflikten zwischen Selbstanteilen;</p>

Auszra, Lars; Herrmann, Imke R.; grosse Holtforth, Martin	2017	Emotionsfokussierte Therapie (EFT)					
Auszra, Lars; Sutter, Marielle; Herrmann, Imke	2017	Emotionsfokussierte Therapie - emotionales Erleben fördern	Psychotherapie	22	1	52-66	Ein Überblick über die Theorie der Emotionsfokussierten Therapie (EFT) sowie ihrer wichtigsten Prinzipien der Beziehungsgestaltung und des therapeutischen Handelns wird gegeben. Es wird berichtet, wie die EFT emotionales Erleben in der Weise fördert, dass adaptive Emotionen aufgebaut und maladaptive Emotionen verändert werden. Zunächst wird Greenbergs Emotionstheorie dargestellt, aus der Interventionen abgeleitet werden. Nach der Beschreibung der besonderen Gestaltung der therapeutischen Beziehung werden konkrete Transaktionen in der Therapiesitzung mit den Schritten des Gewährwerdens von Emotionen, des Gefühlsausdrucks, des Gefühlsregulierens, des Reflektierens und schließlich der Transformation bzw. Veränderung des Gefühls dargestellt. Die hierzu erforderlichen therapeutischen Fähigkeiten und konkreten Interventionen werden diskutiert. Schließlich wird das Vorgehen der EFT anhand eines klinischen Beispiels veranschaulicht.

Avants, S. Kelly; Margolin, Arthur; Singer, Jerome L.	1993	Psychological interventions and research in the oncology setting: An integrative framework	Psychotherapy	30	1	1-10	
Avdibegović, Esmina; Brkić, Maja; Hasanović, Mevludin	2021	Integrating the Concept of Creative Psychopharmacotherapy and Group Psychotherapy in Clinical Practice	Psychiatria Danubina	33	Suppl 4	1144-1150	Modern psychiatric treatment is largely dictated by national and international guidelines rested on evidence-based data, including psychopharmacotherapy and psychotherapy. An alternative to the rigid application of official guidelines and criterion for the standards of treatment in psychiatric practice is the concept of creative psychopharmacotherapy. It is a concept based on the integration of different approaches to a person as whole, mental disorders and their treatment into person-centered clinical practice. In this sense, group psychotherapy and creative psychopharmacotherapy today are part of the overall integrative efforts in psychiatry. Neuroscientific discoveries suggest that they share similar neural pathways that lead to changes in brain function and symptoms relief. Various integrative elements make group psychotherapy and psychopharmacotherapy in combination more effective and efficient. The integration of the concept of creative psychopharmacotherapy and group psychotherapy into everyday clinical practice can improve treatment options as well as clinical practice by creating opportunities for research and development of new modalities of overall treatment.

Babl, Anna; Berger, Thomas; Gómez Penedo, Juan Martín; grosse Holtforth, Martin; Caspar, Franz; Eubanks, Catherine F.	2022	Disaggregating between- and within-patient effects of ruptures and resolutions on the therapeutic alliance and symptom severity	Psychotherapy		19 39- 15 36(Ele ctr oni c), 00 33- 32 04(Pri nt)	567-571	The therapeutic alliance is considered a robust predictor of psychotherapy outcome. Ruptures and resolutions in the alliance have been the focus of recent alliance literature. Most previous studies investigated their between-patient effects. We used hierarchical linear models to disaggregate the between- and within-patient effects of ruptures on the alliance from patient- and therapist perspective and symptom severity. Further, the moderating effects of rupture resolutions were analyzed. The sample consisted of 56 patients diagnosed with depressive or anxiety disorders who received 25 ± 3 sessions of integrative cognitive behavioral therapy in the outpatient setting. The observer-rated rupture resolution rating system was applied to all 1st, 8th, 16th and 24th therapy sessions. The alliance quality and symptom

							severity were assessed using self-report questionnaires after these four sessions. Results showed that a higher intensity of ruptures across treatment was associated with lower alliance ratings from both patient- and therapist perspectives during treatment. After sessions with more intense confrontation ruptures, both reported a weaker alliance. Rupture resolutions significantly moderated the withdrawal rupture effect on the alliance. The results provide meaningful practical implications for therapist feedback and training. They further underline the importance of using appropriate statistical analyses to the data structure and nature of psychotherapy to better understand the role of the alliance, rupture, and repair during therapy. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Babl, Anna; Gómez Penedo, Juan Martín; Berger, Thomas; Schneider, Noemi; Sachse, Rainer; Kramer, Ueli	2023	Change processes in psychotherapy for patients presenting with histrionic personality disorder	Clinical psychology & psychotherapy	30	1	64–72	<p>OBJECTIVE: Histrionic personality disorder (HPD) with a lifetime prevalence rate of 1.8% is an under-researched psychiatric diagnosis. The present study therefore aimed to investigate both the processes and outcomes of psychotherapy for HPD in a non-controlled study.</p> <p>METHODS: A total of 159 patients diagnosed with HPD were recruited and received clarification-oriented psychotherapy. Sessions 15, 20, and 25 were video-recorded and analysed using the Process-Content-Relationship Scale. Therapy outcome was assessed with symptom measures at intake and discharge. Hierarchical linear modelling was applied to estimate the changes in the psychotherapeutic outcome and associations with patient and therapist process developments.</p> <p>RESULTS: Improvements in relationship processes of patients and therapists were systematically related to outcome while only partial relationships were found on the levels of process and content.</p> <p>CONCLUSION: The present study</p>

							represents the first systematic insight into core changes in patients with HPD undergoing psychotherapy.
Babl, Anna; grosse Holtforth, Martin; Heer, Sara; Lin, Mu; Stähli, Annabarbara; Holstein, Dominique; Belz, Martina; Egenolf, Yvonne; Frischknecht, Eveline; Ramseyer, Fabian; Regli, Daniel; Schmied, Emma; Flückiger, Christoph; Brodbeck, Jeannette; Berger, Thomas; Caspar, Franz	2016	Psychotherapy integration under scrutiny: investigating the impact of integrating emotion-focused components into a CBT-based approach: a study protocol of a randomized controlled trial	BMC psychiatry	16	1	423	BACKGROUND: This currently recruiting randomized controlled trial investigates the effects of integrating components of Emotion-Focused Therapy (EFT) into Psychological Therapy (PT), an integrative form of cognitive-behavioral therapy in a manner that is directly mirroring common integrative practice in the sense of assimilative integration. Aims of the study are to understand how both, an existing therapy approach as well as the elements to be integrated, are affected by the integration and to clarify the role of emotional processing as a mediator of therapy outcome. METHODS: A total of 130 adults with a diagnosed unipolar depressive, anxiety or adjustment disorder (seeking treatment at a psychotherapy outpatient clinic) are randomized to either treatment as usual (PT) with integrated emotion-focused components (TAU + EFT) or PT (TAU). Primary outcome variables are psychopathology and symptom severity at the end of therapy and at follow up; secondary outcome variables are interpersonal problems, psychological wellbeing, quality of life, attainment of individual therapy goals, and emotional competency. Furthermore, process variables such as the quality of the therapeutic relationship are studied as well as aptitude-treatment interactions. Variables are assessed at baseline, after 8 and 16 sessions, at the end of therapy, after 25 ± 3 sessions, and at 6, 12 and 36 month follow-up. Underlying mechanisms of change are investigated. Statistical analyses will be conducted using the appropriate multilevel approaches, mainly two-level regression and growth analysis. DISCUSSION: The results of this study will indicate whether the integration of emotion-focused

							elements into treatment as usual increases the effectiveness of Psychological Therapy. If advantages are found, which may be limited to particular variables or subgroups of patients, recommendations for a systematic integration, and caveats if also disadvantages are detected, can be formulated. On a more abstract level, a cognitive behavioral (represented by PT) and humanistic/experiential (represented by EFT) approach will be integrated. It must be emphasized that mimicking common practice in the development and continued education of psychotherapists, EFT is not integrated as a whole, but only elements of EFT that are considered particularly important, and can be trained in an 8-day training plus supervision of therapies. TRIAL REGISTRATION: ClinicalTrials.gov, NCT02822443 , 22 June 2016, retrospectively registered.

Meret; Berger, Thomas; Caspar, Franz							
Backhaus, Ulrike	2019	Verlusterleben und Trauerprozess - menschliche, personzentrierte und psychotherapeutische Perspektiven	Psychologie in sterreich	39	3	160-167	Der folgende Text stellt Trauer als natrlichen und gesunden Prozess dar, mit dem wir Menschen auf Verluste reagieren, die unser Leben zwangslufig begleiten. Theorien zum Trauerprozess werden ebenso vorgestellt wie der personzentrierte Umgang mit Menschen nach Verlust in Therapie und Beratung. Auerdem wird auf komplizierte Trauerverlufe eingegangen, die eine Minderheit der Trauernden betreffen und im psychotherapeutischen Kontext immer wieder anzutreffen sind.
Baez, Shelby; Hoch, Matthew C.; Hoch, Johanna M.	2018	Evaluation of Cognitive Behavioral Interventions and Psychoeducation Implemented by Rehabilitation Specialists to Treat Fear-Avoidance Beliefs in Patients With Low Back Pain: A Systematic Review	Archives of physical medicine and rehabilitation	99	11	2287-2298	OBJECTIVES: To systematically locate, critically appraise, and synthesize the available evidence regarding the effectiveness of cognitive behavioral therapies (CBTs) and psychoeducation that can be implemented by rehabilitation specialists to treat fear-avoidance beliefs in patients with acute, subacute, and chronic low back pain (LBP). DATA SOURCES: Electronic databases (CINAHL, PubMed, Psychology and Behavior Sciences Collection, SPORTDiscus, PsycINFO) were searched from inception to September 2017. STUDY SELECTION: Assessment of methodological quality was completed using the Physiotherapy Evidence Database (PEDro) scale. The Strength of Recommendation Taxonomy was used to evaluate the quality of evidence. DATA EXTRACTION: Study sample, subject demographics, CBT and/or psychoeducation intervention details, data collection time points, outcome assessments, statistical analysis, results, and conclusions were extracted from each study. In addition, effect sizes were calculated. DATA SYNTHESIS: Five high-quality studies (PEDro ≥6) were

							included. All included studies evaluated fear-avoidance beliefs. CBTs and psychoeducation strategies designed to target patient-specific fears demonstrated clinically meaningful results, while psychoeducation methodologies were not as effective. CONCLUSIONS: There is inconsistent, patient-oriented evidence (grade B) to support the use of CBTs and/or psychoeducation strategies by rehabilitation specialists to treat fear-avoidance beliefs. Patient-centered and personalized CBTs were most effective to treat these psychosocial factors in patients with LBP when compared with a control treatment.
Bager-Charleson, Sofie	2019	“She was on my side, and grounded me when I needed it.” Research supervision in the field of therapy, based on counsellors’ and psychotherapists’ views on their engagement with research	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	4	358–365	
Bager-Charleson, Sofie; Kasap, Zeynep	2017	Embodied situatedness and emotional entanglement in research – An autoethnographic hybrid inquiry	Scand J Med Sci Sports (Scandinavian Journal of Medicine & Science in Sports)	17	3	190–200	Abstract Background In clinical practice, counsellors and psychotherapists rely heavily on their emotional and embodied responses as part of their data gathering. What happens with this epistemological positioning when we generate knowledge in therapy research? Aim: As therapists? researchers, we are intrigued by what Bondi (2012, Qualitative Inquiry, 19, 9) refers to as a gap

		into the experience of doing data analysis					<p>between therapeutic practice and research. There are many angles to this 'gap?', but we have focused on the how to conceptualise and act on our embodied responses during our data analysis phase, with an interest in the emotional entanglement between researchers and the researched. Materials linguistically, personally and as an underpinning grappling with worldviews in light of the researchers' different epistemic origins. Concluding Discussion Being in a no-mans-land between old and new understandings triggered a sense of loss of theory and challenged temporarily our sense of selves. Bion (1961, Learning from experience. London: Karnac) and Gendlin (1997, A process model. New York: Focusing Institute) are examples of 'frameworks' which helped to welcome the feeling of lost-ness, rather than feeling threatened and overwhelmed. The process reminds of the epistemic positioning we learn to adopt in our therapeutic practice. Gendlin (1997) refers to this kind 'staying with' the 'body-feel' as means of generating new understandings. The purpose of this article has not been to offer a step by-step approach to data analysis, but rather to join Stanley's (2013, Journal of Contemporary Ethnography, 44, 143) 'call for accounts' about what it feels like to do research. Some stages involved excitement, growth, harmony and enrichment, other felt surprisingly unsettling as our own prior understanding expanded. This article only scrapes the surface but might stimulate further discussions around the researcher's use of self at different stages of the process. Therapists are increasingly encouraged to develop research informed practice; this article suggests that our attention also turns to practice informed research, to create platforms for discussions around</p>

Bahr, Christiane	2016	Als alte Frau zu neuer Lebensfreude finden. ber den Psychotherapie prozess mit einer lteren Frau, die ihre Angst bewltigte	Person	20	2	139–150	Der spezifisch weibliche und lnger dauernde Therapieprozess einer hheraltrigen Frau wird geschildert, die ihre Angst und Panikgefhle allmhlich berwindet und schrittweise zu einer neuen Wahrnehmung ihres Seins sowie zu neuer Lebensfreude und Kraft findet. Dabei werden die zusammenfassende Analyse sowie die wissenschaftliche Reflexion dieses mittlerweile erfolgreich abgeschlossenen klientenzentrierten Psychotherapieprozesses dargestellt, welcher im Sinne qualitativer Therapie- und Feldforschung dokumentiert

							wurde. Es wird gezeigt, wie die Klientin zu therapeutischen Wegen der Heilung aus ihrer Angst und zu beglückender Lebensqualität findet, indem sie ihre Rolle als Frau reflektiert, therapeutische Interventionen hilfreich aufgreift und erwägt, Eindrücke in sich nachgeht und normative Erwartungen seitens ihrer Umgebung allmählich durchschaut. Als betagte Ehefrau, pensionierte Geschäftsfrau und vielfache Mutter, Großmutter und Urgroßmutter lernt sie ihre Prioritäten neu zu ordnen und vorhandene soziale Netzwerke zu würdigen sowie hiermit verbundene Möglichkeiten erneut konstruktiv zu nutzen. Beschrieben wird, dass es im Verlauf des gesamten psychotherapeutischen Prozesses dabei aus therapeutischer Sicht immer wieder konkreter Praktiken bedarf, die ihr helfen neue Wege zu suchen und achtsam zu gehen.
Baker, Andrew Z.; Peluso, Paul R.; Freund, Robert; Diaz, Patricia; Ghaness, Amrita	2022	Using dynamical systems mathematical modeling to examine the impact emotional expression on the therapeutic relationship: A demonstration across three psychotherapeutic theoretical approaches	Psychotherapy research : journal of the Society for Psychotherapy Research	32	2	223–237	Objective: The purpose of this paper is to describe an approach to dynamical systems (DS) using a set of differential equations, and how an application of these equations can be used to address a critical element of the therapeutic relationship. Using APA's Three Approaches to Psychotherapy with a Female Client: The Next Generation and Three Approaches to Psychotherapy with a Male Client: The Next Generation videos, DS models were created for each of the six sessions with expert clinicians (Judith Beck, Leslie Greenberg, and Nancy McWilliams) from the three theoretical approaches. Method: A second-by-second observational coding system of the emotional exchanges of the therapists and clients was used as the data for the equations. Results: DS modeling allowed for a side-by-side comparison between the three approaches as well as between the two clients. Examining the graphs created

							by plotting the results of the DS equations (in particular, phase-space portraits) revealed that there were similarities among the three theoretical approaches, and there were notable differences between the two clients. Conclusions: DS modelling can provide researchers and clinicians with a powerful tool to investigate the complex phenomenon that is psychotherapy.
Balbo, Marina; Cavallo, Francesca; Fernandez, Isabel	2019	Integrating EMDR in psychotherapy	Journal of Psychotherapy Integration	29	1	23–31	Eye movement desensitization and reprocessing (EMDR) has significantly contributed to psychotherapy in the last 30 years. Studies support EMDR as effective for posttraumatic stress disorder symptoms. It was also applied to other disorders because it can help resolve and reprocess memories of traumatic experiences that can contribute, as risk, precipitating and predisposing factors to the development of mental disorders. What these disorders have in common is the maladaptive processing of information associated with stressful and pathogenic events. EMDR therapy has given a contribution to psychotherapy as an effective method that can help the innate processing system process all aspects of a traumatic experience. After working with traumatic memories that may be part of the patient's life story, EMDR therapy focuses on current triggers and symptoms and then provides the patient with instruments to deal with future situations that may cause anxiety. While working with this method, it is possible to enhance metacognitive skills and promote a change in dysfunctional emotions, beliefs, and behaviors. These are some common objectives that EMDR therapy shares with most psychotherapy approaches. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Balint, Elisabeth Maria; Daniele,	2023	Heart rate variability	Psychophysiology	60	1	e14150	The bio-psycho-social model highlights intra-individual and inter-individual interactions, including

<p>Viktorija; Langgartner, Dominik; Reber, Stefan O.; Rothermund, Eva; Gündel, Harald; Wietersheim, Jörn von; Buckley, Thomas; Jarczok, Marc N.</p>		<p>predicts outcome of short-term psychotherapy at the workplace</p>				<p>psychotherapy. The processing of these interactions within a person takes place, among others, in the central autonomic network (CAN). The CAN's autonomic output to the periphery can be indexed by heart rate variability (HRV), representing individual adaptive capacity. Further, the CAN influences the hypothalamus-pituitary-adrenal axis with its product cortisol. The aim consisted in investigating HRV and cortisol as well as their relation to symptom course in response to short-term psychotherapy. A single-arm, uncontrolled, explorative study was conducted at an outpatient psychotherapeutic consultation in the workplace offered to employees with mental or psychosomatic complaints. Questionnaires included symptoms of depression, irritation and functional impairment. Circadian profile of HRV and salivary cortisol concentrations collected pre and post short-term psychotherapeutic intervention (4-12 sessions) were assessed. Multilevel-linear mixed regressions were calculated. Out of 29 participants (mean age 42; 72% female), 24% were on sick leave from work. Cortisol concentrations were neither affected by intervention nor by symptom course. The proportion of individuals showing a vagally mediated HRV in the range of the lowest quartile assessed for age- and sex-matched healthy controls was reduced at follow-up (pre 34%, post 22%; $p = .017$). Higher vagally mediated HRV at baseline predicted lower symptom burden at follow-up. Thus, the results support the assumption that HRV reflects the capability of an organism to adapt and recover. Patients with reduced HRV might need additional psychotherapeutic sessions to achieve the same symptom improvements than patients with retained HRV.</p>

Balkhausen, Diana	2023	Möglichkeiten und Grenzen experiencieller Methoden in der psychotherapeutischen Arbeit mit komplex traumatisierten Kindern und Jugendlichen					Möglichkeiten und Grenzen experiencieller Methoden der Psychotherapie bei komplexen Traumafolgestrungen bei Kindern und Jugendlichen werden vorgestellt. Neben den grundlegenden psychotherapeutischen Vorgehensweisen in verschiedenen traumatherapeutischen Anstzen werden die experienciellen Basiskonzepte Haltung, Prozessorientierung, Erlebnisorientierung und Krperorientierung beschrieben.
Ballard, Clive; Orrell, Martin; Sun, Yongzhong; Moniz-Cook, Esme; Stafford, Jane; Whitaker, Rhiannon; Woods, Bob; Corbett, Anne; Banerjee, Sube; Testad, Ingelin; Garrod, Lucy; Khan, Zunera; Woodward-Carlton, Barbara; Wenborn, Jennifer; Fossey, Jane	2017	Impact of antipsychotic review and non-pharmacological intervention on health-related quality of life in people with dementia living in care homes: WHELD-a factorial cluster randomised controlled trial	International journal of geriatric psychiatry	32	10	1094–1103	BACKGROUND: Very few interventional studies have directly examined the impact of treatment approaches on health-related quality of life (HRQL) in people with dementia. This is of particular importance in therapies to address behavioural symptoms, where HRQL is often severely affected. METHODS: Analysis within the WHELD cluster randomised factorial study in 16 UK care homes examining the impact of person-centred care in combination with antipsychotic review, social interaction and exercise interventions. This study analysed impact on HRQL through the DEMQOL-Proxy. RESULTS: Data on HRQL were available for 187 participants. People receiving antipsychotic review showed a significant worsening in two DEMQOL-Proxy domains (negative emotion: $p = 0.02$; appearance: $p = 0.04$). A best-case scenario analysis showed significant worsening for total DEMQOL-Proxy score. Social interaction intervention resulted in a significant benefit to HRQL ($p = 0.04$). There was no deterioration in HRQL in groups receiving both antipsychotic review and social interaction ($p = 0.62$). CONCLUSIONS: This demonstrates an important detrimental impact of discontinuation of antipsychotics in dementia on HRQL, highlighting the need for careful

							review of best practice guidelines regarding antipsychotic use and emphasizing the importance of providing evidence-based non-pharmacological interventions in conjunction with antipsychotic review. Copyright © 2016 John Wiley & Sons, Ltd.
Balogh, Lehel	2023	Meaning-formation and sense of purpose in Morita therapy	Journal of evaluation in clinical practice	29	7	1222–1227	Morita therapy is one of the leading alternative psychotherapeutic approaches that has emerged from Japan and has adapted with notable success to the mores and demands of the Western medical establishment. Although still on the margin, Morita therapy has the potential to offer a viable option for those who seek therapeutic assistance for various neuroses and psychosomatic illnesses that culminate in psychiatric symptoms such as generalized anxiety disorder, obsessive-compulsive disorder, or posttraumatic stress disorder. Diverging considerably from conventional Western psychiatric approaches, Morita therapy has its own modes of conceiving mental illness and offers distinct curative methods that are in some ways akin to the techniques of meaning-centred psychotherapies, but in many other ways are rather different. In this paper, the meaning-formation and the building of a constant sense of purpose in Morita therapy is explored, with a special focus on how these relate to creating a stable psychological framework for the client.
Balser, Kristin; Hollick, Ulrike	2021	Spieltherapie nach Nierentransplantation. Krankheitsbewältigung und Identitätsfindung	Gesprächspsychotherapie und Personenzentrierte Beratung	52	1	19–23	Der Artikel beschreibt die spieltherapeutische Begleitung eines Mädchens nach einer Nierentransplantation. Er zeigt die Möglichkeit auf, durch das therapeutische Spiel Kinder in Phasen, die eine Lebensveränderung bedeuten, in ihrer Identitätsentwicklung und ihrem Selbstkonzept durch das hohe Maß an Symbolisierung und Ausdrucksmöglichkeit zu unterstützen. Der Text ist zugleich ein Plädoyer für die Notwendigkeit der Bearbeitung ihrer

							Krankheitsgeschichte und belastender Erlebnisse in spieltherapeutischer Begleitung fr Kinder mit chronischen Erkrankungen. Elise war zu Beginn der spieltherapeutischen Begleitung 13 Jahre alt und seit einem Monat zum zweiten Mal nierentransplantiert. Eine Psychologin des kindernephrologischen Zentrums fhrte die spieltherapeutische Begleitung Elises im Rahmen der psychosozialen Betreuung der Familie durch.
Bamelis, Lotte L. M.; Arntz, Arnoud; Wetzelaer, Pim; Verdoorn, Ryanne; Evers, Silvia M. A. A.	2015	Economic evaluation of schema therapy and clarification-oriented psychotherapy for personality disorders: a multicenter, randomized controlled trial	The Journal of clinical psychiatry	76	11	e1432-40	<p>PURPOSE To compare from a societal perspective the cost-effectiveness and cost-utility of schema therapy, clarification-oriented psychotherapy, and treatment as usual for patients with avoidant, dependent, obsessive-compulsive, paranoid, histrionic, and/or narcissistic personality disorder.</p> <p>METHOD A multicenter, randomized controlled trial, single-blind parallel design, was conducted between May 2006 and December 2011 in 12 Dutch mental health institutes. Data from 320 patients (diagnosed according to DSM-IV criteria) randomly assigned to schema therapy (n = 145), treatment as usual (n = 134), or clarification-oriented psychotherapy (n = 41) were analyzed. Costs were repeatedly measured during 36 months by interview and patient registries. Primary outcome measures were proportion of recovered patients as measured with the Structured Clinical Interview for DSM-IV Axis II Personality Disorders for the cost-effectiveness analysis, and quality-adjusted life-years (QALYs) for the cost-utility analysis. Bootstrap replications in the cost-effectiveness and the cost-utility planes were used to estimate the probability that one treatment was more cost-effective than the other. Mixed gamma regression on net monetary benefit</p>

						<p>for different levels of willingness to pay for extra effects was used as sensitivity analysis. Additional sensitivity analyses were done to assess robustness of the results.</p> <p>RESULTS</p> <p>Due to higher clinical effects and lower costs, schema therapy was dominant over the other treatments in the cost-effectiveness analyses. Schema therapy has the probability of being the most cost-effective treatment (78% at €0 to 96% at €37,500 [\$27,375] willingness to pay per extra recovery). Treatment as usual was more cost-effective than clarification-oriented psychotherapy due to lower costs. In the cost-utility analysis, schema therapy had a stable 75% probability of being cost-effective. Sensitivity analyses confirmed these findings.</p> <p>CONCLUSIONS</p> <p>The results support the cost-effectiveness of schema therapy but not of clarification-oriented psychotherapy.</p> <p>TRIAL REGISTRATION</p> <p>Netherlands Trial Register NTR566.</p>	
Banaschewski, Tobias; Häge, Alexander; Hohmann, Sarah; Mechler, Konstantin	2023	Perspectives on ADHD in children and adolescents as a social construct amidst rising prevalence of diagnosis and medication use	Frontiers in psychiatry	14		1289157	<p>The diagnosis of attention-deficit hyperactivity disorder (ADHD) is based on the presence of pervasive, persistent symptoms of inattention and/or hyperactivity/impulsivity typically emerging early in life and resulting in significant functional impairment. In contrast to a worldwide epidemiological prevalence of approximately 5% in children and 2-3% in adults, there are significant variations in the prevalence of administrative ADHD diagnoses and medication use. We assert that in order to explore the underlying dynamics of this phenomenon, a thorough understanding of the construct ADHD is necessary. We contend that ADHD is not a natural entity that unfolds within an individual and can be understood independent from societal and environmental factors, but</p>

							rather that ADHD as a diagnosis can better be conceptualized as a valid and pragmatically useful social construct. Decisions to diagnose and treat ADHD should follow a person-centered approach and be focused on functional impairment within a socially constructed, context-dependent and environmentally contingent model.
Banham, James A.; Schweitzer, Robert D.	2017	Therapeutic conversations: Therapists' use of observational language contributes to optimal therapeutic outcomes	Psychology and psychotherapy	90	3	264–278	<p>OBJECTIVE Reflexivity is the process of critically examining one's own experience. Emerging literature suggests that reflexivity is a positive predictor of outcomes in psychotherapy. However, limited research has been conducted regarding therapists' use of reflexivity as a therapeutic technique. In particular, we have a limited understanding of how therapists use language to initiate reflexive conversations. This study investigates the characteristics of therapist language that elicit reflexivity focused on internal and external processes.</p> <p>DESIGN AND METHODS Therapeutic outcomes of 42 trainee-therapists who provided psychotherapy to 173 clients were tracked with the OQ-45.2 with the view of identifying client-trainee-therapist dyads (CTTDs) with the best and poorest outcomes. Six best outcome and six poorest outcome CTTDs were identified. Thirty-six therapy transcripts were initially coded with the Narrative Process Coding System to identify each Narrative Process Mode (NPM). Sixty external, internal, and reflexive NPMs (N = 180 NPMs) were randomly selected across all therapy transcripts for the best outcome group and the same number for the poorest outcome group. The Narrative Initiating Language Element Coding Manual, developed for this study, was used to code therapists' use of language to initiate each</p>

							<p>NPM.</p> <p>RESULTS</p> <p>Therapists belonging to the best outcome group utilized more observational language to initiate internal and reflexive NPMs. Therapists belonging to the poorest outcome group evidenced high proportions of questioning language to elicit each NPM.</p> <p>CONCLUSIONS</p> <p>Examining how therapists use language to elicit NPMs provides further insight as to how therapeutic language may contribute to successful therapeutic outcomes.</p> <p>PRACTITIONER POINTS</p> <p>Reflexive therapeutic conversations characterized by a greater use of observational language were associated with positive therapeutic outcomes. Therapeutic conversations characterized by a high proportion of questioning language were associated with poorer therapeutic outcomes. Supervisors of trainee-therapists have a key role in coaching supervisees to use language that contributes to client treatment outcomes.</p>
Bar, Mor; Saad, Amit; Slonim-Atzil, Dana; Tuval-Mashiach, Rivka; Gour, Tamir; Baron, Noga; Mendlovic, Shlomo	2021	Patient-therapist congruent exchanges engaged with the potential-to-experience is associated with better outcome of psychotherapy	Psychology and psychotherapy	94 Supp 12		304–320	<p>BACKGROUND</p> <p>The concept of potential-to-experience is a major component in psychodynamic theory and assumed to be an important component of psychotherapeutic technique. However, as this assumption has never been empirically tested, the relationship between such interventions and treatment outcome is unclear. The aim of this pilot study is to explore the relationship between patient-therapist congruence of potential-to-experience engaged statements and the outcome of psychodynamic treatments.</p> <p>METHODS</p> <p>Transcripts of 90 sessions from good- and poor-outcome</p>

						<p>treatments (N = 18) were encoded using the MATRIX - a novel content analysis tool of psychodynamic psychotherapy. Based on fixed algorithms, this observer-coding system is designed to identify different types of clinical interventions, including those which focus on the potential-to-experience. Total number of MATRIX codes analysed was 11,125. We compared the total congruence/incongruence ratio of such statements in good and poor treatments. The importance of the congruence/incongruence ratio of the potential-to-experience statements was measured by applying general linear models to classify treatment outcome.</p> <p>RESULTS</p> <p>The congruence/incongruence ratio of the potential-to-experience engaged statements was significantly higher in good treatments. In the best model for classifying treatment outcome based on the congruence/incongruence ratios of several parameters, the congruence/incongruence ratio of the potential-to-experience engaged statements was the single most important predictor.</p> <p>DISCUSSION</p> <p>Maintaining the congruence of potential-to-experience engaged statements within the therapeutic session is associated with better clinical outcome. This provides an initial empirical indication to the importance of the potential-to-experience discourse in psychotherapy praxis.</p> <p>PRACTITIONER POINTS</p> <p>The concept of potential-to-experience is a major component in psychodynamic theory and assumed to be an important component of psychotherapeutic technique. The current results suggest that the ability of</p>
--	--	--	--	--	--	--

							both patient and therapist to maintain the congruence of potential-to-experience statements within the session may improve clinical outcomes. These findings suggest a practical approach for a better management of the therapeutic process. Mainly, it recommends therapists to implement a very careful, active listening to potential-to-experience-related content throughout the session, while highlighting the patient's associations for their potential to become new modus operandi. Moreover, the current study presents an integrative, micro-level tool that enables the translation of complex theoretical concepts in psychotherapy into measurable constructs, aiming at the creation of a bridge between clinical theory and evidence-based practice.
Barbosa, Eunice; Couto, Ana Bela; Basto, Isabel; Stiles, William B.; Pinto-Gouveia, Jos; Salgado, Joo	2018	Immersion and distancing during assimilation of problematic experiences in a good-outcome case of emotion-focused therapy	Psychotherapy research: journal of the Society for Psychotherapy Research	28	2	313–327	Some studies have suggested that a decrease in immersion (egocentric perspective on personal experiences) and an increase in distancing (observer perspective on personal experiences) are associated with the resolution of clinical problems and positive outcome in psychotherapy for depression. To help clarify how this change in perspectives relates to clinical change, the present study compared changes in immersion and distancing across therapy with progress in one client's assimilation of her problematic experiences. We analyzed all passages referring to the central problematic experience in a good-outcome case of emotion-focused therapy for depression using the Measure of Immersion and Distancing Speech and the Assimilation of Problematic Experiences Scale. Results showed that immersion and distancing were associated with different stages of assimilation. Immersion was associated with stages of emerging awareness and clarification of the problem and in the application of new understandings to

							daily life. Distancing was associated with problem-solving and attaining insight. The decrease of immersion and increase of distancing associated with therapeutic improvement should not be taken as a recommendation to avoid immersion and encourage distancing. Immersion and distancing may work as coordinated aspects of the processes of psychotherapeutic change.
Barbosa, Eunice; Silva, Sara; Pinto-Gouveia, José; Salgado, João	2019	How and when immersion and distancing are useful in emotion focused therapy for depression	Psychotherapy research : journal of the Society for Psychotherapy Research	29	6	737-751	Objective: The potential benefit or harm of immersion (egocentric perspective) and distancing (observer perspective) on negative experiences are unclear and have not been empirically investigated in therapy. This is a first exploratory study aimed to analyze and compare the perspectives adopted on reflection (immersion and distancing) of negative experiences across therapy and the relationship between them and depressive symptoms in contrasting therapeutic outcomes of emotion-focused therapy (EFT). Method: Three good-outcomes cases and three poor-outcomes cases of EFT, diagnosed with mild to moderate depression at the beginning of therapy, were randomly selected. Immersion and distancing on negative experiences were analyzed using the measure of immersed and distanced speech. The depressive symptoms were assessed by the Beck Depression Inventory-II. Results: Significant differences across sessions were only found in the good-outcome cases which showed a significant decrease of immersion and an increase of distancing, and this evolution pattern was found related to the reduction of symptoms. Moreover, at the beginning of therapy, distancing was higher in the poor-outcome cases rather than in the good-outcome cases. Conclusion: The progressive and significant evolution from higher immersion at the initial phase to

							higher distancing in the final phase may be helpful in EFT for depression.
Barg, Michael; Galliker, Mark; Speierer, Gert-Walter; S, Holger; Mller, Arnulf	2017	Schwerpunktthema: Wenn Seele und Krper leiden: Der Personzentrierte Ansatz in der Psychosomatik. (Mit 5 Einzelbeitrgen)	Gesprchspsychotherapie und Personzentrierte Beratung	48	2	70–88	Basierend auf Vortrgen und Workshops des Castrup-Rauxeler Gesprchspsychotherapie-Symposiums der rztlichen Gesellschaft fr Psychotherapie wird der personzentrierte Ansatz in der Psychosomatik beleuchtet. Grundlagen des Verhltnisses zwischen Leib und Seele und der personzentrierten Therapie bei somatoformen Strungen werden betrachtet sowie ein kongruenzbasiertes Behandlungskonzept erlutert und ein Blick auf psychologische Ursachen von Herz-Kreislauf-Symptomen geworfen. Bar-Kalifa, Eran; Prinz, Jessica N.; Atzil-Slonim, Dana; Rubel, Julian A.; Lutz, Wolfgang; Rafaeli, Eshkol	2019	Physiological synchrony and therapeutic alliance in an imagery-based treatment	Journal of Counseling Psychology	66	4	508–517	Client–therapist synchrony in various channels (e.g., self-reported affect or physical movement) has been shown as a key process in the construction and development of therapeutic alliance. However, psychophysiological synchrony between clients and therapists has been understudied, with the few extant studies typically relying on single-session data, and no studies examining it within the context of emotion-focused techniques. The main aim of the current paper is to examine the role of client–therapist physiological synchrony during segments of one emotion-focused technique—namely, imagery (IM) work—in predicting therapeutic alliance, and to compare it to the role of synchrony during segments of more traditional cognitive–behavioral (CB) techniques. We conducted an open-trial study in which 31 clients with test anxiety received a 6-session protocol-based treatment. Both clients’ and therapists’ electrodermal activity (EDA) were continuously assessed during sessions. The physiological measures for 5 sessions each (N = 128) were used to compute client–therapist synchrony in IM and CB segments. Therapeutic alliance was assessed using the Session Alliance Inventory. Client–therapist dyads’ synchrony during IM and CB segments was, on average, greater than chance. Synchrony varied mostly at the session (vs. the dyad) level. Multilevel analyses revealed that the synchrony within IM segments (but not within CB segments) was

							significantly associated with the therapeutic bond aspect (but not the task/goal aspects) of alliance. Physiological synchrony during emotion-focused IM is tied to the bond component of the therapeutic alliance at the session level. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Barker, Paige C.; Holland, Neal P.; Shore, Oliver; Cook, Robert L.; Zhang, Yang; Warring, Carrie D.; Hagen, Melanie G.	2021	The Effect of Health Literacy on a Brief Intervention to Improve Advance Directive Completion: A Randomized Controlled Study	Journal of primary care & community health	12		2150132 7211000 221	OBJECTIVE: Completion of an advance directive (AD) document is one component of advanced care planning. We evaluated a brief intervention to enhance AD completion and assess whether the intervention effect varied according to health literacy. METHODS: A randomized controlled study was conducted in 2 internal medicine clinics. Participants were over 50, without documented AD, no diagnosis of dementia, and spoke English. Participants were screened for health literacy utilizing REALM-SF. Participants were randomized in a 1:1 ratio to the intervention, a 15-minute scripted introduction (grade 7 reading level) to our institution's AD forms (grade 11 reading level) or to the control, in which subjects were handed blank AD forms without explanation. Both groups received reminder calls at 1, 3, and 5 months. The primary outcome was AD completion at 6 months. RESULTS: Five hundred twenty-nine subjects were enrolled; half were of limited and half were of adequate health literacy. The AD completion rate was 21.7% and was similar in the intervention vs. the control group (22.4% vs 22.2%, P = .94). More participants with adequate health literacy completed an AD than those with limited health literacy (28.4% vs 16.2%, P = .0008), although the effect of the intervention was no different within adequate or limited literacy groups. CONCLUSION: A brief intervention had no impact on AD completion for subjects of adequate or limited health literacy. PRACTICE

							IMPLICATIONS: Our intervention was designed for easy implementation and to be accessible to patients of adequate or limited health literacy. This intervention was not more likely than the control (handing patients an AD form) to improve AD completion for patients of either limited or adequate health literacy. Future efforts and research to improve AD completion rates should focus on interventions that include: multiple inperson contacts with patients, contact with a trusted physician, documents at 5th grade reading level, and graphic/video decision aids. TRIAL REGISTRATION NUMBER: NCT02702284, Protocol ID IRB201500776.
Barkham, Michael	2016	Patient-centered assessment in psychotherapy: Toward a greater bandwidth of evidence	Clin Psychol Sci Pract (Clinical Psychology: Science and Practice)	23	3	284–287	
Barkham, Michael; Saxon, David; Hardy, Gillian E.; Bradburn, Mike; Galloway, Deanna; Wickramasekera, Nyantara; Keetharuth, Anju D.; Bower, Peter; King, Michael; Elliott, Robert; Gabriel,	2021	Person-centred experiential therapy versus cognitive behavioural therapy delivered in the English Improving Access to Psychological Therapies service for the treatment of	The lancet. Psychiatry	8	6	487–499	BACKGROUND: The UK Government's implementation in 2008 of the Improving Access to Psychological Therapies (IAPT) initiative in England has hugely increased the availability of cognitive behavioural therapy (CBT) for the treatment of depression and anxiety in primary care. Counselling for depression-a form of person-centred experiential therapy (PCET)-has since been included as an IAPT-approved therapy, but there is no evidence of its efficacy from randomised controlled trials (RCTs), as required for recommendations by the National Institute for Health and Care Excellence. Therefore, we aimed to examine whether PCET is cost effective and non-inferior to CBT in the treatment of moderate and severe depression within the IAPT service. METHODS: This

<p>Lynne; Kellett, Stephen; Shaw, Susan; Wilkinson, Toni; Connell, Janice; Harrison, Phillippa; Ardern, Kerry; Bishop-Edwards, Lindsey; Ashley, Kate; Ohlsen, Sally; Pilling, Stephen; Waller, Glenn; Brazier, John E.</p>		<p>moderate or severe depression (PRaCTICED): a pragmatic, randomised, non-inferiority trial</p>				<p>pragmatic, randomised, non-inferiority trial was done in the Sheffield IAPT service in England and recruited participants aged 18 years or older with moderate or severe depression on the Clinical Interview Schedule-Revised. We excluded participants presenting with an organic condition, a previous diagnosis of personality disorder, bipolar disorder, or schizophrenia, drug or alcohol dependency, an elevated clinical risk of suicide, or a long-term physical condition. Eligible participants were randomly assigned (1:1), independently of the research team, and stratified by site with permuted block sizes of two, four, or six, to receive either PCET or CBT by use of a remote, web-based system that revealed therapy after patient details were entered. Those assessing outcomes were masked to treatment allocation. Participants were seen by appropriately trained PCET counsellors and CBT therapists in accordance with the IAPT service delivery model. Depression severity and symptomatology measured by the Patient Health Questionnaire-9 (PHQ-9) at 6 months post-randomisation was the primary outcome, with the PHQ-9 score at 12 months post-randomisation being a key secondary outcome. These outcomes were analysed in the modified intention-to-treat population, which comprised all randomly assigned patients with complete data, and the per-protocol population, which comprised all participants who did not switch from their randomised treatment and received between four and 20 sessions. Safety was analysed in all randomly assigned patients. The non-inferiority margin was set a priori at 2 PHQ-9 points. Patient safety was monitored throughout the course of therapy, adhering to service risk procedures for monitoring serious adverse events. This trial is registered</p>
--	--	--	--	--	--	--

						<p>at the ISRCTN Registry, ISRCTN06461651, and is complete. FINDINGS: From Nov 11, 2014, to Aug 3, 2018, 9898 patients were referred to step three treatments in the Sheffield IAPT service for common mental health problems, of whom 761 (7.7%) were referred to the trial. Of these, we recruited and randomly assigned 510 participants to receive either PCET (n=254) or CBT (n=256). In the PCET group, 138 (54%) participants were female and 116 (46%) were male, and 225 (89%) were White, 16 (6%) were non-White, and 13 (5%) had missing ethnicity data. In the CBT group, 155 (61%) participants were female and 101 (39%) were male, and 226 (88%) were White, 17 (7%) were non-White, and 13 (5%) had missing ethnicity data. The 6-month modified intention-to-treat analysis comprised 401 (79%) of the enrolled participants (201 in the PCET group; 200 in the CBT group) and the 12-month modified intention-to-treat analysis comprised 319 participants (167 in the PCET group; 152 in the CBT group). The 6-month per-protocol analysis comprised 298 participants (154 in the PCET group; 144 in the CBT group). At 6 months post-randomisation, PCET was non-inferior to CBT in the intention-to-treat population (mean PHQ-9 score 12.74 [SD 6.54] in the PCET group and 13.25 [6.35] in the CBT group; adjusted mean difference -0.35 [95% CI -1.53 to 0.84]) and in the per-protocol population (12.73 [SD 6.57] in the PCET group and 12.71 [6.33] in the CBT group; 0.27 [95% CI -1.08 to 1.62]). At 12 months post-randomisation, there was a significant adjusted between-group difference in mean PHQ-9 score in favour of CBT (1.73 [95% CI 0.26-3.19]), with a 95% CI exceeding the 2-point non-inferiority margin. There were two deaths, one death by suicide in the PCET group and one due to chronic obstructive</p>
--	--	--	--	--	--	--

							<p>pulmonary disease in the CBT group. Both were assessed by the responsible clinician to be unrelated to the trial. In terms of using emergency departments for depression-related events, four people (three in the PCET group; one in the CBT group) made more than a single use and six people (three in the PCET group; three in the CBT group) made a single use. One patient in the PCET group had inpatient treatment for a depression-related event.</p> <p>INTERPRETATION: This trial is the first to examine the two most frequently administered psychological therapies in the IAPT service. The finding of non-inferiority of PCET to CBT at 6 months supports the results from large, routine, non-randomised datasets from the IAPT programme. Given the high demand for psychological therapies and the need for patient choice, our findings suggest the need for continued investment in the training and delivery of PCET for improving short-term outcomes, but suggest that PCET might be inferior to CBT at 12 months.</p> <p>FUNDING: British Association for Counselling and Psychotherapy Research Foundation.</p>
Barreto, João F.; Matos, Paula Mena	2018	Mentalizing countertransference? A model for research on the elaboration of countertransference experience in psychotherapy	Clinical psychology & psychotherapy	25	3	427–439	<p>As a construct, the elaboration of countertransference experience (ECE) is intended to depict the implicit and explicit psychological work to which therapists submit their experiences with clients. Through ECE, defined as a mentalizing process of a particular kind, therapists' experiences are presumed to acquire and increase in mental quality and become available for meaning-making and judicious clinical use. In this paper, we claim that such an ongoing process facilitates engagement with common therapeutic factors, such as the therapeutic alliance and countertransference management, enhancing therapist responsiveness in psychotherapy. We synthesize relevant literature on countertransference,</p>

							<p>mentalization, and, in particular, therapists' mentalization, informed by a systematic literature review. As a result, we propose a model for assessing ECE in psychotherapy, comprising 6 diversely mentalized countertransference positions (factual-concrete, abstract-rational, projective-impulsive, argumentative, contemplative-mindful, and mentalizing), 2 underlying primary dimensions (experiencing, reflective elaboration), and 5 complementary dimensions of elaboration. Strengths and limitations of the model are discussed.</p>

Bar-Sella, Avigail; Nof, Aviv; Baucom, Brian R.; Goldstein, Pavel; Romanov, Sergei; Shpakouskaya, Iryna; Kaplun, Dmitrii; Zilcha-Mano, Sigal		The prognostic role of emotion regulation dynamics in the treatment of major depressive disorder	Journal of consulting and clinical psychology	91	12		<p>Objective: The potential prognostic role of emotion regulation in the treatment of major depressive disorder (MDD) has been highlighted by transtheoretical literature and supported by promising empirical findings. The majority of the literature is based on self-report observations at a single snapshot, thus little is known about the prognostic value of moment-to-moment dynamic evolvement of emotion. The present study is the first to examine the prognostic value of both intra- and interpersonal, moment-to-moment emotion regulation dynamics, and the potential moderating effect of the type of treatment. Method: To assess the prognostic value of emotion regulation dynamics, we focused on the first session, using 6,780 talk-turns within 52 patient-therapist dyads. Emotion regulation dynamics were measured using fundamental frequencies of the voice and were calculated using empirical Bayes residuals of the actor-partner interdependence model. Symptomatic change was measured using the Hamilton Rating Scale for Depression across 16 weeks of supportive treatment (ST)</p>

							or supportive–expressive treatment (SET). Results: Findings suggest that patients who show less regulated intrapersonal dynamics during the first session show less reduction of symptoms throughout treatment ($\beta = .26$, $p = .019$). Findings further suggest that this association is mitigated when these patients receive SET, as opposed to ST ($\beta = .72$, $p = .020$). Conclusions: The findings demonstrate the ability of first-session emotion regulation dynamics to serve as a prognostic variable. The findings further suggest that the adverse effect of emotion regulation dynamics on the patient’s prognosis can be mitigated by explicit work on changing maladaptive emotional patterns. Bar-Sella, Avigail; Randall, Ashley K.; Zilcha-Mano, Sigal	2022	Understanding interdependence of patients’ and therapists’ affect experiencing: Examination at sample and individual difference levels	Journal of Counseling Psychology	69	2	188–198	The importance of interdependence processes of patients’ and therapists’ affect experiences (AEs) over the course of treatment has been highlighted by numerous therapeutic orientations. Yet, most studies have focused on snapshot observations and there is a dearth of knowledge regarding session-to-session patient-therapist AE interdependence, through which the dynamics of AE across treatment can be explored. Using actor-partner interdependence model analysis in a sample of 70 patient–therapist dyads across 16 sessions of psychodynamic treatment, the present study investigated whether (a) at the sample level, patients’ and therapists’ changes in positive and negative AEs are interdependent throughout treatment, and (b) whether individuals’ differences in AE interdependence can be explained by patients’ anticipated or general ability to form a strong therapeutic alliance, and by the actual alliance with the therapist during treatment. Findings suggest that patients’ and therapists’ changes in positive and negative AEs are

							interdependent throughout treatment. Moderation analysis suggests that when patients report stronger anticipated ability to form a strong alliance, an increase in therapists' negative AE from one session to another predicts a greater decrease in their patients' negative AE in the following session. Additionally, focusing on patients' actual alliance with the therapist during treatment, when patients report a stronger alliance with their therapist, a subsequent increase in therapists' positive and negative AEs from one session to another predicts greater subsequent increases in their patients' positive and negative AEs in the next session. Taken together, findings suggest that patients' and therapists' AEs are interdependent throughout treatment, though individual differences exist. Barthelmeh, Daniel	2023	Dem Prozess vertrauen. Der Bielefelder Klientenerfahrungsbogen und sein Nutzen für die personzentrierte Arbeit	Gesprächspsychotherapie und Personzentrierte Beratung	54	2	14-19	Der Bielefelder Klientenerfahrungsbogen (BIKEB) ist ein bewährtes Instrument, das Psychometrie mit personzentrierter Haltung verbindet. In der Intervention oder als Metaebene, zusammen mit Klientinnen und Klienten betrachtet, bietet er ein wertvolles Instrument prozessualer Diagnostik und Intervention. Er ist diagnostisch gesehen eine statistische Urteilsbildung, die unter anderem die Klient-Berater/Coach-Beziehung valide abbildet. Das Spannungsfeld, diagnostisch und personzentriert zugleich zu sein, ist ausgehend von Rogers häufig und viel diskutiert worden, beispielsweise ausführlich in den Lehrbüchern von Gerhard Stumm und Wolfgang Keil (Keil & Stumm, 2014) oder Jochen Eckert, Eva-Maria Biermann-Ratjen und Diether Hger (Eckert et al., 2012). Diagnostik bzw. statistische Urteilsbildung lässt sich, richtig angewandt, mit personzentrierter Haltung vereinen und letztlich sogar darin verorten. Dieser Beitrag

							mchte die Frage "Was und wie sollten wir messen?" im personzentrierten Rahmen beantworten, fr den BI- KEB als wirkmchtiges Hilfsmittel werben und uns nicht zuletzt Mut und Selbstvertrauen in einem schwierigen Coachingmarkt zusprechen.
Barthel-Rsing, Marita; Haubl, Rolf	2017	Was ist gruppenanalytische Supervision?	Gruppenpsychotherapie und Gruppendynamik	53	2	118-137	<p>Informiert wird ber die gruppenanalytische Supervision. Sie beruht auf Konzeptualisierungen von unterschiedlichen Referenztheorien und einem Verstdnis, das alle psycho- und soziodynamischen Modellvorstellungen umfasst, die ihren Fokus auf Intersubjektivitt und dabei im Besonderen auf Gruppen und andere situationsberdauernde Mehr- und Vielpersonen-Vergemeinschaftungen legen. In den Problemfeldern einer Organisation sind immer Abwehrprozesse dynamisch wirksam, die durchgearbeitet werden mssen, um die unbewussten Inhalte mit den Affekten, die an anderen Inhalten Zndstoff liefern, in Zusammenhang zu bringen und sie so bewusst und emotional zugnglich werden zu lassen. Dabei entspricht die Integration von fallbezogenen, teambezogenen und institutionellen Aspekten der gruppenanalytischen Haltung mit ihrer oszillierenden Wahrnehmung, wobei alle Aspekte grundstzlich gleichzeitig gegenwrtig sind. Die Gruppe ist in gruppenanalytischem Verstehen Resonanzboden und Agens der Wirksamkeit. Supervisor/in und Supervisionsgruppe sind Container fr das Unverarbeitete. Im professionellen Alltag sich unter dem Druck institutioneller Zwnges immer wieder Denkrume zu verschaffen und diese Zwnges durch die Kommunikation mit anderen bewusst und in ihren Zusammenhngen transparent werden zu lassen, kann zur Haltung und zur Gruppen- und Organisationskultur werden.</p>

<p>Bartholomew, Theodore T.; Gundel, Brittany E.; Sullivan, John W.; Pérez-Rojas, Andrés E.; Lockard, Allison J.</p>	<p>2019</p>	<p>Pretreatment counseling experiences, stressors, and support differences between transgender and cisgender university students seeking mental healthcare</p>	<p>Journal of clinical psychology</p>	<p>75</p>	<p>6</p>	<p>933–957</p>	<p>OBJECTIVES Our aim was to explore rates of prior counseling experiences as well as pretreatment stressors and supports among transgender university students seeking psychotherapy services in university counseling centers.</p> <p>METHODS We used regression models to explore relationships between gender identity and prior mental health experiences, risk-related experiences, traumatic experiences, and support among clients (cisgender: n = 162,305; transgender: n = 545) seeking treatment at 136 university counseling centers.</p> <p>RESULTS Results demonstrate more previous mental health service utilization and greater frequency of some prior stressors transgender clients. Findings indicate the odds of transgender clients reporting drug and alcohol concerns are lower than the reference group. Additionally, transgender clients report less familial support but more social support than cisgender clients.</p> <p>CONCLUSION We discuss the importance of these findings through a more holistic lens that recognizes both stressors as well as positive factors that may more accurately characterize the experiences of transgender clients.</p>
<p>Bartholomew, Theodore T.; Kang, Ellice; Joy, Eileen E.; Robbins, Krista A.; Maldonado-Aguiñiga, Sergio</p>	<p>2022</p>	<p>Clients' perceptions of the working alliance as a predictor of increases in positive affect</p>	<p>Journal of Psychotherapy Integration</p>	<p>32</p>	<p>3</p>	<p>310–325</p>	<p>The working alliance is routinely touted, and empirically supported, as a common factor and robust predictor of decreases in psychological distress. However, advances in more balanced, positively-oriented perspectives in psychotherapy have led to calls to conceptualize therapeutic success as both the decrease of distress and the increase of positive factors. One such positive characteristic that may be enhanced during</p>

							<p>psychotherapy is positive affect. Engendering positive affect has been considered a common process to psychotherapy but remains underexplored in relation to therapeutic processes common across. If the alliance is a robust predictor of decreases in distress, it may also predict increases in positive affect. To explore this hypothesis, we collected data for this naturalistic psychotherapy study from a doctoral training clinic. Participants (N = 102; 1,118 sessions) completed measures of positive affect, distress, and the alliance at every session. Using multilevel modeling, we disaggregated distress and alliance coefficients into within-participant and between-participants effects. Accounting for session number as a linear growth covariate, we found that increases in participants' perceptions of their alliance with their therapists significantly predicted increases in positive affect over the course of treatment. We confirmed the multilevel result using cross-lagged panel modeling via SEM, which indicated that increases in the alliance predict increases in positive affect. The alliance, though a meaningful predictor of distress reduction, is a common factor useful in predicting more than distress reduction alone. Implications for a more balanced conceptualization of outcome and applying positive psychology to psychotherapy are discussed. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Bartholomew, Theodore T.; Keum, Brian T.; Lockard, Allison J.; Pérez-Rojas, Andres E.;	2023	Measurement invariance and psychometric properties of the CCAPS-62 and -34 for	Journal of clinical psychology	79	5	1261–1279	<p>OBJECTIVES International students attending universities in the United States may encounter psychological distress related to their adjustment and experiences studying in a new context and seek services from university counseling centers. Many centers use the Counseling Center</p>

Robbins, Krista A.; Zhao, Fanghui		international student clients					<p>Assessment of Psychological Symptoms (CCAPS) to measure psychological distress in college counseling centers. However, this scale has not been tested for measurement invariance with international students. Our purpose was to explore the measurement invariance of the CCAPS-62 and -34 for international students.</p> <p>METHODS</p> <p>We tested measurement invariance for both versions of the scale using data from over 107,000 university students in psychotherapy at university counseling centers. We also examined construct validity and internal consistency.</p> <p>RESULTS</p> <p>Invariance testing indicated the measurement models of the CCAPS-62 and -34 are equivalent between both groups.</p> <p>CONCLUSION</p> <p>These findings are discussed in light of utilizing this widely-used scale in United States university/college counseling centers with international student clients.</p>
Bartholomew, Theodore T.; Pérez-Rojas, Andres E.; Lockard, Allison J.; Joy, Eileen E.; Robbins, Krista A.; Kang, Ellice; Maldonado-Aguiñiga, Sergio	2021	Therapists' cultural comfort and clients' distress: An initial exploration	Psychotherapy	58	2	275–281	<p>The extent to which therapists are comfortable discussing clients' cultural identities in psychotherapy has been considered a valuable component of how therapists integrate clients' cultures into treatment. Cultural comfort specifically reflects a therapist's way of being at ease, relaxed, and open when discussing clients' cultural identities in treatment. Some initial research has demonstrated the relationships between cultural comfort and clinical outcomes, yet this work has relied largely on cross-sectional designs. The purpose of this preliminary study was to use longitudinal psychotherapy data to explore the relationships between clients' perceptions of their therapists' cultural comfort and clients' distress over</p>

						the course of psychotherapy. Data were collected from 48 clients who attended 476 sessions in a doctoral training clinic. Multilevel modeling was used to account for the nested nature of the data. Results showed that, when session number was held constant, within-client increases in their perceptions of their therapists' cultural comfort were predictive of decreases in psychological distress. We discuss these findings in light of the multicultural orientation literature and with respect to the implications for therapists striving to be comfortable with culture in sessions. Bartnicka-Michalska, Aneta; Oleś, Piotr K.	2022	Do interpreting artists follow the way of self-actualization?	The Humanistic Psychologist	50	4	The purpose of this article was to explore how self-concept functions in connection to motivation and well-being in artists. Specifically, we looked for such people who follow the path of self-actualization. In this article, we introduce unique nomothetic data supporting—as we argue—the existence of Rogerian self-concept in a group of interpretive artists (dancers, musicians, and singers). In a larger study focused on motivation and well-being in artists (n = 132), using k-means cluster analysis, we found a small subgroup of artists (11%) characterized by high well-being, motivation, and strength of volition accompanied by low self-concept clarity, whereas in a much larger group, and according to published results, self-concept clarity corresponds with well-being and adaptive functioning. As we argue, there are two ways of optimal psychological functioning in artists: one based on clear self-concept and another on conceptually unclear but phenomenologically obvious self-concept—Rogerian—and both connected with high well-being, motivation, and strength of volition. According to Rogers' phenomenological theory, self-concept is by definition

							flexible, which implies that low self-concept clarity is a result of the process of experience. Interpretive artists from a given group could identify themselves with their self-actualizing artistic activity and experience their selves in terms of an ongoing process; thus, they did not formulate a stable and coherent self-concept. Our reasoning is based on questionnaire data. Thus, further research should combine qualitative and quantitative data on artists' psychological functioning. (PsychInfo Database Record (c) 2022 APA, all rights reserved)
Baruah, Upasana; Varghese, Mathew; Loganathan, Santosh; Mehta, Kala M.; Gallagher-Thompson, Dolores; Zandi, Diana; Dua, Tarun; Pot, Anne Margriet	2021	Feasibility and preliminary effectiveness of an online training and support program for caregivers of people with dementia in India: A randomized controlled trial	International journal of geriatric psychiatry	36	4	606–617	Objectives: Internet-based interventions involving elements of cognitive behavior therapy, psychoeducation, relaxation and skills training for caregivers of people with dementia have been found to be promising in Western countries. Given these outcomes, the adapted version of a multi-component online caregiver skills training and support program of the World Health Organization, called iSupport, was tested for feasibility and preliminary effectiveness in India. Methods: One hundred fifty-one caregivers of family members with a diagnosis of Alzheimer's disease or dementia were randomized to either the intervention arm (iSupport; n = 74) or to the control group (an education-only e-book program; n = 77). Participants were assessed using self-rated measures of depression and perceived burden, which were the primary outcome measures, at baseline and 3-month follow-up. Person-centered attitude, self-efficacy, mastery and self-rated health were also assessed. Results: Fifty-five caregivers (29 in the iSupport group and 26 in the control condition) completed the study. The recruitment and retention rate of the study were 44.67% and 36.42% respectively. No significant differences were found between the two groups at 3-month follow-up on

						<p>the primary outcomes. Among the secondary outcomes, significant improvement was only seen in caregivers' person-centered attitude towards persons with dementia in the iSupport group ($t = 2.228$; $p < 0.05$). Conclusions: Despite efforts to recruit and retain participants to the online program, this study had a low recruitment and retention rate, which require closer attention and indicates a need for further adaptations of the Indian version of the iSupport program to improve its acceptability and accessibility. The lessons learned from this study will guide the further development of caregiver training and support interventions in India. The trial was registered with the Clinical Trials Registry-India (Trial Registration No. CTRI/2017/02/007876).</p>
Baruch, Rachel Levine; Annunziato, Rachel A.		Outcomes of combined treatment: Evaluating split versus integrated treatment for depression	Professional Psychology: Research and Practice	48	5	<p>As combined medication and psychotherapy is increasingly recommended and provided for patients with depression, clinicians frequently choose between integrated or split treatment delivery with little empirical evidence upon which to base these decisions. The purpose of the current study was to compare outcomes (satisfaction and adherence) between split and integrated treatment for patients with depression. Utilizing a cross-sectional design, 120 adults with major depressive disorder currently receiving combined treatment (60 integrated and 60 split) were recruited on Amazon.com's Mechanical Turk and at Fordham University. Participants were asked to complete measures of satisfaction, adherence, as well as predictors of these variables including preference strength, attachment, symptom severity, and alliance. Importantly, this study did not find overall significant differences in satisfaction or adherence between participants in split and integrated treatment. The results indicated that therapeutic alliance and</p>

							<p>preference strength predicted satisfaction regardless of treatment model, while secure attachment style predicted medication adherence. This study affirms the current practice trends toward split treatment as working equally well for most patients, and supports. Furthermore, findings highlight the person-centered movement's emphasis on therapeutic alliance, and nondiagnostic patient characteristics, in contributing to overall outcome. Therefore, clinicians are encouraged to consider matching patients based on projected alliance and current preference when making such treatment referrals for split or integrated treatment. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>
Basch, Molly C.; Faria, Felipe; Janicke, David M.	2021	Assessing the impact of weight status on pediatric decision-making and medical student awareness of its influence	Stigma and Health		23 76- 69 64(Ele ctr oni c), 23 76- 69 72(Pri nt)	397-407	<p>The objective was to investigate the influence of pediatric patient and mother weight status on assessment/treatment decisions of medical students, as well as student reaction to feedback about differential weight-based decision-making. Medical students (n = 120) viewed vignette scenes of a static virtual human pediatric patient presenting to a physician with back pain, accompanied by her mother. Cues of patient and mother weight (healthy, obesity) were manipulated across scenes. Participants provided ratings on likelihood to recommend pain assessment/treatment and perceptions about the dyad. Real-time individual-level analyses determined the influence of weight cues on decisions. Participants were informed about cue influence. Results show that 60% of participants were influenced by weight cues to make decisions, particularly when considering ordering imaging and physical therapy/psychology referrals. Patient obesity was equated with a higher likelihood to refer. Twenty-five percent of participants were influenced by weight cues when forming</p>

							perceptions; patient and mother obesity was equated with lower anticipated treatment adherence and higher need for follow-up care. Participant awareness of weight cue influence was high and interest in participating in an obesity-related training was moderate. Results suggest that the weight status of pediatric patients and their mothers play a considerable role in medical students' pain-related decision-making. Such patterns in decision-making can be appropriate and contribute to necessary differences in care. They can also be inappropriate, such as inferring adherence based on weight status, and have harmful effects. This underscores need for evidence-based research at the intersection of pediatric obesity and pain and medical education in obesity. (PsycInfo Database Record (c) 2021 APA, all rights reserved)
Basto, Isabel Morais; Stiles, William B.; Rijo, Daniel; Salgado, João	2018	Does assimilation of problematic experiences predict a decrease in symptom intensity?	Clinical psychology & psychotherapy	25	1	76–84	<p>UNLABELLED</p> <p>The assimilation model describes therapeutic change as an integration of experiences that had previously been problematic, distressing, avoided, or warded off. This study assessed whether assimilation was associated with treatment outcome in a sample of psychotherapeutic treatments for depression. Further, it assessed the direction of the association-whether increasing assimilation predicted decreases in symptom intensity or decreasing symptom intensity predicted increases in assimilation.</p> <p>METHOD</p> <p>Participants were 22 clients with mild to moderate depression drawn from a clinical trial comparing cognitive behavioral therapy with emotion-focused therapy. The direction of prediction between assimilation progress and changes in self-reported symptom intensity was assessed.</p>

							<p>RESULTS</p> <p>The assimilation progress was shown to be a better predictor of decreases in symptom intensity than the reverse.</p> <p>CONCLUSION</p> <p>The results supported the assimilation model's suggestion that assimilation progress promotes decreases in symptom intensity in the treatment of clients with major depressive disorder.</p>
Batista, João; Silva, Joana; Magalhães, Carina; Ferreira, Helena; Fernández-Navarro, Pablo; Gonçalves, Miguel M.	2020	Studying psychotherapy change in narrative terms: The innovative moments method	Couns and Psychother Res (Counselling and Psychotherapy Research)	20	3	442-448	
Battle, Jordi de; Benítez, Ivan D.; Moncusí-Moix, Anna; Androustos, Odysseas; Angles Barbastro, Rosana; Antonini, Alessio; Arana, Eunat; Cabrera-Umpierrez, Maria Fernanda;	2023	GATEKEEPER's Strategy for the Multinational Large-Scale Piloting of an eHealth Platform: Tutorial on How to Identify Relevant Settings and Use Cases	Journal of medical Internet research	25		e42187	<p>BACKGROUND: The World Health Organization's strategy toward healthy aging fosters person-centered integrated care sustained by eHealth systems. However, there is a need for standardized frameworks or platforms accommodating and interconnecting multiple of these systems while ensuring secure, relevant, fair, trust-based data sharing and use. The H2020 project GATEKEEPER aims to implement and test an open-source, European, standard-based, interoperable, and secure framework serving broad populations of aging citizens with heterogeneous health needs. OBJECTIVE: We aim to describe the rationale for the selection of an optimal group of settings for the multinational large-scale piloting of the GATEKEEPER platform. METHODS: The selection of implementation sites and reference use cases (RUCs)</p>

<p>Cea, Gloria; Dafoulas, George E.; Folkvord, Frans; Fullaondo, Ane; Giuliani, Francesco; Huang, Hsiao- Ling; Innominato, Pasquale F.; Kardas, Przemyslaw; Lou, Vivian W. Q.; Manios, Yannis; Matsangidou, Maria; Mercalli, Franco; Mokhtari, Mounir; Pagliara, Silvio; Schellong, Julia; Stieler, Lisa; Votis, Konstantinos; Currás, Paula; Arredondo, Maria Teresa; Posada, Jorge; Guillén, Sergio; Pecchia, Leandro; Barbé,</p>																<p>was based on the adoption of a double stratification pyramid reflecting the overall health of target populations and the intensity of proposed interventions; the identification of a principles guiding implementation site selection; and the elaboration of guidelines for RUC selection, ensuring clinical relevance and scientific excellence while covering the whole spectrum of citizen complexities and intervention intensities. RESULTS: Seven European countries were selected, covering Europe's geographical and socioeconomic heterogeneity: Cyprus, Germany, Greece, Italy, Poland, Spain, and the United Kingdom. These were complemented by the following 3 Asian pilots: Hong Kong, Singapore, and Taiwan. Implementation sites consisted of local ecosystems, including health care organizations and partners from industry, civil society, academia, and government, prioritizing the highly rated European Innovation Partnership on Active and Healthy Aging reference sites. RUCs covered the whole spectrum of chronic diseases, citizen complexities, and intervention intensities while privileging clinical relevance and scientific rigor. These included lifestyle-related early detection and interventions, using artificial intelligence-based digital coaches to promote healthy lifestyle and delay the onset or worsening of chronic diseases in healthy citizens; chronic obstructive pulmonary disease and heart failure decompensations management, proposing integrated care management based on advanced wearable monitoring and machine learning (ML) to predict decompensations; management of glycemic status in diabetes mellitus, based on beat to beat monitoring and short-term ML-based prediction of glycemic dynamics; treatment decision support systems</p>

Ferran; Torres, Gerard; Fico, Giuseppe							for Parkinson disease, continuously monitoring motor and nonmotor complications to trigger enhanced treatment strategies; primary and secondary stroke prevention, using a coaching app and educational simulations with virtual and augmented reality; management of multimorbid older patients or patients with cancer, exploring novel chronic care models based on digital coaching, and advanced monitoring and ML; high blood pressure management, with ML-based predictions based on different intensities of monitoring through self-managed apps; and COVID-19 management, with integrated management tools limiting physical contact among actors. CONCLUSIONS: This paper provides a methodology for selecting adequate settings for the large-scale piloting of eHealth frameworks and exemplifies with the decisions taken in GATEKEEPER the current views of the WHO and European Commission while moving forward toward a European Data Space.
Baucom, Donald H.; Kirby, Jennifer S.; Fischer, Melanie S.; Baucom, Brian R.; Hamer, Robert; Bulik, Cynthia M.	2017	Findings from a couple-based open trial for adult anorexia nervosa	Journal of Family Psychology	31	5	584–591	Adult anorexia nervosa (AN) often is persistent, significantly erodes quality of life for both the patient and loved ones, and carries high medical and psychiatric comorbidity. Whereas individual psychotherapy for adult AN leads to improvement in some patients, recent findings indicate that the magnitude of improvement is limited: Only a small percentage of individuals fully recover and dropout rates are high. Thus, it is important to build upon current interventions to improve treatment response. We present results from an open trial of a couple-based intervention for adult anorexia nervosa as an adjunct treatment to standard multidisciplinary care. Twenty couples received treatment over approximately 26 weeks, including a couple-based intervention, individual CBT sessions, psychiatry visits for medication

							management, and nutritional counseling sessions. The results indicate that patients improved at posttest and 3-month follow-up on a variety of AN-related measures, anxiety and depression, and relationship adjustment. Partners also improved on anxiety, depression, and relationship adjustment. In an exploratory analysis, the multicomponent couple treatment intervention was benchmarked to well-conducted randomized controlled trials of individual therapy for AN; the couple intervention seems to compare favorably on AN-related measures and was associated with a lower dropout rate. In spite of methodological limitations, the findings suggest that including partners in the treatment of adult AN holds potential for bolstering treatment outcomes. Bauer, Amy M.; Jakupcak, Matthew; Hawrilenko, Matt; Bechtel, Jared; Arao, Rob; Fortney, John C.	2021	Outcomes of a health informatics technology-supported behavioral activation training for care managers in a collaborative care program	Families, Systems, & Health	39	1	89–100	Introduction: Health informatics-supported strategies for training and ongoing support may aid the delivery of evidence-based psychotherapies. The objective of this study was to describe the development, implementation, and practice outcomes of a scalable health informatics-supported training program for behavioral activation for patients who screened positive for posttraumatic stress disorder and/or bipolar disorder. Method: We trained 34 care managers in 12 rural health centers. They used a registry checklist to document the delivery of 10 behavioral activation skills for 4,632 sessions with 455 patients. Care managers received performance feedback based on registry data. Using encounter-level data reported by care managers, we described the implementation outcomes of patient reach and care manager skill adoption. We used cross-classified multilevel modeling to explore variation in skill delivery accounting for patient characteristics, provider

							<p>characteristics, and change over time. Results: Care managers engaged 88% of patients in behavioral activation and completed a minimum course for 57%. The average patient received 5.9 skills during treatment, with substantial variation driven more by providers (63%) than patients (29%). Care managers significantly increased the range of skills offered to patients over time. Discussion: The registry-based checklist was a feasible training and support tool for community-based providers to deliver behavioral activation. Providers received data-driven performance feedback and demonstrated skill improvement over time, promoting sustainment. Future research will examine patient-level outcomes. Results underscore the potential public health impact of a simple registry-based skills checklist coupled with a scalable remote training program for evidence-based psychotherapy. Baulig, Volkmar	2016	Gestalttherapeutische Arbeit mit Jugendlichen	Gestalttherapie	30	2	58–73	<p>Ein Überblick zur gestalttherapeutischen Arbeit mit Jugendlichen wird gegeben. Die Phase der Jugend ist durch Umbruch, Unsicherheit und Labilität gekennzeichnet. Gestalttherapie stellt durch die inkludierte Wachstumsvorstellung, die Hier-und-Jetzt-Orientierung und durch die Klientenzentrierung eine Chance dar, Jugendliche dosiert anzusprechen. Doch in der gestalttherapeutischen Diskussion spielt die Gestalttherapie mit Jugendlichen nur eine passagere Rolle. Daher werden erfahrungsorientierte Jugendphasen dargestellt und es wird versucht, phasenorientiert Themen und Zugangsformen für die gestalttherapeutische Arbeit zuzuordnen. Ferner werden konkrete Beispiele gestalttherapeutischer Arbeit mit Jugendlichen dargestellt.</p>

Baumann, Margarete	2022	Sexualisierte Gewalt: Die Mehrfachbelastung von Betroffenen und die Gefahr der Retraumatisierung. Bericht aus der Praxis einer personzentrierten Gesprächs- und Focusing-Therapie	Gesprächspsychotherapie und Personzentrierte Beratung	53	2	5-13	Auf der Basis von 35 Jahren personzentrierter Arbeit mit Betroffenen sexualisierter Gewalt stellt die Autorin die besondere Situation ihrer Klientinnen und Klienten dar. Der Fokus liegt auf der Mehrfachbelastung sowie den Gefahren der Retraumatisierung in Familie, Gesellschaft und Gesundheitssystem. Im Artikel wird des Weiteren die Frage gestellt, welche Unterstützung für Betroffene wirklich hilfreich sein kann. Die Autorin beschreibt allgemeine Merkmale der von ihr begleiteten therapeutischen Langzeitprozesse und benennt speziell für diese Personengruppe förderliche therapeutische Haltungen und Interventionen.
Baumgartner, Christian; Bilevicius, Elena; Khazaal, Yasser; Achab, Sophia; Schaaf, Susanne; Wenger, Andreas; Haug, Severin; Keough, Matthew; Hodgins, David; Schaub, Michael P.	2019	Efficacy of a web-based self-help tool to reduce problem gambling in Switzerland: study protocol of a two-armed randomised controlled trial	BMJ open	9	12	e032110	INTRODUCTION: The past-year prevalence of problem gambling worldwide averages 2.3%. Switzerland exhibits a slightly lower past-year prevalence rate, of 1.1%, among adults. Only a minority of these adults attend outpatient treatment. Surveyed problem gamblers have explained that they wanted to handle the problem on their own. The option of a web-based self-help programme could potentially reach those users who hesitate to approach treatment centres and help them to reduce or stop their problem gambling. The effectiveness of such web-based interventions has been shown in other countries. METHODS AND ANALYSIS: This two-armed randomised controlled trial (RCT) will examine the efficacy of a web-based self-help intervention, relative to an active control condition with a self-help manual, at reducing problem gambling. The active intervention programme, spanning 8 weeks, consists of nine modules developed to reduce gambling and attenuate psychopathological comorbidity, including depression, anxiety and stress-related disorder symptoms, relying on motivational interviewing and

							<p>cognitive behavioural therapy. With a target sample size of 352, questionnaire data will be collected at baseline, and at 8 and 24 weeks after baseline. Primary outcomes will be the number of days one has gambled in the last 30 days. Secondary outcomes will include money and time spent on gambling activities, changes in gambling-related problems (Problem Gambling Severity Index, Gambling Symptom Assessment Scale), use of alcohol and cigarettes, and psychopathological comorbidity. All data analysis will comply with the intention-to-treat principle. ETHICS AND DISSEMINATION: The RCT will be conducted in accordance with the Declaration of Helsinki; the consort eHealth Guidelines for studies on medical devices; the European Directive on medical devices 93/42/EEC, Swiss Law and Swiss Regulatory Authority requirements. The study was approved by the ethics committee of the Canton of Zurich. Results will be published in a scientific peer-reviewed journal. Participants will be informed via e-mail about study results via a lay-person-friendly summary of trial findings. TRIAL REGISTRATION NUMBER: Current Controlled Trials registry (ISRCTN16339434).</p>
Baykan, Hayriye; Can, Merve Şahin	2023	Dysfunctional Metacognitive Beliefs, Experiential Avoidance, and Behavioral Inhibition System in Depressive Disorder	Alpha psychiatry	24	4	167–173	<p>BACKGROUND: Dysfunctional metacognitive beliefs form the basis of the formation and maintenance of psychopathologies. In our study, we planned to examine the common aspects of the concepts of dysfunctional metacognition, experiential avoidance, and behavioral inhibition system in depressed patients compared to healthy individuals and their effects on each other. METHODS: Fifty-five depressed patients and as a control group 54 healthy volunteers participated in the study. Beck Depression Inventory, Beck Anxiety Inventory, Metacognitions Questionnaire 30, Acceptance and Action</p>

						<p>Questionnaire II, and Behavioral Inhibition and Behavioral Activation Scale were used in the study. RESULTS: Median (minimum-maximum) Acceptance and Action Questionnaire II score was 9 (7-35) points in the control group and 30 (9-46) points in the depressed patient group ($P < .001$). A statistically significant difference between the groups was observed only in the Behavioral Activation Scale-reward responsiveness subscale, with 20 (14-30) points in the control group and 23 (13-36) points in the patient group. A statistically significant difference was observed between the groups in all Metacognitions Questionnaire 30 subscale scores ($P < .001$). A statistically significant positive correlation was found between depression scores and experiential avoidance ($r = 0.751$; $P < .001$), reward responsiveness ($r = 0.329$; $P < .001$) and metacognition subscale scores. In addition, a positive correlation was found between experiential avoidance and metacognition subscale scores ($P < .001$). CONCLUSION: The data we obtained support the fact that as the severity of depression increases, the patients more strongly stick to dysfunctional metacognitive beliefs, exert more frequently experiential avoidance and less often impulsive behaviors. Considering these clinical features may contribute favorably to the individualized psychotherapy process.</p>
Bcker, Julia	2018	Emotionsfokussierte Therapie				<p>Im Rahmen der Reihe "Therapeutische Skills kompakt" wird eine fundierte und praxisnahe Einföhrung in die Emotionsfokussierte Therapie (EFT) gegeben. Fr die EFT sind Emotionen zentraler Bezugspunkt fr therapeutische Ziele und Interventionen. Eingebettet in die therapeutische Beziehung werden Klienten untersttzt, sich ihrem schmerzhaften emotionalen Erleben bewusst und akzeptierend zuzuwenden, dieses zum Ausdruck zu</p>

							<p>bringen und zu reflektieren. So bekommen sie Zugang zu wichtigen Bedürfnissen, Handlungsimpulsen und adaptiven Emotionen, die ein Motor für erforderliche Veränderungen sind. Die für das praktische Vorgehen relevanten Grundlagen und Konzepte werden vermittelt. Beato-Fernandez, Luis; Muñoz-Martinez, Victoria; Mata-Saenz, Beatriz; Gimeno-Clemente, Natalia; Rojo-Moreno, Luis;	2020	Attitudes towards change mediate the effect of dissociation on psychological outcome in the treatment of eating disorders	European eating disorders review : the journal of the Eating Disorders Association	28	6	724–738	<p>Abstract Objectives The study aimed to examine whether dissociation and attitudes towards change were associated with the psychopathology in patients with eating disorders (EDs) at 1-year follow-up. Method The study included 110 females with anorexia nervosa and bulimia nervosa (48 and 62 respectively). At the beginning of the study and 1 year later, they were assessed by means of the following questionnaires: Dissociative Experiences Scale, Attitudes Towards Change (ACTA), State-Trait Anxiety Inventory, Rosenberg Self-Esteem</p>

Vaz-Leal, Francisco J.; Rodriguez-Cano, Teresa							Scale, Beck Depression Inventory, Eating Attitude Test, Bulimic Investigatory Test Edinburgh and Body Shape Questionnaire (BSQ). Results No statistically significant differences were found between both diagnostic groups regarding dissociation scores. The ACTA at baseline, specifically for patients in the contemplation stage, mediate the effect of dissociation on the psychopathological outcome. Discussion These findings suggest that dissociation might be a transdiagnostic feature related to the EDs outcome. The psychotherapeutic framework must take it into account, particularly in patients in the contemplation stage.
Beblo, Thomas; Pelster, Sarah; Schilling, Christine; Kleinke, Kristian; Iffland, Benjamin; Driessen, Martin; Fernando, Silvia	2018	Breath versus emotions: The impact of different foci of attention during mindfulness meditation on the experience of negative and positive emotions	Behavior therapy	49	5	702-714	Investigated the immediate and delayed effects of breathing meditation, emotion-focused meditation, and a passive viewing control condition on the processing of negative emotions. 65 adult novice meditators (aged 18-62 years) viewed positively or negatively valenced video clips while focusing on breathing, emotion, or in a passive viewing control condition. Results indicate that breathing meditation and emotion-focused meditation may constitute effective emotion regulation strategies to improve the emotional response to negatively valenced stimuli. The effects of both mindfulness meditations appeared to be similar with few advantages for the breathing meditation. Thus, both meditations may contribute to beneficial effects of mindfulness-based therapy programs such as MBSR. Future studies to investigate the effects of mindfulness on more intense emotional states to verify whether clinicians should make breathing meditation and/or emotion-focused meditation available to patients in emotional challenging situations were suggested.

<p>Becker, Laura; Mallien, Anne S.; Pfeiffer, Natascha; Brandwein, Christiane; Talbot, Steven R.; Bleich, André; Palme, Rupert; Potschka, Heidrun; Gass, Peter</p>	<p>2023</p>	<p>Evidence-based severity assessment of the forced swim test in the rat</p>	<p>PloS one</p>	<p>18</p>	<p>10</p>	<p>e029281 6</p>	<p>The forced swim test (FST) is a traditional assay, which has been used for more than 40 years to assess antidepressant effects of novel drug candidates. In recent years, a debate about the test has focused on the assumption that the FST is highly aversive and burdening for the animals because of the earlier anthropomorphic interpretation and designation as a "behavioral despair test". The Directive 2010/63/EU and the German Animal Welfare law require a prospective severity classification of the planned experimental procedures. Still, an objective examination of the animals' burden in this test has not been performed yet. To fill this gap, we conducted an evidence-based severity assessment of the forced swim test in rats according to a 'standard protocol' with a water temperature of 25°C. We examined parameters representing the physiological and the affective state, and natural as well as locomotion-associated behaviors in three separate experiments to reflect as many dimensions as possible of the animal's condition in the test. Hypothermia was the only effect observed in all animals exposed to the FST when using this standard protocol. Additional adverse effects on body weight, food consumption, and fecal corticosterone metabolite concentrations occurred in response to administration of the antidepressant imipramine, which is frequently used as positive control when testing for antidepressant effects of new substances. We conclude that this version of the FST itself is less severe for the animals than assumed, and we suggest a severity classification of 'moderate' because of the acute and short-lasting effects of hypothermia. To refine the FST according to the 3Rs, we encourage confirming the predictive validity in warmer</p>

						water temperatures to allow the rats to maintain physiological body temperature.
Becker, Sara J.; Helseth, Sarah A.; Frank, Hannah E.; Escobar, Katherine I.; Weeks, Brittany J.	2018	Parent preferences and experiences with psychological treatment: Results from a direct-to-consumer survey using the marketing mix framework	Professional Psychology: Research and Practice	49	2	Direct-to-consumer (DTC) marketing strategies represent an increasingly popular approach to promote patient awareness of psychological treatments (PTs). The Marketing Mix is a well-established framework used to inform marketing decisions consisting of four “P’s”: Product (or Service), Promotion, Place, and Price. We conducted the first DTC marketing survey using the Marketing Mix framework to explore how parents concerned about their adolescents’ behavioral health receive information about PTs. A sample of 411 parents (51% girls, 82% non-Hispanic White) of 12- to 19-year-old adolescents completed an online survey asking how they would prefer to receive information about PTs, including five questions spanning the Promotion, Price, and Place dimensions of the Marketing Mix. A subsample of 158 parents also reported on how they had received PT information during their adolescent’s most recent therapy experience, allowing us to compare ideal versus actual therapy experiences. We explored the extent to which experiences varied as a function of parent race/ethnicity, income per capita, parent education level, and adolescent treatment history. Bivariate analyses and multivariate logistic regressions were used to examine which of these variables were associated with parents’ responses to specific survey items. Analyses revealed that parent preferences varied as a function of income per capita, education level, and history of treatment. In addition, there were significant gaps between parents’ ideal and most recent therapy experiences. Implications for the marketing of PTs are discussed. Becker, Sara J.; Midoun, Miriam M.; Zeithaml, Valarie A.; Clark, Melissa A.; Spirito, Anthony	2016	Dimensions of treatment quality most valued by adolescent substance users and their caregivers	Professional Psychology: Research and Practice	47	2	120-129	Professional psychologists are increasingly encouraged to document and evaluate the quality of the treatment they provide. However, there is a significant gap in knowledge about the extent to which extant definitions of treatment quality converge with patient perceptions. The primary goal of this study was to examine how adolescent substance users (ASU) and their caregivers perceive treatment quality. The secondary goal was to determine how these perceptions align with expert-derived definitions of ASU treatment quality and dimensions of perceived quality used frequently in other service disciplines. Focus groups and individual interviews were conducted with 24 ASU and 29 caregivers to explore how participants conceptualize a quality treatment experience. Content analysis identified 3 major dimensions of perceived treatment quality, each of which contained 3 subdimensions: therapeutic relationship (i.e., acceptance, caring, connection), provider characteristics (i.e., experience, communication skills, accessibility), and treatment approach (i.e., integrated care, use of structure, and parent involvement). Results revealed modest convergence between patient perceptions and existing definitions of quality, with several meaningful discrepancies. Most notably, the therapeutic relationship was the most important dimension to ASU and their caregivers, while expert-derived definitions emphasized the treatment approach. Implications for practicing psychologists to enhance training and supervision, quality improvement, and health education initiatives are discussed. Becker-Stoll, Fabienne	2018	Bindung, Lsung und Abbruch	Gesprchspsych otherapie und	49	3	127-131	Basierend auf einem Vortrag im Rahmen des GwG- Jahreskongresses 2018 werden Bindungserfahrungen als

			Personzentrierte Beratung			zentrale Faktoren für eine gelingende Entwicklung charakterisiert und Implikationen für die psychotherapeutische Arbeit abgeleitet. Anhand von Bowlbys Bindungstheorie wird dargelegt, welchen entscheidenden Einfluss frühe Bindungserfahrungen und daraus entstandene interne Arbeitsmodelle auf die Beziehungsgestaltung über die gesamte Lebensspanne haben. Daran anknüpfend wird aufgezeigt, wie der erworbene Bindungsstil den Umgang mit Trennung und Verlust von Bindungspersonen prägt. Schließlich wird die Beziehung zwischen Therapeut und Klient aus bindungstheoretischer Sicht beleuchtet. Hierbei wird dargelegt, wie die Aspekte Bindung und Lösung in der therapeutischen Beziehung gestaltet werden können, um Klienten in Phasen von Lösung, Beziehungsabbruch und Verlusten gut begleiten zu können.
Bedford, Shannon; Repa, Lily; Renouf, Alysha	2020	Supervision in interprofessionaler education: Benefits, challenges, and lessons learned	Journal of Psychotherapy Integration	30	1	As interprofessional teamwork and collaboration in health care becomes a larger component of a psychologist's role, there is a growing need for training and supervision in this competency area. The interprofessional education (IPE) at Memorial University of Newfoundland provides psychology doctoral students with didactic and experiential training in collaborative practice supervised by a practitioner from another discipline. The cross-disciplinary supervision provided in IPE is associated with a unique supervisory experience, in which supervision of the interprofessional competency occurs in a group with students from other disciplines, and the supervisor-supervisee relationship is less clearly defined as compared with typical psychologist-trainee supervision. In this paper, three doctoral students involved in the Memorial IPE training will discuss their experiences with supervision in IPE, highlighting benefits

							and challenges of cross-disciplinary supervision, and applications of the IPE training in a clinical setting. While there are a number of differences and challenges associated with the supervision received by the three students in IPE, this training has been found to be useful preparation for working on interprofessional teams and gaining insight and appreciation into the roles of various professionals on health care teams. Befort, Christie A.; VanWormer, Jeffrey J.; Desouza, Cyrus; Ellerbeck, Edward F.; Gajewski, Byron; Kimminau, Kim S.; Greiner, K. Allen; Perri, Michael G.; Brown, Alexandra R.; Pathak, Ram D.; Huang, Terry T-K; Eiland, Leslie; Drincic, Andjela	2021	Effect of Behavioral Therapy With In-Clinic or Telephone Group Visits vs In-Clinic Individual Visits on Weight Loss Among Patients With Obesity in Rural Clinical Practice: A Randomized Clinical Trial	JAMA	325	4	363-372	<p>IMPORTANCE Rural populations have a higher prevalence of obesity and poor access to weight loss programs. Effective models for treating obesity in rural clinical practice are needed.</p> <p>OBJECTIVE To compare the Medicare Intensive Behavioral Therapy for Obesity fee-for-service model with 2 alternatives: in-clinic group visits based on a patient-centered medical home model and telephone-based group visits based on a disease management model.</p> <p>DESIGN, SETTING, AND PARTICIPANTS Cluster randomized trial conducted in 36 primary care practices in the rural Midwestern US. Inclusion criteria included age 20 to 75 years and body mass index of 30 to 45. Participants were enrolled from February 2016 to October 2017. Final follow-up occurred in December 2019.</p> <p>INTERVENTIONS All participants received a lifestyle intervention focused on diet, physical activity, and behavior change strategies. In the fee-for-service intervention (n = 473), practice-employed clinicians provided 15-minute in-clinic individual visits at a frequency similar to that reimbursed by Medicare (weekly for 1 month, biweekly for 5 months,</p>

						<p>and monthly thereafter). In the in-clinic group intervention (n = 468), practice-employed clinicians delivered group visits that were weekly for 3 months, biweekly for 3 months, and monthly thereafter. In the telephone group intervention (n = 466), patients received the same intervention as the in-clinic group intervention, but sessions were delivered remotely via conference calls by centralized staff.</p> <p>MAIN OUTCOMES AND MEASURES</p> <p>The primary outcome was weight change at 24 months. A minimum clinically important difference was defined as 2.75 kg.</p> <p>RESULTS</p> <p>Among 1407 participants (mean age, 54.7 [SD, 11.8] years; baseline body mass index, 36.7 [SD, 4.0]; 1081 [77%] women), 1220 (87%) completed the trial. Mean weight loss at 24 months was -4.4 kg (95% CI, -5.5 to -3.4 kg) in the in-clinic group intervention, -3.9 kg (95% CI, -5.0 to -2.9 kg) in the telephone group intervention, and -2.6 kg (95% CI, -3.6 to -1.5 kg) in the in-clinic individual intervention. Compared with the in-clinic individual intervention, the mean difference in weight change was -1.9 kg (97.5% CI, -3.5 to -0.2 kg; P = .01) for the in-clinic group intervention and -1.4 kg (97.5% CI, -3.0 to 0.3 kg; P = .06) for the telephone group intervention.</p> <p>CONCLUSIONS AND RELEVANCE</p> <p>Among patients with obesity in rural primary care clinics, in-clinic group visits but not telephone-based group visits, compared with in-clinic individual visits, resulted in statistically significantly greater weight loss at 24 months. However, the differences were small in magnitude and of uncertain clinical importance.</p>

Behme- Matthiessen, Ulrike; Pletsch, Thomas; Scholz, Michael; Klappstein, Kerstin; Hofmann, Susann	2016	Praxis Familiengruppe. Materialien zur Multifamilienthe rapie				Materialien zur Multifamilienthherapie werden prsentiert. Die Eltern-Kind-Gruppentherapie ist ein multifamilienthapeutischer Ansatz, der Eltern und Kindern Begegnungsmglichkeiten erffnet, indem sie persnliche und familire Themen gemeinsam gestalterisch bearbeiten. Sie verbindet einen erfahrungsorientierten Ansatz mit der Vermittlung von Strategien, setzt dabei am Selbsthilfedanken an und frdert somit das Zutrauen in die eigenen Mglichkeiten. Die gemeinsame gestalterische Aktion erffnet die Mglichkeit, dass Eltern und Kinder sich positiv begegnen. Untersttzt von anderen Eltern und begleitet von den Therapeuten knnen neue Strategien erarbeitet und ausprobiert werden. Dabei dient die Gruppe als Ideengeber fr gegenseitige Anregungen. Vor diesem Hintergrund wird eine bersicht geboten ber alle Gruppenaktionen, die sich in der Eltern-Kind-Gruppentherapie bewhrt haben und das Handwerkszeug zur Durchfhrung eigener Gruppen bilden. Zur Illustration der Gruppenaktionen sind werden Beispiele angefhrt. - Inhalt: (1) Einleitung. (3) Tren ffnen: Die Arbeit mit Familiengruppen (Einfhrung; Mentalisieren; Resilienz und Salutogenese). (4) Strukturen und Kontexte (Eltern-Kind-Gruppentherapie; Vater-Kind-Gruppe; Arbeit mit Familiengruppen in der Schule). (5) Gruppenaktionen (Themen: Familie und Identitt; Strken und Ressourcen; Vergangenheit und Zukunft; Kooperation; Mentalisieren; Abschluss) (6) Forschungsbeitrge (Kerstin Klappstein: Frauen in der Multifamilienthherapie!; Susanne Hoffmann: Multifamilienthherapie. Eine qualitative Interviewstudie mit teilnehmenden Eltern zur Evaluation der ressourcenfrdernden Intervention). - Das Buch wurde fr

							die vorliegende Ausgabe bearbeitet und erweitert (Die erste Ausgabe erschien unter dem Titel "Rume, Trume, Grenzen - Materialien zur themenorientierten Eltern-Kind-Gruppentherapie").
Behn, Alex J.; Errázuriz, Paula A.; Cottin, Marianne; Fischer, Candice	2018	Change in symptomatic burden and life satisfaction during short- term psychotherapy: Focusing on the role of family income	Couns and Psychother Res (Counselling and Psychotherapy Research)	18	2	133-142	
Behr, Michael	2019	"The facts are always friendly" - Wirksamkeit Personzentriert- Experienzieller Psychotherapie und Beratung	Gesprchspsych otherapie und Personzentrierte Beratung	50	3	28-37	Es wird ein berblick ber Primrstudien sowie Metaanalysen zur Wirksamkeit der personenzentriert-experienziellen Psychotherapie im Vergleich zu anderen Psychotherapieerfahren gegeben. Sowohl vergleichende Primrstudien als auch groe Metaanalysen belegten hierbei, dass die groen Psychotherapieverfahren alle hnlich wirksam waren. Die personenzentriert-experienzielle Psychotherapie schnitt hnlich gut ab wie kognitiv-behaviorale Psychotherapie, vor allem wenn die Studien die Forscherzugehrigkeit statistisch bercksichtigten. Auch in benachbarten Anwendungsfeldern wie der Filialtherapie, dem Motivational Interviewing, dem Gordon-Training und insgesamt im schulisch-erzieherischen Feld belegten Metaanalysen die signifikante Wirksamkeit personenzentrierten Vorgehens. Limitierungen der metaanalytischen Methode, vor allem bei der Auswahl der eingeschlossenen Studien, fhrten in Einzelfllen aber zu fachlich unbegrndeten Artefakten.

Behr, Michael	2020	"The facts are always friendly". Wirksamkeit Personenzentriert- Experienzieller Psychotherapie und Beratung	Person	24	2	107-118	<p>Ein Überblick in Form eines qualitativen Reviews zu den Wirksamkeitsforschungen und vor allem Metaanalysen der personenzentrierten experienziellen Psychotherapie wird gegeben. Sowohl vergleichende Primärstudien als auch große Metaanalysen belegen, dass die großen Psychotherapieverfahren alle ähnlich wirksam sind. Insbesondere die Personenzentriert-Experienzielle Psychotherapie (PZEP) schneidet ähnlich gut ab wie Kognitiv-Behaviorale Psychotherapie (CBT), vor allem wenn die Studien die Forscher-Zugehörigkeit rechnerisch berücksichtigen. Dies zeigen auch viele Studien der Kinder- und Jugendlichenpsychotherapie. Personenzentriert-Experienzielles Arbeiten schneidet im Vergleich zu klassisch klientenzentriertem noch etwas günstiger ab. Qualitative Studien bestätigen die personenzentrierte Theorie über Klient*innenprozesse und relativieren den ausschließlichen Blick auf Symptome. Gleichwohl gibt es inzwischen so viele strungsspezifische personenzentrierte Wirksamkeitsstudien, dass auch Metaanalysen strungsspezifische Wirksamkeitsmaße angeben können. Auch in benachbarten Anwendungsfeldern wie der Filialtherapie, dem Motivational Interviewing, dem Gordon-Training und insgesamt im schulisch-erzieherischen Feld belegen Metaanalysen signifikante Wirksamkeit personenzentrierten Vorgehens. Empirische Psychotherapieforschung ist schon historisch mit Rogers und dem personenzentrierten Konzept untrennbar verbunden. Sein Bonmot "the facts are always friendly" weist ihn als unbestechlichen Forscher aus. Freundlich sehen auch die meisten CBT-Forschenden PZEP. Limitierungen der metaanalytischen Methode, vor allem bei der Auswahl der eingeschlossenen Studien, führen in</p>

Behr, Michael; Beutel, Helmuth	2021	Erinnerungen an Reinhard Tausch	Gesprächspsych otherapie und Personzentrierte Beratung	52	4	22–23	Am 6. November 2021 wurde Reinhard Tausch 100 Jahre alt geworden. Der GwG bleibt er als einer der einflussreichsten Vertreter des Personzentrierten Ansatzes in Erinnerung. Er war Mitbegründer des Verbandes und Wegbereiter der Gesprächspsychotherapie in Deutschland. Er starb am 8. August 2013. Zwei langjährige GwGler erinnern sich zurück.
Behr, Michael; Finke, Jobst; Gahleitner, Silke Birgitta	2016	Entwicklung ist Offenheit - Antworten an Jochen Eckert. Hat die Gesprächspsych otherapie/Person zentrierte Psychotherapie eine Zukunft? Eine Stellungnahme zu dem Beitrag von Behr, M., Finke J., Gahleitner, S. B. (2016). "Personzentriert sein - Sieben Herausforderun gen der Zukunft". PERSON 40 (1):	Person	20	2	101	Eine Antwort auf J. Eckerts kritische Sicht auf die Zukunft der Personzentrierten Psychotherapie (im gleichen Heft) in Deutschland wird vorgelegt. Nach einer Würdigung Eckerts Verdienste wird auf seine einzelnen Kritikpunkte eingegangen, die sich auf Begrifflichkeiten und Terminologie bezüglich Aktualisierungstendenz, Therapietechnik, Kongruenz und Echtheit, sowie das Ausbleiben empirischer Studien, fehlende Zitationen und die deutsche gesundheitspolitische Situation beziehen.

		14-30 - im gleichen Heft					
Behr, Michael; Finke, Jobst; Gahleitner, Silke Birgitta	2016	Personzentriert sein - Sieben Herausforderungen der Zukunft. 20 Jahre PERSON und 30 Jahre nach Rogers' Tod	Person	20	1	14-30	Berichtet wird über Potenziale, den Personzentrierten Ansatz konzeptionell weiterzuentwickeln. Unter stetem Bezug auf Carl Rogers und unter Einbezug aktueller Entwicklungen werden folgende Perspektiven vorgeschlagen: personzentriertes Denken mge (1) Konzepte von Strungen in personzentrierte Konstrukte integrieren und die Aktualisierungstendenz auch strungsspezifisch beschreiben; (2) das Bindungsbedrfnis neben der Selbstaktualisierung als gleichrangiges anthropologisches Bestimmungselement der Person sehen; (3) die Symbolisierung von Erfahrungen eher als ein Konstruieren denn als ein Aufdecken verstehen; (4) die Idee der Nicht-Direktivitt entradikalisieren; (5) die Bedeutung von Interventionstechniken neben den klientenzentrierten Kernbedingungen und Grundhaltungen strker profilieren; (6) die Strungs- und Vernderungstheorie ber das klassische Inkongruenzmodell hinaus weiterentwickeln; (7) bei psychosozialen Problemlagen und in der sozialen Arbeit bzw. Beratung Interventionskonzepte entwickeln, die die Vernetzung der Person strker bercksichtigen.
Behr, Michael; Hson, Dorothea	2020	Interaktion in der Personzentrierten Spieltherapie	Gesprchspsych ootherapie und Personzentrierte Beratung	51	1	11-16	Vorgestellt werden Grundlagen der therapeutischen Interaktion im Rahmen der personzentrierten Spieltherapie mit Kindern. Von zentraler Bedeutung ist hierbei die interaktionelle Resonanz, die ein empathisches und wertschzendes Eingehen auf die Spielthemen des Kindes beschreibt, ohne Gleichgltigkeit oder Dominanz aufzuweisen. Auf diese Weise kann die Spieltherapie positive Interaktions- und Bindungserfahrungen ermöglichen und kognitive Schemata verndern, was letztlich auch zu einem

							positiveren Selbsterleben des Kindes führen kann. Zur Veranschaulichung wird abschließend die Interaktionsresonanz Skala (IRS) vorgestellt, auf der mit Hilfe von Ankerbeispielen die therapeutische Interaktionsresonanz ermittelt werden kann, die sich idealer Weise in der Mitte zwischen den Extrempolen gleichgültig/unbeteiligt und direktiv/dominant befindet.
Behr, Michael; Hsson, Dorothea; Luderer, Hans- Jürgen; Vahrenkamp, Susanne	2017	Gespräche hilfreich führen. Band 1: Praxis der Beratung und Gesprächspsych otherapie: Personzentriert - erlebnisaktiviere nd - dialogisch					Gerichtet an alle Berufsgruppen, die im psychosozialen und medizinischen Hilfesystem arbeiten, wird im ersten Band eines zweibändigen Werks zur hilfreichen Gesprächsführung Grundlagenwissen für die Praxis der Beratung und Gesprächspsychotherapie vermittelt. Dabei wird deutlich gemacht, dass person- und klientenzentriertes Vorgehen heute mehrheitlich als einfühlsam, wertschätzend und echt zu sein: Im Gespräch wird heute eine dialogische Beziehung angeboten, in der Erlebensprozesse aktiviert werden, mit konfligierenden Selbstanteilen gearbeitet wird sowie mit Träumen, Körpererfahrungen und Rollenspielen. Darüber hinaus werden Entscheidungsdilemmata und Lösungsfindungen aktiv unterstützt. Rubriken wie Theorien, Kontroverses, Historie oder Zusammenfassungen sollen das Lesen erleichtern. Zur Illustration werden Beispiele herangezogen. Lese-, Web-Tipps und ein Vernetzungs-Kosmos verorten darüber hinaus das Vorgehen in der Fachwelt. - Inhalt: (1) Die Persönlichkeitstheorie (Entwicklungstheorie; Veränderungstheorie; Interventionstheorie; Theorie seelischer Gesundheit). (2) Die helfende Beziehung: drei Kernbedingungen und zwei Beziehungsangebote (einfühlsam reagieren; bedingungslos wertschätzen; Echtheit - Kongruenz; begleitende Beziehung; dialogische Beziehung). (3) Schlüsselstellen im Ablauf von Gesprächen (Kontaktaufnahme und Bedingungsklärung;

						<p>Beziehungsaufbau; Beziehungsfestigung; Klärung von Gefühlen und Motiven; Planen und Handeln; Bewerten; Beendigung der Beratung oder Therapie; Probleme beim Beziehungsaufbau mit Hilfesuchenden). (4) Mehr als drei Kernbedingungen: Erlebnisaktivierende Methoden (Intuition und Körpergefühl - Focusing; innere Stimmen und Selbstanteile - Integration von Methoden der emotionsfokussierten Therapie; Träume; Zeichnen und Gestalten ordnen; Entscheidungsprozesse unterstützen; Problemlösen aktivieren; Konflikte mit Abwesenden im personenzentrierten Rollenspiel bearbeiten). (5) Das fachliche Umfeld der personenzentrierten Beratung und Gesprächspsychotherapie (im Kontext anderer beraterischer/therapeutischer Verfahren; Unterschiede zwischen Beratung und Psychotherapie; personenzentrierte Netzwerke).</p>
Behr, Michael; Hesson, Dorothea; Luderer, Hans-Jürgen; Vahrenkamp, Susanne	2020	Gespräche hilfreich führen. Band 2: Psychosoziale Problemlagen und psychische Strungen in personenzentrierter Beratung und Gesprächspsychotherapie				<p>Grundkompetenzen für die personenzentrierte Beratung und Psychotherapie werden vermittelt. Für komplexere beraterische Herausforderungen und für die Psychotherapie wird anwendungsbezogenes praktisches Wissen gegeben, das aber auch für andere Fachkräfte über den humanistischen Bereich hinaus interessant ist. Zunächst werden das allgemeine und das personenzentrierte Vorgehen für die wichtigsten psychischen Strungen und psychosozialen Problemlagen behandelt, und zwar so, dass dies auch die Vorbereitung auf die Heilpraktikerprüfung stützt. Hinzu kommen die Kapitel zu psychosozialen Problemlagen. Diese beiden Hauptteile werden ergänzt von einer Diskussion des immanenten Widerspruchs des personenzentriert-ganzheitlichen Menschenbildes und einer strungs- und problemlagenspezifischen Sicht - einschließlich Fragen der Diagnostik - sowie von Kapiteln zu settingspezifischem</p>

							<p>Vorgehen, der Wirksamkeit und zu Rechtsfragen. - Inhalt: (A) Psychosoziale Problemlagen. (1) Trennung und Scheidung. (2) Schwere Krankheit. (3) Palliative Care und Hospiz. (4) Trauer. (5) Mobbing (6) Burnout (7) Armut (8) Vereinsamung. (9) Schwere Vernachlässigung, körperliche und sexuelle Gewalt gegen Kinder. (10) Migration und Flucht. (11) Husliche Gewalt. - (B) Psychische Strungen. (12) Diagnosen stellen und zugleich personzentriert sein. (13) ADHS. (14) Schizophrenien. (15) Unipolare Depression und bipolare Strung. (16) Angststrungen. (17) Zwangsstrungen. (18) Trauma- und belastungsbezogene Strungen. (19) Psychische Strungen mit körperlichen Beschwerden, Krankheitsangst, körperlichen Funktionsstrungen und dissoziativen Symptomen. (20) Essstrungen. (21) Strungen durch Alkohol und andere psychotrope Substanzen. (22) Demenzen und andere psychische Strungen als Folge einer Hirnschdigung. (23) Persnlichkeitsstrungen. - (C) Zielgruppen. (23) Paare. (24) Selbsterfahrungsgruppen und Gruppenpsychotherapie. (25) Eltern und Familien - Erziehungsberatung und Familientherapie. (26) Jugendliche. - (D) Wirksamkeit: Belege fr ein personzentriertes Vorgehen. (27) "The facts are always friendly". Wirksamkeit Personzentriert- Experimentieller Psychotherapie und Beratung.</p>
Beintner, Ina; Jacobi, Corinna	2018	Are we overdosing treatment? Secondary findings from a study following women with bulimia nervosa	The International journal of eating disorders	51	8	899-905	<p>OBJECTIVE Provision of eating disorder (ED) treatment in practice is often guided by national health service structures rather than evidence-based treatment recommendations. Especially for more severely or chronically ill patients, clinicians seem to advocate a "the more the better" strategy of treatment provision. Exploring the dose-response relationship in ED treatment may shed light on both beneficial and detrimental effects of prolonged</p>

		after inpatient treatment				<p>treatment provision.</p> <p>METHOD</p> <p>We utilized data from 64 women from the treatment-as-usual (TAU) group of a randomized controlled trial on Internet-based aftercare for women with bulimia nervosa who had received inpatient treatment. We examined the relationship between treatment duration and dose and (1) baseline patient characteristics and (2) treatment outcomes (abstinence from binge eating and compensatory behaviors, frequency of binge eating and vomiting, thin ideal internalization, and general psychopathology) at 18-month follow up.</p> <p>RESULTS</p> <p>On average, the women in our study were hospitalized for 9 weeks and most received high doses of subsequent outpatient psychotherapy (median: 45 sessions). The severity of symptoms that a patient experienced at hospital admission or discharge was largely unrelated to the amount of outpatient treatment she subsequently received. Longer inpatient treatments or higher doses of subsequent outpatient treatment did not result in more favorable outcomes.</p> <p>DISCUSSION</p> <p>Our findings suggest that, instead of providing costly long treatment without evidenced benefit to patients, there is a need for further exploration of and discussion about the risks and benefits of providing high doses of treatment for both individuals and the health care system.</p>
Beitel, Mark; Myhra, Laurelle L.; Gone, Joseph P.; Barber, Jacques P.;	2018	Psychotherapy with American Indians: An exploration of therapist-rated	Psychotherapy	55	1	<p>The aim of the project was to conduct psychotherapy research in American Indian mental health clinics. To date, very little psychotherapy research has been conducted in this area. We report the findings from a multisite investigation of psychotherapy techniques used</p>

<p>Miller, Alyssa; Rasband, Aaron; Cutter, Christopher J.; Schottenfeld, Richard S.; Barry, Declan T.</p>		<p>techniques in three urban clinics</p>					<p>with American Indians. Psychotherapists, working in three American Indian clinics, were asked to self-report the therapeutic interventions that they used in sessions with 93 separate adult American Indian outpatients. Each therapist rated each client exactly once, and thus data on 93 sessions were collected. Therapists' self-reported technique use with the Multitheoretical List of Therapist Interventions (McCarthy & Barber, 2009). Ratings were made immediately following the delivery of a session. The common factors approach was the most reported approach, followed by person-centered and interpersonal approaches. However, the therapists reported using techniques from all of the main therapeutic approaches. Technique use was affected by client- (demographic and diagnostic), therapist-, and therapy-related variables. This project represents a promising start to systematic psychotherapy research in busy, urban American Indian clinics. Many psychotherapeutic techniques are utilized, and there are many avenues for future research. A replication with client and observer ratings will be an important next step. <p>Békés, Vera; Aafjes-van Doorn, Katie; Roberts, Kailey E.; Stukenberg, Karl; Prout, Tracy; Hoffman, Leon</p>	<p>2023</p>	<p>Adjusting to a new reality: Consensual qualitative research on therapists' experiences with teletherapy</p>	<p>Journal of clinical psychology</p>	<p>79</p>	<p>5</p>	<p>1293–1313</p>	<p>OBJECTIVE In the wake of the COVID-19 pandemic, the use of teletherapy has become more pervasive than ever. Many therapists faced this move to a remote setting with little experience or training. We aimed to qualitatively examine therapists' subjective experience of providing teletherapy, including changes in technique, the therapeutic relationship, and the therapeutic process. METHODS Thirty-one psychotherapists participated in semistructured interviews. Interviews were recorded,</p>

						<p>then transcribed and analyzed using the Consensual Qualitative Research method.</p> <p>RESULTS</p> <p>Therapists typically reported a change in the therapeutic relationship in terms of an increased sense of disconnection as well as shifts in various aspects of the relational dynamics, and they also typically experienced differences in the therapy process due to changes in patient and therapist engagement in the therapeutic work. Additionally, some therapists also reported that they became more active and directive in sessions, took a more informal, personal, or relaxed approach to interacting with patients, and while the emotional connection changed and they missed the energy and intimacy of in-person sessions, the relationship in telesessions felt more authentic and human for some, and teletherapy also provided a way to discuss new dimensions in the process.</p> <p>CONCLUSION</p> <p>Overall, these results suggest great variability in therapists' subjective experiences with teletherapy, and present teletherapy as a distinct therapy format in many aspects. Further process-level research and subsequent training is needed to better equip therapists to navigate teletherapy's challenges and harness its unique opportunities.</p>	
Belizer, Cara M.; Vagedes, Jan	2019	High-resolution infrared body surface temperature and self-perceived warmth	Journal of Psychophysiology		21 51- 21 24(Ele ctr oni	139-147	<p>Anorexia nervosa (AN) is associated with thermoregulatory disturbances such as hypothermia. However, few studies have explored body warmth in AN patients. In this study, we assessed the body surface temperature distribution in adolescent AN patients using high-resolution infrared thermal imaging and through a patient questionnaire, and explored how this differed</p>

		distribution in adolescent anorexia nervosa patients			c), 02 69- 88 03(Pri nt)		between intervention and control group and length of treatment. Adolescent AN patients admitted to a multimodal inpatient treatment programme based on an integrative perspective were assessed at three time-points: admission (t1), 6 weeks post-admission (t2), and 3 months after t2 (t3). Healthy control participants were assessed once at baseline. In both groups we assessed participants' surface temperature and the perception of warmth, using thermal imaging and a questionnaire, in the face, hands, abdomen, and feet. We recruited 40 AN patients and 40 healthy controls, who were admitted to the treatment programme for an average of 70 days (SD = 24.07). The AN patients were significantly colder in all chosen body domains, except the abdomen area, at t1 compared to healthy controls at baseline. The questionnaire findings supported this result. Differences between the intervention and control groups noted at t1 were significantly reduced by t2 and t3. Our findings suggest that abnormalities in the body warmth distribution of AN patients are reversible after having received an AN-specific treatment. Reducing the loss of warmth could improve therapeutic outcomes in AN patients and be a predictor of recovery, and should be investigated in further studies. Bell, Toby; Dixon, Alison; Kolts, Russell	2017	Developing a Compassionate Internal Supervisor: Compassion-Focused Therapy for	Clinical psychology & psychotherapy	24	3	632-648	UNLABELLED The concept of an 'internal supervisor' has been used in psychotherapy to describe the way in which the supervisory relationship is internalized and utilized by the supervisee. This research explores the possibility, and potential benefit, of training therapists to develop a 'compassionate internal supervisor'. A training programme was developed for trainee cognitive-

		Trainee Therapists				<p>behavioural therapists using adapted versions of compassion-focused therapy interventions. The training focused on guided imagery exercises and reflective practices undertaken for a 4-week period. Seven trainee cognitive-behavioural therapists were interviewed, utilizing a semi-structured format, regarding their experience of the training programme. The resulting transcriptions were analysed using Interpretative Phenomenological Analysis (IPA). The analysis identified six super-ordinate themes: (1) the varied nature of the supervisor image, (2) blocks and their overcoming, (3) increased compassion and regulation of emotion, (4) impact on cognitive processes, (5) internalization and integration, and (6) professional and personal benefit. The themes describe the varied ways in which participants created and experienced their compassionate supervisor imagery. Working with the personal blocks encountered in the process provided participants with a deeper understanding of the nature of compassion and its potential to support them in their training, practice and personal lives. The process and impact of 'internalizing' a compassionate supervisory relationship is described by participants and then discussed for potential implications for psychotherapy training and self-practice. Copyright © 2016 John Wiley & Sons, Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Compassion-focused therapy, and related compassionate-mind imagery exercises, can be adapted specifically to develop compassion in trainee psychotherapists. Creating, and engaging with, an 'ideal compassionate supervisor' in an imaginal form can support psychotherapy trainees in their clinical practice and development, their supervision and their personal</p>

							lives. The cultivation of therapist self-compassion can reduce unhelpful cognitive processes such as worry, rumination and self-criticism whilst increasing self-reflection, attentional flexibility and approach behaviour. Identifying, and working with, blocks to compassion is important when cultivating clinician self-compassion. Therapist self-practice of compassion-focused exercises can provide important insights into the nature of compassion and its cultivation in clients.
Belsher, Bradley E.; Beech, Erin; Evatt, Daniel; Smolenski, Derek J.; Shea, M. Tracie; Otto, Jean Lin; Rosen, Craig S.; Schnurr, Paula P.	2019	Present-centered therapy (PCT) for post-traumatic stress disorder (PTSD) in adults	The Cochrane database of systematic reviews	2019	11		<p>BACKGROUND</p> <p>Present-centered therapy (PCT) is a non-trauma, manualized psychotherapy for adults with post-traumatic stress disorder (PTSD). PCT was originally designed as a treatment comparator in trials evaluating the effectiveness of trauma-focused cognitive-behavioral therapy (TF-CBT). Recent trials have indicated that PCT may be an effective treatment option for PTSD and that patients may drop out of PCT at lower rates relative to TF-CBT.</p> <p>OBJECTIVES</p> <p>To assess the effects of PCT for adults with PTSD. Specifically, we sought to determine whether (1) PCT is more effective in alleviating symptoms relative to control conditions, (2) PCT results in similar alleviation of symptoms compared to TF-CBT, based on an a priori minimally important differences on a semi-structured interview of PTSD symptoms, and (3) PCT is associated with lower treatment dropout as compared to TF-CBT.</p> <p>SEARCH METHODS</p> <p>We searched the Cochrane Common Mental Disorders Controlled Trials Register, the Cochrane Library, Ovid MEDLINE, Embase, PsycINFO, PubMed, and PTSDpubs (previously called the Published International Literature</p>

						<p>on Traumatic Stress (PILOTS) database) (all years to 15 February 2019 search). We also searched the World Health Organization (WHO) trials portal (ICTRP) and ClinicalTrials.gov to identify unpublished and ongoing trials. Reference lists of included studies and relevant systematic reviews were checked. Grey literature searches were also conducted to identify dissertations and theses, clinical guidelines, and regulatory agency reports.</p> <p>SELECTION CRITERIA</p> <p>We selected all randomized clinical trials (RCTs) that recruited adults diagnosed with PTSD to evaluate PCT compared to TF-CBT or a control condition. Both individual and group PCT modalities were included. The primary outcomes of interest included reduced PTSD severity as determined by a clinician-administered measure and treatment dropout rates.</p> <p>DATA COLLECTION AND ANALYSIS</p> <p>We complied with the Cochrane recommended standards for data screening and collection. Two review authors independently screened articles for inclusion and extracted relevant data from eligible studies, including the assessment of trial quality. Random-effects meta-analyses, subgroup analyses, and sensitivity analyses were conducted using mean differences (MD) and standardized mean differences (SMD) for continuous data or risk ratios (RR) and risk differences (RD) for dichotomous data. To conclude that PCT resulted in similar reductions in PTSD symptoms relative to TF-CBT, we required a MD of less than 10 points (to include the 95% confidence interval) on the Clinician-Administered PTSD Scale (CAPS). Five members of the review team convened to rate the quality of evidence across the</p>
--	--	--	--	--	--	--

						<p>primary outcomes. Any disagreements were resolved through discussion. Review authors who were investigators on any of the included trials were not involved in the qualitative or quantitative syntheses.</p> <p>MAIN RESULTS</p> <p>We included 12 studies (n = 1837), of which, three compared PCT to a wait-list/minimal attention (WL/MA) group and 11 compared PCT to TF-CBT. PCT was more effective than WL/MA in reducing PTSD symptom severity (SMD -0.84, 95% CI -1.10 to -0.59; participants = 290; studies = 3; $I^2 = 0\%$). We assessed the quality of this evidence as moderate. The results of the non-inferiority analysis comparing PCT to TF-CBT did not support PCT non-inferiority, with the 95% confidence interval surpassing the clinically meaningful cut-off (MD 6.83, 95% CI 1.90 to 11.76; 6 studies, n = 607; $I^2 = 42\%$). We assessed this quality of evidence as low. CAPS differences between PCT and TF-CBT attenuated at 6-month (MD 1.59, 95% CI -0.46 to 3.63; participants = 906; studies = 6; $I^2 = 0\%$) and 12-month (MD 1.22, 95% CI -2.17 to 4.61; participants = 485; studies = 3; $I^2 = 0\%$) follow-up periods. To confirm the direction of the treatment effect using all eligible trials, we also evaluated PTSD SMD differences. These results were consistent with the primary MD outcomes, with meaningful effect size differences between PCT and TF-CBT at post-treatment (SMD 0.32, 95% CI 0.08 to 0.56; participants = 1129; studies = 9), but smaller effect size differences at six months (SMD 0.17, 95% CI 0.05 to 0.29; participants = 1339; studies = 9) and 12 months (SMD 0.17, 95% CI 0.03 to 0.31; participants = 728; studies = 5). PCT had approximately 14% lower treatment dropout rates compared to TF-CBT (RD -0.14, 95% CI -0.18 to -0.10;</p>
--	--	--	--	--	--	--

							<p>participants = 1542; studies = 10). We assessed the quality of this evidence as moderate. There was no evidence of meaningful differences on self-reported PTSD (MD 4.50, 95% CI 3.09 to 5.90; participants = 983; studies = 7) or depression symptoms (MD 1.78, 95% CI -0.23 to 3.78; participants = 705; studies = 5) post-treatment.</p> <p>AUTHORS' CONCLUSIONS</p> <p>Moderate-quality evidence indicates that PCT is more effective in reducing PTSD severity compared to control conditions. Low quality of evidence did not support PCT as a non-inferior treatment compared to TF-CBT on clinician-rated post-treatment PTSD severity. The treatment effect differences between PCT and TF-CBT may attenuate over time. PCT participants drop out of treatment at lower rates relative to TF-CBT participants. Of note, all of the included studies were primarily designed to test the effectiveness of TF-CBT which may bias results away from PCT non-inferiority. The current systematic review provides the most rigorous evaluation to date to determine whether PCT is comparably as effective as TF-CBT. Findings are generally consistent with current clinical practice guidelines that suggest that PCT may be offered as a treatment for PTSD when TF-CBT is not available.</p>
Belvederi Murri, Martino; Ferrigno, Gabriella; Penati, Simona; Muzio, Caterina; Piccinini, Giulia; Innamorati, Marco; Ricci,	2017	Mentalization and depressive symptoms in a clinical sample of adolescents and young adults	Child Adolesc Ment Health (Child and Adolescent Mental Health)	22	2	69–76	<p>BACKGROUND</p> <p>Increasing evidence supports that mentalization deficits may have a role in the genesis of young age depression; however, few studies examined this issue in clinical populations.</p> <p>METHODS</p> <p>Outpatients aged 14-21, suffering from various psychiatric disorders, were assessed using the Mentalization Questionnaire (MZQ), the Beck Depression</p>

<p>Federica; Pompili, Maurizio; Amore, Mario</p>						<p>Inventory (BDI), and the Childhood Trauma Questionnaire (CTQ), using data from age-matched healthy students for comparison. The relationship between CTQ, MZQ, and BDI scores was examined at the cross-sectional level, including mediation analyses, and longitudinally, in a subsample who underwent a psychotherapy intervention.</p> <p>RESULTS</p> <p>Of 83 subjects, 33 (39.8%) had mentalization levels that were 1 standard deviation below those of comparison subjects. In the whole sample, the levels of mentalization were inversely associated with BDI ($r = -.68, p < .001$) and CTQ scores ($r = -.30, p = .006$). Moreover, MZQ scores mediated a large part of the effect of childhood trauma on depression (total effect: 10.6, 95% CI: 5.3, 15.9; direct effect: 6.5, 95% CI: 2.1, 10.8; indirect effect: 4.1, 95% CI: 1.5, 7.4). This effect was almost entirely explained by the Affect Regulation subscale. In patients re-evaluated after four sessions ($n = 37$), the decrease in BDI scores correlated with the increase in MZQ scores ($r = .40, p = .02$).</p> <p>CONCLUSIONS</p> <p>In a juvenile clinical sample, deficits of mentalization abilities were associated with the severity of depression and explained part of the depressogenic effects of childhood trauma.</p>
<p>Belz, Martina; Schramm, Elisabeth; McCullough Jr., James P.</p>	<p>2013</p>	<p>... und nochmal mit Gefhl</p>				<p>Die Integration emotionsfokussierter Aspekte in die Therapie von Depressionen mit dem "Cognitive Behavioral Analysis System of Psychotherapy" (CBASP) wird beschrieben. Nach einer Definition der Depression als refraktre Stimmungsstrung werden Merkmale emotionaler Beeintrchtigungen und ihre Zusammenhng mit frhen Lebenserfahrungen beschrieben und am Fallbeispiel einer 49-jhrigen sdstasiatischen</p>

							depressiven Patientin verdeutlicht. Anschließend wird die Bedeutung von Emotionen in der Behandlung chronisch depressiver Patienten errtert. Neben Grundannahmen ber die Vernderung von Emotionen im CBASP wird die spezifische Rolle des Therapeuten bei der persnlichen Gestaltung der therapeutischen Beziehung basierend auf der bertragungshypothese beschrieben. Zudem werden Strategien zum Erlernen interpersoneller Auswirkungen von Verhalten und zur Modifikation refraktionrer Emotionalitt (Zukunfts-Situationsanalyse, interpersonelle Diskriminationsbung, Flooding oder Exposition und verhaltensbezogene oder imaginierte Alternativen) vorgestellt und am Fallbeispiel illustriert. Basierend auf berlegungen zu Langzeiteffekten der CBASP-Therapie wird die Bearbeitung refrakter Emotionen mit der emotionsfokussierten Therapie (EFT) in einer zweiten Behandlungsphase diskutiert.
Bender, Stephan	2017	Einfhrung in die Schematherapie aus psychodynamischer Sicht. Eine integrative, schulenbergreif ende Konzeption					Aus psychodynamischer Sicht wird ein einfhrender berblick zur Schematherapie gegeben, und es wird dargelegt, wie sie nicht nur in der Arbeit mit Erwachsenen, sondern auch bei Kindern und Jugendlichen gewinnbringend eingesetzt werden kann. Schemata representieren stabile Reaktions- und Verhaltensmuster, die im Lebenslauf erworben wurden und aktuell als Strelemente die Gestaltung der therapeutischen Beziehung erschweren knnen. Die Schematherapie fokussiert deshalb auf die therapeutische Beziehung und ihre Ausgestaltung. Das Buch richtet sich an tiefenpsychologisch fundiert arbeitende Therapeuten, die nach Mglichkeiten suchen, verhaltenstherapeutische Verfahren wissenschaftlich fundiert in ihre Therapien einzubeziehen. - Inhalt: (A) Theorie: Schematherapeutisches Modell. (1) Warum

							<p>Schematherapie? Geschichte der Entstehung der Schematherapie (Besonderheiten der Schematherapie im Vergleich zur kognitiven Verhaltenstherapie; Was kann Schematherapie nicht?). (2) Schematherapie (Was sind Schemata?; Wie entstehen Schemata?). (3) Das Moduskonzept (Kindmodi; maladaptive Bewältigungsmodi; dysfunktionale Elternmodi; der gesunde Erwachsene, das altersangemessene Kind oder der altersangemessene Jugendliche). (4) Fallkonzeption. (5) Situation in der Kinder- und Jugendlichenpsychotherapie. - (B) Wie funktioniert Schematherapie? Therapeutische Verfahren und Techniken. (6) Phase eins: Diagnostik und Psychoedukation/Etablierung des Strungsmodells. (7) Phase zwei: Veränderung (therapeutische Haltung, Beziehung zwischen Therapeut und Patient; allgemeiner Prozess; kognitive Techniken; emotionsfokussierte Techniken; Aufbrechen von Verhaltensmustern). (8) Weiterführende Literatur (Schematherapie mit Kindern und Jugendlichen; Schematherapie mit Erwachsenen). (9) Evidenz, Wirksamkeit, Ausblick.</p>
Benitez, Cinthia; Southward, Matthew W.; Altenburger, Erin M.; Howard, Kristen P.; Cheavens, Jennifer S.	2019	The within-person effects of validation and invalidation on in-session changes in affect	Personality disorders	10	5	406–415	<p>[Correction Notice: An Erratum for this article was reported in Vol 10(5) of Personality Disorders: Theory, Research, and Treatment (see record 2019-50033-001). In the article, some values in Table 1 were incorrectly marked with asterisks as significant. The corrected table appears in the erratum.] Validation is the accurate reflection of someone’s internal experiences. Validation has been theorized to enhance the process of therapy and facilitate effective outcomes (Lynch, Chapman, Rosenthal, Kuo, & Linehan, 2006). Additionally, validation may play an integral role in reducing emotional arousal specifically for individuals with borderline personality disorder (BPD). There is little research on the relation</p>

						<p>between validation and therapy outcomes such as affect change. In the current study, we tested the relations among self-reported validation and invalidation and in-session changes in positive and negative affect with a sample of 52 clients in treatment. Further, we examined BPD features as a moderator of the relations between self-reported validation and invalidation and in-session changes in affect. We disaggregated within-person from between-person effects using client reports of validation and invalidation during Sessions 3 to 7. Greater within-person validation was associated with decreased postsession negative affect, whereas greater within-person invalidation was associated with increased postsession NA. Neither validation nor invalidation was related to changes in positive affect. Further, at elevated levels of BPD features, validation, but not invalidation, was associated with decreases in negative affect. BPD features did not moderate the relation between validation or invalidation and postsession positive affect. These results provide empirical evidence that patient-reported validation and invalidation predict changes in negative affect during sessions. Additionally, these results suggest that patients with elevated BPD features are particularly responsive to validation during therapy sessions, and as such, provide an avenue for navigating the in-session negative emotional arousal that these patients often experience. Benjamin, Isabel; Rodriguez-Seijas, Craig;	2023	Differences in patient satisfaction across sexual orientation and	Psychology of Sexual Orientation and Gender Diversity	10	1	<p>Sexual and gender minority individuals (SGM) experience higher rates and greater severity of psychopathology than cisgender heterosexual persons. SGM individuals also seek mental health treatment with greater frequency than cisgender heterosexual individuals. Studies have</p>

Zimmerman, Mark		gender identity in an acute care setting					investigated types of SGM affirmative mental health treatment, but few studies have examined whether standard mental health treatment is satisfactory for the SGM community. The current study took place in a general partial hospital program and compared satisfaction with an initial psychiatric meeting and with end-of-treatment satisfaction between cisgender heterosexual and SGM patients. We compared initial satisfaction between (a) cisgender heterosexual patients (N = 1253) and SGM patients (N = 334) and (b) cisgender heterosexual patients and cisgender but not heterosexual patients (N = 276), and transgender or gender diverse (TGD) patients (N = 58). We compared end-of-treatment satisfaction between (a) cisgender heterosexual patients (N = 1044) and SGM patients (N = 284) and (b) cisgender heterosexual patients and cisgender but not heterosexual patients (N = 235), TGD patients (N = 49). SGM patients were less satisfied with their initial psychiatric meeting than non-SGM patients. We found no overall differences in satisfaction between the two groups, but breakdown analyses revealed SGM patients were less satisfied with certain group therapies than non-SGM patients. This exploratory study adds to the nascent research investigating SGM patient satisfaction within one standard acute care setting. Future research into the development of assessment measures for SGM patient satisfaction is encouraged, particularly given the dearth of existing tailored satisfaction measures. Bensel, Wolfgang	2018	Suchttherapie im Wandel - ein Plädoyer für den Erhalt eines	Gesprächspsychotherapie und Personenzentrierte Beratung	49	3	155-159	Auf der Grundlage eines historischen Rückblicks auf die Entstehung der Suchttherapie werden aktuelle Entwicklungen im Versorgungssystem kritisch reflektiert. In der Retrospektive wird aufgezeigt, wie sich in

		erfolgreichen Versorgungssystem					Deutschland schrittweise eine differenzierte Suchthilfe herausgebildet hat, wobei die Verflochtenheit der Maßnahmen mit dem jeweils vorherrschenden Zeitgeist verdeutlicht wird. Es wird auf einen Bruch dieses erfolgreichen Prozesses seit der Finanzkrise 2008 hingewiesen. Argumentiert wird, dass gesellschaftspolitische Entwicklungen dazu geführt haben, dass hierzulande trotz des etablierten und evaluierten Systems, das aus einem dichten Netz aus ambulanten, stationären, betrieblichen und komplementären Einrichtungen und Angeboten besteht, inzwischen deutlich zu wenige Betroffene tatsächlich erreicht werden. Gründe hierfür werden analysierend dargestellt und Handlungsempfehlungen als Gegenmaßnahmen zu diesem Trend ausgesprochen.
Bentley, Kate H.; Boettcher, Hannah; Bullis, Jacqueline R.; Carl, Jenna R.; Conklin, Laren R.; Sauer-Zavala, Shannon; Pierre-Louis, Catherine; Farchione, Todd J.; Barlow, David H.	2018	Development of a Single-Session, Transdiagnostic Preventive Intervention for Young Adults at Risk for Emotional Disorders	Behavior modification	42	5	781–805	Cognitive-behavioral prevention programs have demonstrated efficacy in reducing subclinical symptoms of anxiety and depression, and there is some evidence to suggest that they can lower the risk of future disorder onset. However, existing interventions tend to be relatively lengthy and target specific disorders or problem areas, both of which limit their potential for widespread dissemination. To address these limitations, we aimed to develop a single-session, transdiagnostic preventive intervention based on the Unified Protocol for Transdiagnostic Treatment of Emotional Disorders for young adults at risk for developing anxiety and/or depressive disorders within a college setting. Results from this proof-of-concept study indicated that the intervention was viewed as highly satisfactory and acceptable. The intervention also was successful at delivering adaptive emotion management skills in its 2-hr workshop format. Future studies evaluating the efficacy

							of this novel transdiagnostic, emotion-focused prevention program are warranted.
Bentley, Kate H.; Nock, Matthew K.; Sauer-Zavala, Shannon; Gorman, Bernard S.; Barlow, David H.	2017	A functional analysis of two transdiagnostic, emotion-focused interventions on nonsuicidal self-injury	Journal of consulting and clinical psychology	85	6	632–646	Objective: Nonsuicidal self-injury (NSSI) is prevalent and associated with clinically significant consequences. Developing time-efficient and cost-effective interventions for NSSI has proven difficult given that the critical components for NSSI treatment remain largely unknown. The aim of this study was to examine the specific effects of mindful emotion awareness training and cognitive reappraisal, 2 transdiagnostic treatment strategies that purportedly address the functional processes thought to maintain self-injurious behavior, on NSSI urges and acts. Method: Using a counterbalanced, combined series (multiple baseline and data-driven phase change) aggregated single-case experimental design, the unique and combined impact of these 2 4-week interventions was evaluated among 10 diagnostically heterogeneous self-injuring adults. Ecological momentary assessment was used to provide daily ratings of NSSI urges and acts during all study phases. Results: Eight of 10 participants demonstrated clinically meaningful reductions in NSSI; 6 participants responded to 1 intervention alone, whereas 2 participants responded after the addition of the alternative intervention. Group analyses indicated statistically significant overall effects of study phase on NSSI, with fewer NSSI urges and acts occurring after the interventions were introduced. The interventions were also associated with moderate to large reductions in self-reported levels of anxiety and depression, and large improvements in mindful emotion awareness and cognitive reappraisal skills. Conclusions: Findings suggest that brief mindful emotion awareness and cognitive reappraisal interventions can lead to reductions

							in NSSI urges and acts. Transdiagnostic, emotion-focused therapeutic strategies delivered in time-limited formats may serve as practical yet powerful treatment approaches, especially for lower-risk self-injuring individuals. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Beres, Laura K.; Mwamba, Chanda; Bolton-Moore, Carolyn; Kennedy, Caitlin E.; Simbeza, Sandra; Topp, Stephanie M.; Sikombe, Kombatende; Mukamba, Njekwa; Mody, Aaloke; Schwartz, Sheree R.; Geng, Elvin; Holmes, Charles B.; Sikazwe, Izukanji; Denison, Julie A.	2023	Trajectories of re-engagement: factors and mechanisms enabling patient return to HIV care in Zambia	Journal of the International AIDS Society	26	2	e26067	INTRODUCTION: While disengagement from HIV care threatens the health of persons living with HIV (PLWH) and incidence-reduction targets, re-engagement is a critical step towards positive outcomes. Studies that establish a deeper understanding of successful return to clinical care among previously disengaged PLWH and the factors supporting re-engagement are essential to facilitate long-term care continuity. METHODS: We conducted narrative, patient-centred, in-depth interviews between January and June 2019 with 20 PLWH in Lusaka, Zambia, who had disengaged and then re-engaged in HIV care, identified through electronic medical records (EMRs). We applied narrative analysis techniques, and deductive and inductive thematic analysis to identify engagement patterns and enablers of return. RESULTS: We inductively identified five trajectories of care engagement, suggesting patterns in patient characteristics, experienced barriers and return facilitators that may aid intervention targeting including: (1) intermittent engagement;(2) mostly engaged; (3) delayed linkage after testing; (4) needs time to initiate antiretroviral therapy (ART); and (5) re-engagement with ART initiation. Patient-identified periods of disengagement from care did not always align with care gaps indicated in the EMR. Key, interactive re-engagement facilitators experienced by participants, with varied importance across trajectories, included a desire for

							<p>physical wellness and social support manifested through verbal encouragement, facility outreach or personal facility connections and family instrumental support. The mechanisms through which facilitators led to return were: (1) the promising of living out one's life priorities; (2) feeling valued; (3) fostering interpersonal accountability; (4) re-entry navigation support; (5) facilitated care and treatment access; and (6) management of significant barriers, such as depression. CONCLUSIONS: While preliminary, the identified trajectories may guide interventions to support re-engagement, such as offering flexible ART access to patients with intermittent engagement patterns instead of stable patients only. Further, for re-engagement interventions to achieve impact, they must activate mechanisms underlying re-engagement behaviours. For example, facility outreach that reminds a patient to return to care but does not affirm a patient's value or navigate re-entry is unlikely to be effective. The demonstrated importance of positive health facility connections reinforces a growing call for patient-centred care. Additionally, interventions should consider the important role communities play in fostering treatment motivation and overcoming practical barriers.</p>
Berglas, Nancy F.; Williams, Valerie; Mark, Katrina; Roberts, Sarah C. M.	2018	Should prenatal care providers offer pregnancy options counseling?	BMC pregnancy and childbirth	18	1	384	<p>BACKGROUND: Professional guidelines indicate that pregnancy options counseling should be offered to pregnant women, in particular those experiencing an unintended pregnancy. However, research on whether pregnancy options counseling would benefit women as they enter prenatal care is limited. This study examines which women might benefit from options counseling during early prenatal care and whether women are interested in receiving counseling from their prenatal care provider. METHODS: At four prenatal care facilities in</p>

						<p>Louisiana and Maryland, women entering prenatal care completed a self-administered survey and brief structured interview (N = 586). Data were analyzed through descriptive statistics, bivariate analyses, multivariate multinomial logistic regression, and coding of open-ended responses. RESULTS: At entry into prenatal care, most women reported that they planned to continue their pregnancy and raise the child. A subset (3%) scored as having low certainty about their decision on the validated Decision Conflict Scale, indicating need for counseling. In addition, 9% of women stated that they would be interested in discussing their pregnancy options with their prenatal care provider. Regression analyses indicated some sociodemographic differences among women who are in need of or interested in options counseling. Notably, women who reported food insecurity in the prior year were found to be significantly more likely to be in need of options counseling (RRR = 3.20, $p < 0.001$) and interested in options counseling (RRR = 5.48, $p < 0.001$) than those who were food secure. Most women were open to discussing with their provider if their pregnancy was planned (88%) or if they had considered abortion (81%). More than 95% stated they would be honest with their provider if asked about these topics. CONCLUSIONS: Most women are certain of their decision to continue their pregnancy at the initiation of prenatal care. However, there is a subset of women who, despite entering prenatal care, are uncertain of their decision and wish to discuss their options with their health care provider. Screening tools and/or probing questions are needed to support prenatal care providers in identifying these women and ensuring unbiased, non-directive counseling on all pregnancy options.</p>

Berk, Lesley; Hallam, Karen T.; Colom, Francesc; Vieta, Eduard; Hasty, Melissa; Macneil, Craig; Berk, Michael	2010	Enhancing medication adherence in patients with bipolar disorder	Human psychopharmac ology	25	1	1-16	<p>OBJECTIVES Medication adherence contributes to the efficacy-effectiveness gap of treatment in patients with bipolar disorder. This paper aims to examine the challenges involved in improving medication adherence in bipolar disorder, and to extract some suggestions for future directions from the core psychosocial studies that have targeted adherence as a primary or secondary outcome.</p> <p>METHODS A search was conducted for articles that focused on medication adherence in bipolar disorder, with emphasis on publications from 1996 to 2008 using Medline, Web of Science, CINAHL PLUS, and PsychINFO. The following key words were used: adherence, compliance, alliance, adherence assessment, adherence measurement, risk factors, psychosocial interventions, and psycho-education.</p> <p>RESULTS There are a number of challenges to understanding non-adherence including the difficulty in defining and measuring it and the various risk factors that need to be considered when aiming to enhance adherence. Nevertheless, the importance of addressing adherence is evidenced by the connection between adherence problems and poor outcome. Despite these challenges, a number of small psychosocial studies targeting adherence as a primary outcome point to the potential usefulness of psycho-education aimed at improving knowledge, attitudes, and adherence behavior, but more large scale randomized controlled trials are needed in this area. Evidence of improved outcomes from larger randomized controlled trials of psychosocial interventions that target medication adherence as a</p>
--	------	--	---------------------------------	----	---	------	--

						<p>secondary outcome suggests that tackling other factors besides medication adherence may also be an advantage. While some of these larger studies demonstrate an improvement in medication adherence, the translation of these interventions into real life settings may not always be practical. A person centered approach that considers risk factors for non-adherence and barriers to other health behaviors may assist with the development of more targeted briefer interventions. Integral to improving medication adherence is the delivery of psycho-education, and attention needs to be paid to the implementation, and timing of psycho-education. Progress in the understanding of how medicines work may add to the credibility of psycho-education in the future.</p> <p>CONCLUSIONS</p> <p>Enhancement of treatment adherence in bipolar patients is a necessary and promising management component as an adjunct to pharmacotherapy. The current literature on psychosocial interventions that target medication adherence in bipolar disorder points to the possibility of refining the concept of non-adherence and adapting psycho-education to the needs of certain subgroups of people with bipolar disorder. Large scale randomized controlled trials of briefer or more condensed interventions are needed that can inform clinical practice.</p>
Berry, Natalie; Machin, Matthew; Ainsworth, John; Berry, Katherine; Edge, Dawn; Haddock,	2020	Developing a Theory-Informed Smartphone App for Early Psychosis: Learning Points	Frontiers in psychiatry	11	602861	<p>Background: Actissist is a smartphone app designed to deliver an intervention grounded in cognitive behavior therapy for early psychosis. Actissist was developed by a multidisciplinary team of academics, clinicians, experts by experience and software engineers. Actissist has been tested in two trials, the first a proof-of-concept trial where Actissist was safe, acceptable and feasible, the second, a</p>

<p>Gillian; Lewis, Shon; Morris, Rohan; Bucci, Sandra</p>		<p>From a Multidisciplinary Collaboration</p>				<p>powered randomized controlled trial. Objective: This article describes how our multidisciplinary team designed and developed Actissist. This article describes: (i) how Actissist was informed by initial qualitative interviews and focus groups and an expert reference group; (ii) refinements made to the app based on ongoing user feedback; (iii) successes and challenges encountered; and (iv) learning points and recommendations for involving stakeholders in digital health interventions. Methods: Expert reference group meetings informed the development of Actissist and design of subsequent trials, which included individuals with lived experience of psychosis, clinicians, academics, computer scientists and software engineers. Person-centered stakeholder involvement was promoted using focus groups and qualitative interviews prior to the development of the app, which informed version one of Actissist. Interviews were carried out with participants who had used Actissist. Two further versions of Actissist were developed following additional rounds of testing. Results: Multidisciplinary working throughout the Actissist project led to the development, inclusion and improvement of the app design and content. These changes and features included non-directive and compassionate content, co-designed recovery videos, relaxation exercises, psychoeducation material, ability to "favorite" areas of the app that users found helpful, and goal-setting. Challenges to collaborative working included discrepancies between what stakeholders want and what is technically possible to deliver, resource pressures, trying to deliver desired features within the boundaries of fundamental trial design considerations, and power imbalances associated with multidisciplinary</p>
---	--	---	--	--	--	--

						<p>working. Conclusions: The involvement of stakeholders in the design and development and delivery of Actissist has been fundamental to our development approach. Through this collaborative process, we have identified different perspectives and ideas that would have not been generated by the research team alone. Best, Paul; Meireles, Matilde; Schroeder, Franziska; Montgomery, Lorna; Maddock, Alan; Davidson, Gavin; Galway, Karen; Trainor, David; Campbell, Anne; van Daele, Tom	2022	Freely Available Virtual Reality Experiences as Tools to Support Mental Health Therapy: a Systematic Scoping Review and Consensus Based Interdisciplinary Analysis	Journal of technology in behavioral science	7	1	100–114	The primary purpose of this article is to review the potential therapeutic value of freely available VR content as an addition to the practitioners 'toolkit'. Research has shown that virtual reality (VR) may be useful to extend existing guided imagery-based practices found in traditional mental health therapy. However, the use of VR technology within routine mental health practice remains low, despite recent reductions in equipment costs. A systematic scoping review and interdisciplinary analysis of freely available VR experiences was performed across two popular online databases (SteamVR and Oculus.com). A total of 1785 experiences were retrieved and screened for relevance with 46 meeting the inclusion criteria. VR content was then reviewed for potential therapeutic value by an interdisciplinary panel with experience across a number of therapeutic interventions including cognitive behavioural therapy, Rogerian counselling, mindfulness-based therapies. and family

							therapy. Eleven (22%) of the 50 freely available VR experiences were reported to have therapeutic potential as tools to support routine mental health therapy. These included support with the following mental health issues- low mood, social anxiety, stress reduction and fear of heights. Guidance of a qualified mental health practitioner was recommended in all cases to maximise the benefit of the VR experiences retrieved. While the quality is variable, freely available VR experiences may contain valuable content that could support mental health therapy. This includes as a homework activity or as an initial setting for case formulation and behavioural experiments.
Beuchat, Hélène; Grandjean, Loris; Despland, Jean-Nicolas; Pascual-Leone, Antonio; Gholam, Mehdi; Swendsen, Joel; Kramer, Ueli	2022	Ecological momentary assessment of emotional processing: An exploratory analysis comparing daily life and a psychotherapy analogue session	Couns and Psychother Res (Counselling and Psychotherapy Research)	22	2	345-356	
Beutel, Helmuth	2021	Zum 100. Geburtstag - Erinnerungen an Reinhard Tausch (1921-2013)	Psychotherapeutenjournal	20	4	341	Anlässlich des 100. Geburtstag des Psychologen Prof. Dr. Reinhard Tausch werden seine Beiträge zur Verbreitung der von ihm so betitelten Gesprächspsychotherapie im deutschsprachigen Raum gewürdigt. Zudem wird auf seine Pionierarbeiten hingewiesen, die mit seinem Anspruch, dass seine theoretischen Erkenntnisse praktische Hilfestellungen für den Alltag leisten und auch über den akademischen Fachkreis hinaus verständlich vermittelt

							<p>werden sollten, in Verbindung standen: Ende der 1970er-Jahre, als psychotherapiebezogene Formate ein absolutes Novum im deutschen Fernsehen darstellten, machte Tausch in mehreren TV-Sendungen mit aufgezeichneten gruppentherapeutischen Gesprächen dieses Setting einer größeren Öffentlichkeit bekannt. Ein Anliegen von Tausch war es, die postulierte „therapeutische Wirkung“ einer an personenzentrierten Grundhaltungen orientierten psychologischen Beratung und Gesprächsführung in messbaren Effekten nachzuweisen. Die in diesem Sinne von ihm veranlassten Untersuchungen zu den Therapieergebnissen an der von ihm eingerichteten Beratungsstelle waren zu ihrer Zeit (1969&#150;1974), also lange bevor klinische Wirksamkeitsstudien zum Standardrepertoire in der deutschen Psychotherapie gehörten, ein richtungsweisendes Unterfangen. Zusammenfassend wird festgestellt, dass Tausch mit der Ausarbeitung und Verankerung der Grundideen der Gesprächspsychotherapie wichtige Anregungen für die Gestaltung von therapeutischer Beziehung und Gesprächsführung gegeben hat, von denen die Psychotherapie verfahrensbereit profitieren kann.</p>
Beutel, Manfred E.; Greenberg, Leslie; Lane, Richard D.; Subic-Wrana, Claudia	2019	Treating anxiety disorders by emotion-focused psychodynamic psychotherapy (EFPP) - An integrative, transdiagnostic approach	Clinical Psychology and Psychotherapy	26	1	1-13	<p>Anxiety disorders are characterized by high levels of anxiety and avoidance of anxiety-inducing situations and of negative emotions such as anger. Emotion-focused therapy (EFT) and psychodynamic psychotherapy (PP) have underscored the therapeutic significance of processing and transforming repressed or disowned conflicted or painful emotions. Although PP provides sophisticated means of processing intrapsychic and interpersonal conflict, EFT has empirically tested a set of techniques to access, deepen, symbolize, and transform</p>

							emotions consistent with current conceptualizations of emotions and memory. Based on our clinical experience, we propose that an integrative emotion-focused and psychodynamic approach opens new avenues for treating anxiety disorders effectively, and we present a transdiagnostic manual for emotion-focused psychodynamic psychotherapy. The therapeutic approach takes into account both the activation, processing, and modification of emotion and the underlying intrapsychic and interpersonal conflicts. The short-term treatment is based on the three phases of initiating treatment, therapeutic work with anxiety, and termination. Emotional poignancy (or liveliness) is an important marker for emotional processing throughout treatment. Instead of exposure to avoided situations, we endorse enacting the internal process of generating anxiety in the session providing a sense of agency and access to warded-off emotions. Interpretation serves to tie together emotional experience and insight into the patterns and the nature of underlying intrapersonal and interpersonal conflict. Treatment modules are illustrated by brief vignettes from pilot treatments.
Beutler, Larry E.; Edwards, Christopher; Someah, Kathleen	2018	Adapting psychotherapy to patient reactance level: A meta-analytic review	Journal of clinical psychology	74	11	1952– 1963	Resistance and its extreme variation, reactance, are uniformly observed across varieties of psychotherapy. Social psychologists note that reactant individuals prove to be less so when offered a receptive and nondirective environment. We provide definitions of reactance, review its frequent measures, and offer a clinical example. A meta-analysis of 13 controlled studies (1,208 patients) examined the degree to which treatment outcomes are enhanced when therapists offer less directive treatments to high-reactance patients. The results revealed a large effect size ($d = .79$), confirming that highly reactant

						individuals did better in psychotherapy when the therapist assumed a reflective and nondirective stance than a directive and authoritative one. To a lesser degree, the opposite was also true. Limitations of the research and diversity considerations are noted. Practice recommendations are provided to minimize a patient's reactant behavior.

Bhattacharyya, Sriya; Park, Ellen Y.; Adler, Shelby; Saklad, Stephanie; Davis, Olivia		The crane project: Mixed-methods analysis of an expressive art therapy intervention to promote collective healing during the COVID-19 pandemic	Traumatology			Across the globe, societies have experienced devastating losses during the COVID-19 pandemic. Due to social distancing guidelines, funerals and other forms of commemoration were put on pause. In response to the lack of ability to honor lives and the need for personal and collective healing, a team came together and formed the Crane Project—an expressive art therapy intervention to help the community process grief and foster resilience in the form of a public art exhibit. Specifically, through workshops, individuals were encouraged to write six-word poems to describe their COVID-19 experience and create a paper crane for display with their poem inside. In total, 457 individuals created 514 poems. Using a mixed-methods study design, researchers analyzed participants' six-word poems and changes in subjective units of distress scores (SUDS) before and after the intervention. We found statistically significant decreases in mean SUDS in the full sample and within each intervention group; however, no statistically significant between group differences were found. Poems were also qualitatively coded into four main themes: (a) grief, loss, and challenges; (b) painful emotions; (c) gratitude, resilience, and hope; and (d) connection and community. Our

							quantitative and qualitative findings highlight the importance of arts-based experiential projects in processing the grief and loss experienced by individuals, as well as the critical importance of fostering hope, healing, and community in the face of tragedy. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Biancalani, Gianmarco; Orkibi, Hod; Keisari, Shoshi; Guglielmin, Maria Silvia; Bertagna, Giuseppe; Meola, Patrizia; Viezzoli, Davide; Finco, Nicoletta; Testoni, Ines	2022	Italian adolescents' perception of tele-psychodrama treatment during the COVID-19 Pandemic	Arts & health			1-14	BACKGROUND: Psychodrama is an experiential group psychotherapy that is used to enhance adolescents' wellbeing. The COVID-19 pandemic forced the adaptation of this method to an online setting. OBJECTIVE: This qualitative study investigated whether and how tele-psychodrama provides psychological support to adolescents, in order to better understand its strengths and weaknesses. PARTICIPANTS: 14 adolescents from Northern and Central Italy. METHOD: 14 interviews were conducted at the end of group tele-psychodrama treatment and were analysed with qualitative thematic analysis. RESULTS: Three themes were identified: (1) contribution of tele-psychodrama to adolescents' well-being; (2) implementation of psychodrama to the online setting; and (3) (the) shortcomings of tele-psychodrama. CONCLUSIONS: Despite the differences between online and in-person psychodrama, all the participants expressed their appreciation of group tele-psychodrama, which contributed to their overall psychological wellbeing and helped them process difficulties that emerged during the lockdowns.
Biben, Vitriana; Defi, Irma Ruslina; Surjadi, Elisa; Fajarulhuda, Muhammad;	2024	Influence of Personality on Geriatric Rehabilitation Outcomes in	Gerontology & geriatric medicine	10		2333721 4231220 831	Cauda Equina Syndrome (CES) becomes more common as the population ages, making diagnosis challenging and leading to underdiagnosis and poor management. Person-centered care is crucial for successful rehabilitation outcomes, and patient's personality influences it. Female, 77 years old, diagnosed with CES

Nurarifah, Sitti Ayu Hemas		Cauda Equina Syndrome Case				<p>caused by nucleus pulposus herniation at fourth to fifth lumbar vertebrae, with a complication of pressure injury grade IV due to immobilization. Her family's lack of caregiving skills, poverty, and histrionic personality disorder were her barriers to comply to rehabilitation program. Adding a psychotherapy based on personality on rehabilitation program increased her functional outcome. This case highlight the significance of assessing each patient's personality to optimize outcomes, emphasizing the importance of tailoring rehabilitation programs to individual needs, including psychosocial and environmental factors.</p>

<p>Binder, Annette; Hanke, Sara; Petersen, Kay Uwe; Huber, Clara; Banabak, Meryem; Preiser, Christine; Batra, Anil</p>	<p>2021</p>	<p>Opinions on Alcohol Consumption During Pregnancy and The Role of The Medical Staff as an Expert in This Regard - A Grounded Theory Analysis of Online Forum Discussions</p>	<p>Zeitschrift fur Geburtshilfe und Neonatologie</p>	<p>225</p>	<p>3</p>	<p>216-225</p>	<p>BACKGROUND: Alcohol consumption during pregnancy carries many risks for the unborn child. Despite preventive measures, some pregnant women consume alcohol. The aim of this study is to identify possible reasons for consumption during pregnancy and also to shed light on the attribution of an expert role to medical professionals by those affected. METHODS: In this study, 9 discussion threads from online forums on the topic of alcohol consumption during pregnancy with a total of 115 discussion participants were analyzed using grounded theory. The discursive validation of the results took place in the research team. RESULTS: It turned out that the individual definition of the mother role has an influence on consumer behavior. Women who are very concerned about the child's well-being occasionally used alcohol in stressful situations or on social occasions, but often reported a guilty conscience after the consumption. Women who gave more weight to their own needs were more likely to consume for pleasure or because they felt they were being patronized by prohibitions. An equitable doctor-patient relationship and detailed, non-directive information were identified as beneficial factors for ascribing the expert role to the gynecologist. On the other hand, a paternalistic attitude and the issuing of bans proved to be a hindrance. DISCUSSION: All women showed a high need for information about alcohol consumption during pregnancy. The doctor-patient relationship seems to play an important role in conveying information. In addition, it became clear that the desire for support in women striving for abstinence is not being sufficiently fulfilled. CONCLUSION: Alcohol consumption during pregnancy should be addressed regularly in the care of all pregnant women. In addition to information on</p>
--	-------------	--	--	------------	----------	----------------	---

							consumption risks, information on support offers is relevant.
Binder, Ute; Binder, Hans J.	2018	Klientenzentrierte Psychotherapie bei schweren psychischen Störungen. Neue Handlungs- und Theoriekonzepte zur Veränderung					Es wird ein Konzept der Anwendung klientenzentrierter Psychotherapie bei psychisch schwer gestörten Personen vorgestellt. Dazu wird ein dynamisches Persönlichkeitsmodell entwickelt, das in eine Neuinterpretation des therapeutischen Prozesses mündet. Schlüsselbegriffe des Konzepts sind die Konstrukte "Intensität", "Power" und "Commitment" als Erlebnisqualitäten in der interpersonellen Interaktion. - Aus dem Inhaltsverzeichnis: (1) Versuche zu Alternativüberlegungen zu Personmodellen. (2) Dynamisches Veränderungskonzept Intensität. (3) Power als Sicherheitskonzept. (4) Commitment als Beziehungskonzept.
Binder, Ute; Binder, Johannes	2019	Studien zu einer strungsspezifischen klientenzentrierten Psychotherapie. Bird, Brian M.; Jonnson, Melissa R.	2020	Have a seat: Supervisee perspectives on using chair-based role plays in clinical supervision		30	1	<p>Research indicates that supervision plays a critical role in the training of clinical psychologists. Nevertheless, there remain important gaps in our understanding of how particular supervision techniques are implemented, and how such techniques impact supervisees on their path to professional practice. This article presents two case illustrations demonstrating how the use of chair-based role plays in supervision can positively influence a supervisee's therapeutic confidence and empathy, and can foster the processing of emotional blocks, all of which have implications for practice. We support the illustrations with literature on the use of chair work in emotion-focused therapy and mindfulness-based role play, and we conclude with some limitations and cautions about role plays in supervision, along with recommendations for future research in the area. (PsycINFO Database Record (c) 2020 APA, all rights reserved)</p>

Bird, Joanna; Caligor, Eve	2024	A case report of the treatment of narcissistic personality disorder with transference focused psychotherapy	Journal of clinical psychology				The following case study provides a description of the transference-focused psychotherapy (TFP) treatment of a young man diagnosed with narcissistic personality disorder (NPD). TFP is an individual, psychodynamic therapy developed to treat a range of personality disorders. TFP is evidence-based for the treatment of borderline personality disorder and has been adapted for the treatment of NPD. This case illustrates the application of the strategies and techniques of TFP to treatment of NPD as well as challenges clinicians may face in arriving at timely diagnosis of the disorder. Although no specific treatment for NPD has been empirically validated, TFP utilizes the therapeutic techniques identified across modalities for successful treatment of pathological narcissism. This report describes how treatment interventions such as goal setting, developing a therapeutic alliance, using a treatment contract and addressing treatment interfering behaviors contributed to this patient's improvement in self-reflection, formation of healthier and more flexible ideas about self and other, increased self-agency, tolerance of normative disillusionments and increase in empathy.
Bird, Timothy; Mansell, Warren; Wright, Jason; Gaffney, Hannah; Tai, Sara	2018	Manage Your Life Online: A Web-Based Randomized Controlled Trial Evaluating the Effectiveness of a Problem-Solving Intervention in a Student Sample	Behavioural and cognitive psychotherapy	46	5	570–582	BACKGROUND: Evidence for the efficacy of computer-based psychological interventions is growing. A number of such interventions have been found to be effective, especially for mild to moderate cases. They largely rely on psychoeducation and 'homework tasks', and are specific to certain diagnoses (e.g. depression). AIMS: This paper presents the results of a web-based randomized controlled trial of Manage Your Life Online (MYLO), a program that uses artificial intelligence to engage the participant in a conversation across any problem topic. METHOD: Healthy volunteers (n = 213) completed a

							<p>baseline questionnaire and were randomized to the MYLO program or to an active control condition where they used the program ELIZA, which emulates a Rogerian psychotherapist. Participants completed a single session before completing post-study and 2-week follow-up measures. RESULTS: Analyses were per protocol with intent to follow-up. Both programs were associated with improvements in problem distress, anxiety and depression post-intervention, and again 2 weeks later, but MYLO was not found to be more effective than ELIZA. MYLO was rated as significantly more helpful than ELIZA, but there was no main effect of intervention on problem resolution. CONCLUSIONS: Findings are consistent with those of a previous smaller, laboratory-based trial and provide support for the acceptability and effectiveness of MYLO delivered over the internet for a non-clinical sample. The lack of a no-treatment control condition means that the effect of spontaneous recovery cannot be ruled out.</p>
<p>Bird, Victoria Jane; Sajun, Sana Zehra; Pepl, Renata; Evans-Lacko, Sara; Priebe, Stefan; Singh, Swaran; Venkatraman, Lakshmi; Ramachandran, Padmavati; Pasha, Aneeta;</p>	2023	<p>Assessing the effectiveness and cost-effectiveness of a solution-focused resource-orientated approach (DIALOG+) to improving the quality of life for people with psychosis in</p>	Trials	24	1	59	<p>BACKGROUND: Severe mental illness (SMI) presents a major challenge worldwide, affecting approximately 5-8% of the world's population. It causes significant distress to affected people, families and wider communities, generating high costs through loss of productivity and ongoing healthcare use. Over 75% of patients with psychosis receive inadequate care and experience a negative financial impact and reduced quality of life (QoL). It is therefore a priority to reduce the treatment gap by providing low-cost, effective interventions for people with psychosis. Our research project, PIECEs, is designed to explore, adapt and test a low-cost, approach (DIALOG+) that makes use of existing resources to improve community-based care for patients with</p>

Malik, Ashar; Qureshi, Onaiza		India and Pakistan-a cluster RCT					<p>psychosis. The research will be conducted in two urban sites: Karachi, Pakistan and Chennai, India. DIALOG+ is a novel, technology-assisted and resource-oriented intervention, based on QoL research, concepts of patient-centred communication, IT developments and solution-focused therapy. However, the approach has not been rigorously tested within India and Pakistan. Our randomised controlled trial (RCT) aims to test the effectiveness and cost-effectiveness of DIALOG+ in improving the QoL and clinical outcomes for individuals with long-term psychosis being treated in the community in India and Pakistan. METHODS: To assess the acceptability, feasibility, and cost effectiveness of DIALOG+, we will conduct a cluster RCT with 210 patients and 14 clinicians in each country. The intervention will be used during a routine interaction between a clinician and a patient. It consists of a patient-centred assessment (the DIALOG scale) whereby the clinician invites the patient to rate their satisfaction with different life domains and treatment aspects, which forms the active control group. The intervention group will follow this up with a four-step solution-focused approach to identify the patient's resources and develop solutions to deal with the patient's concerns (DIALOG+). DISCUSSION: If shown to be effective DIALOG+ has the potential to improve community-based care and the QoL for millions of people within India and Pakistan who experience psychosis. TRIAL REGISTRATION: The trial was registered prospectively on the ISRCTN Registry: ISRCTN13022816 on 9 February 2022.</p>
Birt, Julia; Thacher, Abigail; Steinberg,	2023	Effectiveness of DBT skills training in	Psychological Services		19 39- 14	122-129	A plethora of research highlights the effectiveness of dialectical behavioral therapy (DBT) in improving emotion regulation and psychological functioning

Hannah; Weiler, Rachel; Poplawski, Rebecca; Dobbs-Marsh, Jasmine; Robinson, Athena; Zack, Sanno		outpatient men: A naturalistic study			8X(Electronic), 15 41-15 59(Print)		transdiagnostically. However, the majority of this research has focused on women, and the limited existing research on men has concentrated on high acuity patients in forensic and inpatient settings. The present study examined the effectiveness of DBT skills groups in reducing emotion regulation difficulties in a transdiagnostic sample of adult men in a university-based clinical outpatient setting using a naturalistic design. Sixteen adult male patients completed self-report measures examining emotion regulation difficulties (Difficulties in Emotion Regulation Scale) at intake and following one 12-week module of DBT skills group. Men showed a significant reduction in overall difficulty regulating emotions with a moderate effect size ($d = 0.63$, $p = 1.06$, $N = 82$) showed significant improvements in global emotion regulation difficulties ($d = 0.71$, $p < .01$), with marked improvement across all six subscales. Implications of findings for the application of DBT for men in outpatient settings is discussed, limitations reviewed, and areas for future research suggested. Bischkopf, Jeannette	2016	Emotion-focused therapy					
Bischkopf, Jeannette; Tatschner, Marianne	2022	(Selbst-)Stigmatisierung erkennen, verstehen und berwinden	Verhaltenstherapie und psychosoziale Praxis	54	2	259–270	(Selbst-)Stigmatisierung hat vielfltige Auswirkungen, die sich z. B. als Gefhle von Scham, Minderwertigkeit, Ohnmacht, besonderer Verletzlichkeit und Hoffnungslosigkeit zeigen knnen. Im Beitrag werden die Entwicklung und Auswirkungen der (Selbst-)Stigmatisierung vor allem auf die Entstehung von Scham diskutiert. Es wird auf die Emotionsfokussierte Therapie nach Greenberg et al. sowie die Broaden- und Build-Theorie positiver Emotionen nach Fredrickson Bezug genommen. Anschlieend werden vier Mglichkeiten

						<p>aufgezeigt, die zur Berwindung von Scham und (Selbst-) Stigmatisierung beitragen und in Beratung und Therapie genutzt werden können. Ein besonderer Fokus wird dabei auf Achtsamkeit und Selbstmitgefühl gelegt. Gerade im Umgang mit negativen Selbst-Zuschreibungen bieten sie beachtenswerte neue Möglichkeiten und eröffnen Wege aus der Selbst-Stigmatisierung. Nicht die Veränderung von Gedankeninhalten steht dabei im Vordergrund, sondern eine neue Art der Zuwendung zu den Gedanken und zu der Person, die diese Gedanken hat.</p>
Bitzer-Gavornik, Gnther	2016	Lebens- und Sozialberatung in sterreich				<p>Die Entwicklung und die aktuelle Situation der Lebens- und Sozialberatung in sterreich wird beschrieben. Lebens- und Sozialberatung umfasst die professionelle, bewusste und geplante Beratung, Betreuung und Begleitung von Menschen in Entscheidungs- und Problemsituationen. Praxisfelder und Anwendungsbereiche wie etwa Persönlichkeitsberatung, Paarberatung, Familienberatung, geschlechtsspezifische Beratung, Coaching, Mediation, Burnoutprophylaxe und Suchtberatung werden aufgezeigt. Darüber hinaus werden Methoden der Lebensberatung beschrieben, die in sterreich praktiziert werden, etwa klientenzentrierte Beratung, systemische (Familien-)Beratung und Integrative Gestaltberatung. Bjerck-Amundsen, Freja; Opsahl, Tobias; Emiliussen, Jakob	2022	The interaction between good life conceptions and psychotherapeutic practice - an interpretative phenomenological study of psychologists' experiences	Scandinavian J Psychology (Scandinavian Journal of Psychology)	63	1	8-18	<p>Based on qualitative interviews with four Danish psychologists and employing Interpretative Phenomenological Analysis (IPA), this study explored psychologists' understandings about the good life and how these influence the participants' clinical practice. The study found that the participants were quite aware of how their conceptions of the good life play a role in their work. Good life understandings that influenced therapeutic practice were quite similar amongst participants and were largely characterized by traits often associated with good mental health. Themes identified</p>

							<p>were: "Everyday well-being," "presence", and "taking care of oneself and others," and subthemes were "contact with the self," "awareness of the good things in life," "connectedness," "to mean something to others," "coping with distress," and "compassion for oneself and others." Among participants, these good life conceptions had a similar influence on different areas of their practice in terms of how the participants understand their clients' issues, which impacted what they talk to their clients about, and what they seek to achieve with the clients in therapy. Therefore, the good life conceptions influenced the methods, techniques, personal behaviors, and therapeutic approaches used to provide good and effective therapy. Another finding was that participants' clinical experiences also seemed to impact their good life conceptions. The interpretation of the participants' experiences represented a hermeneutic model suggesting that the participants' good life conceptions and their clinical practice experiences might inform and reinforce each other in a continuously expanding overlap. The actual nature of this interaction and its implications are relevant for future research.</p>
Black, Isra; Helgason, Ásgeir Rúnar	2018	Using motivational interviewing to facilitate death talk in end-of-life care: an ethical analysis	BMC palliative care	17	1	51	<p>BACKGROUND: Morbidity arising from unprepared bereavement is a problem that affects close personal relations of individuals at the end-of-life. The bereavement studies literature demonstrates that a lack of preparedness for a loved one's death is a risk factor for secondary psychological morbidity among survivors. Short awareness time of death negatively correlates to preparedness for bereavement. The absence of disclosure of end-of-life diagnosis and prognosis to close personal relations ('death talk') between patients and loved ones, or health professionals and loved ones, may</p>

							<p>contribute to short awareness time of death. To increase awareness time of death, we might attempt to increase patient first-personal disclosure of end-of-life diagnosis and prognosis to loved-ones, and/or patient consent to health professional disclosure of the same. MAIN TEXT: Interventions based on motivational interviewing in end-of-life care whose aim is to facilitate death talk, either by the patient directly, or by a health professional with the patient's consent, may offer a part solution to the problem of unprepared bereavement. This paper evaluates the ethical permissibility of such interventions. We consider two ethical objections to using motivational interviewing in this way: first, that it is inappropriate for practitioners to seek disclosure as an outcome in this setting; second, that aiming at disclosure risks manipulating individuals into death talk. While it need not be impermissible to direct individuals toward disclosure of end-of-life diagnosis/prognosis, the objection from manipulation implies that it is pro tanto ethically preferable to use motivational interviewing in a non-directive mode in death talk conversations. However, insofar as non-directive motivational interviewing requires more advanced skills, and thus may be more difficult to learn and to practise, we advance that it may be ethically permissible, all things considered, to employ directional, or specific outcome-oriented, motivational interviewing. CONCLUSION: Motivational interviewing interventions in end-of-life care whose aim is to facilitate death talk, either by the patient directly, or by a health professional with the patient's consent may be ethically permissible, all things considered.</p>
Blackwell, Christopher W.	2020	Demonstrating Nursing	Journal of transcultural	31	2	209–215	Introduction: Human Rights Campaign annually scores health care treatment of lesbian, gay, bisexual,

		Excellence Through Equality: The Relationship Between Magnet® Status and Organizational LGBTQ Client Services and Support	nursing : official journal of the Transcultural Nursing Society				transgender, and queer (LGBTQ) employees and clients among four measured dimensions in its Healthcare Equality Index (HEI). The purpose of this study was to determine if the score organizations earned on the 2018 HEI dimension measuring LGBTQ client services and support correlated with organizations' American Nurses Credentialing Center Magnet® recognition status, a distinction of nursing excellence. Method: Using a secondary data analysis approach, data obtained from Human Rights Campaign that specifically rated LGBTQ client services and support in 2018 HEI participating organizations (n = 626) were compared with the most recent inventory of American Nurses Credentialing Center Magnet health care organizations (n = 477). Results: LGBTQ client services and support HEI scores positively correlated with Magnet status (p = .0002). Discussion: Provision of LGBTQ client services and Magnet recognition is strongly related to higher quality nursing care, suggesting organizations earning Magnet recognition provide more equitable services to its LGBTQ clients.
Bland, Andrew M.	2018	Facilitating and assessing personal growth in helper development using Hart's (2014) Four Virtues	The Humanistic Psychologist	46	1	6-29	During the last decade, calls have been made for a paradigm shift in the training of helping professionals to include an increased emphasis on developing the helper as a person in addition to honing technical proficiency. Models by Ridley et al. (2011), Geller and Greenberg (2012), and Fauth et al. (2007) have identified characteristics and provided working definitions of intrapersonal helper competencies and attributes. However, these are only a descriptive starting point. More work remains in their practical implementation in helper training and research thereupon, as well as in developing appropriate tools for assessing helpers' capacities in

							these areas. One exception to this dearth of helper-as-person assessment tools is Hart and Hart's (2014) Spiritual Assessment Matrix (SAM)—which is based on Hart's (2014) Four Virtues, a model of personal growth that encourages balance among the 4 interdependent qualities of presence, heart, wisdom, and creation. In this article, I reflect upon my employment of Hart's model and the SAM to promote intrapersonal and interpersonal competence in master's students enrolled in an entry-level graduate course in Psychotherapy and Intervention Skills. After surveying Hart's model, I describe the method by which the students completed and reflected upon the results of the SAM before and after supervised experience with a client. Next, I provide a thematic analysis of the students' end-of-semester reflections with connections made to extant helper development literature. Finally, I discuss implications of Hart's model and assessment for helper training while addressing its limitations and provide suggestions for further research. Blaschke, Sarah; O'Callaghan, Clare C.; Schofield, Penelope	2020	Nature-based supportive care opportunities: a conceptual framework	BMJ supportive & palliative care	10	1	36–44	OBJECTIVE: Given preliminary evidence for positive health outcomes related to contact with nature for cancer populations, research is warranted to ascertain possible strategies for incorporating nature-based care opportunities into oncology contexts as additional strategies for addressing multidimensional aspects of cancer patients' health and recovery needs. The objective of this study was to consolidate existing research related to nature-based supportive care opportunities and generate a conceptual framework for discerning relevant applications in the supportive care setting. METHODS: Drawing on research investigating nature-based engagement in oncology contexts, a two-step analytic

						<p>process was used to construct a conceptual framework for guiding nature-based supportive care design and future research. Concept analysis methodology generated new representations of understanding by extracting and synthesising salient concepts. Newly formulated concepts were transposed to findings from related research about patient-reported and healthcare expert-developed recommendations for nature-based supportive care in oncology. RESULTS: Five theoretical concepts (themes) were formulated describing patients' reasons for engaging with nature and the underlying needs these interactions address. These included: connecting with what is genuinely valued, distancing from the cancer experience, meaning-making and reframing the cancer experience, finding comfort and safety, and vital nurturance. Eight shared patient and expert recommendations were compiled, which address the identified needs through nature-based initiatives. Eleven additional patient-reported recommendations attend to beneficial and adverse experiential qualities of patients' nature-based engagement and complete the framework. CONCLUSIONS: The framework outlines salient findings about helpful nature-based supportive care opportunities for ready access by healthcare practitioners, designers, researchers and patients themselves.</p>
Bleiberg, Kathryn L.; Markowitz, John C.		Interpersonal psychotherapy for PTSD: Treating trauma without exposure	Journal of Psychotherapy Integration	29	1	<p>Interpersonal psychotherapy (IPT) is a time-limited, diagnosis-targeted psychotherapy originally developed for the treatment of major depression. Research studies have repeatedly demonstrated its efficacy in treating mood disorders and other psychiatric disorders over the past 40 years. Because IPT is a life event-based treatment that focuses on improving interpersonal functioning, it seemed natural to adapt it for the</p>

							treatment of posttraumatic stress disorder (PTSD), a life event-based illness that affects interpersonal functioning. Preliminary data have suggested that the efficacy of IPT in alleviating PTSD symptoms is equal to that of prolonged exposure, the best tested exposure-based treatment. We describe the principles of IPT and its modifications for treating PTSD. A case illustration describes a patient with PTSD related to military trauma. The authors discuss their reluctance to integrate IPT for PTSD with other psychotherapeutic perspectives. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Blob, Friedgard	2018	Das "Nein" in der Prsenz - Grenzen setzen durch ganzkörperliche Anwesenheit	Gesprächspsychotherapie und Personzentrierte Beratung	49	4	212-216	Reflektiert wird über das vorsprachliche und auf körperlicher Ebene angelegte Ur-Nein und den Nutzen von positiven Grenzziehungen in alltäglichen Interaktionen. Anhand grundlegender Konzepte des Focusing und der Leibpsychotherapie werden körperlich basierte Abgrenzungsprozesse dargelegt, therapeutische Zugänge aufgezeigt und deren Bedeutung für den Alltag herausgearbeitet.
Blonigen, Daniel M.; Rodriguez, Allison L.; Manfredi, Luisa; Nevedal, Andrea; Rosenthal, Joel; McGuire, James F.; Smelson, David; Timko, Christine	2018	Cognitive-behavioral treatments for criminogenic thinking: Barriers and facilitators to implementation within the Veterans Health Administration	Psychological Services	15	1		Cognitive-behavioral treatments for criminogenic thinking (i.e., antisocial cognitions, attitudes, and traits) are regarded as best practices for reducing criminal recidivism among justice-involved adults. However, the barriers and facilitators to implementation of these treatments within large health care systems such as the Veterans Health Administration (VHA) are largely unknown. To address this gap, we conducted qualitative interviews with 22 Specialists from the VHA's Veterans Justice Programs who had been trained in a cognitive-behavioral treatment for criminogenic thinking (i.e., Moral Reconciliation Therapy [MRT], Thinking for a Change [T4C]). The time-intensiveness of these treatments emerged as a

						<p>barrier to implementation. Potential solutions identified were patient incentives for treatment engagement, streamlining the curriculum, and implementing the treatments within long-term/residential programs. At the program level, providers' stigma/bias toward patients with antisocial tendencies was seen as a barrier to implementation, as were time/resource constraints on providers. To address the latter, use of peer providers to deliver the treatments and partnerships between justice programs and behavioral health services were suggested. At the system level, lack of recognition of criminogenic treatments as evidence based, and uncertainty of sustained funds to support ongoing costs of these treatments emerged as implementation barriers. To address the latter, a train-the-trainers model was suggested. Our findings serve as a guide for implementation of criminogenic treatments for providers and policymakers in VHA and other large health care systems, which are increasingly called upon to provide care to justice-involved adults in the community. <p>Bodenmann, Guy; Kessler, Mirjam; Kuhn, Rebekka; Hocker, Lauren; Randall, Ashley K.</p>	<p>2020</p>	<p>Cognitive-behavioral and emotion-focused couple therapy: Similarities and differences</p>	<p>Clinical Psychology in Europe, 2020</p>				<p>Background: Couples and families often seek therapy to deal with relational distress, which is a result of external or internal factors of the relationship. Two approaches are acknowledged to be most effective in dealing with relationship distress or psychological disorders in couples: (1) cognitive behavioral couple therapy with new directions (CBCT) and (2) emotion-focused couple therapy (EFCT). In this article we investigate how much CBCT and EFCT really differ with regard to working with emotions, which is claimed to be a major focus of EFCT, and whether there exist significant differences in efficacy between these two approaches. Method: This article critically reviews the theoretical background, process, techniques and outcomes associated with CBCT and EFCT in an effort to challenge the assumptions noted above. Results: There is no evidence that EFCT is more emotion-focused than CBCT. Both approaches were repeatedly examined with RCT studies with follow-ups. In sum, no significant differences in effect size were found between CBCT and EFCT. Conclusion: CBCT and EFCT are both effective in reducing couples' distress.</p>
<p>Boeckh, Albrecht</p>	<p>2019</p>	<p>Die Rolle der Gefhle in der Gestalttherapie</p>					<p>In einer Errterung der Rolle der Gefhle in der Gestalttherapie wird zunchst auf die Phnomenologie der Gefhle eingegangen. Die Ausfhrungen beziehen sich dabei unter anderem auf negative und positive Gefhle, pathische und aktivierende Gefhle, primre und sekundre Gefhle, groe und kleine Gefhle, Abwesenheit und Abwehr von Gefhlen, Gefhlsklte, den ganzheitlichen Charakter gefhlsmigen Erlebens und gefhlsbestimmten Handelns, Gefhle als Zentren des Wandels, Gefhlsparitten, Empathie, Gefhle der anderen als Teil des eigenen Erlebens. Boecking, Benjamin; Brueggemann, Petra; Rose, Matthias; Mazurek, Birgit	2023	Chronic tinnitus: An interplay between somatic and psychological factors	HNO	71	11	719-730	Chronic tinnitus is a common, sometimes highly distressing phenomenon that can be triggered and maintained by an interplay of physical and psychological factors. Partnering with clinical psychology and psychosomatic medicine, modern otolaryngology integrates both medical (e.g., hearing loss) and psychological influences (e.g., interactions between biographical experiences, personality traits, subjective evaluation of intrapsychic and interpersonal stimuli, emotional states, and intrapsychic or interpersonal emotion regulation strategies). Both groups of variables can influence the intensity and course of chronic tinnitus symptomatology both directly and indirectly, whereby the quality and relative degrees of psychological and physical components in a person's self-experience can fluctuate. With this in mind, the present article distinguishes between chronic tinnitus symptomatology with or without hearing loss-and strongly advocates for an integrated understanding of the symptomatology within a holistic psychological frame of reference. After a brief introduction to the principles of psychosomatic medicine and psychotherapy, the article discusses psychological case conceptualization using a vulnerability-stress-coping (VSC) model as an example, outlines clinical aspects and diagnostics of chronic tinnitus

							symptomatology, and concludes with a conceptualization of chronic tinnitus-related distress as a function of person-centered VSC interactions.
Boelen, Paul A.; Lenferink, Lonneke I. M.; Spuij, Mariken	2021	CBT for Prolonged Grief in Children and Adolescents: A Randomized Clinical Trial	The American journal of psychiatry	178	4	294–304	<p>OBJECTIVE: Prolonged grief disorder was newly included in ICD-11 and resembles persistent complex bereavement disorder, newly included in DSM-5. Although prolonged grief disorder in adults can be successfully treated by cognitive-behavioral therapy (CBT), there is no evidence yet that CBT interventions can successfully alleviate the disorder in children and adolescents. The goal of this randomized clinical trial was to examine the effects of a CBT program, CBT Grief-Help, for prolonged grief disorder in children and adolescents in comparison with the effects of nondirective supportive counseling. METHODS: A total of 134 children and adolescents with prolonged grief disorder (mean age, 13.10 years [SD=2.84], bereaved a mean of 37.79 months [SD=36.23] earlier) were randomly assigned to receive either CBT Grief-Help (N=74) or supportive counseling (N=60). Both treatment conditions encompassed nine individual sessions with children and adolescents paralleled by five counseling sessions with parents or caretakers. Children and adolescents completed measures of prolonged grief disorder, depression, and posttraumatic stress disorder (PTSD), and their parents or caretakers completed measures of their children's problem behavior before treatment, immediately after treatment, and 3, 6, and 12 months after treatment. RESULTS: Both treatments yielded moderate to large effect sizes across prolonged grief disorder and most other outcome measures. Compared with supportive counseling, CBT Grief-Help resulted in significantly greater reductions in prolonged grief disorder symptoms</p>

						at all posttreatment assessments, and it was more successful in alleviating depression, PTSD symptoms, and internalizing problems 6 and 12 months after treatment. CONCLUSIONS: Prolonged grief disorder and its symptoms in bereaved children and adolescents can be effectively treated by CBT interventions. The superior long-term effects of CBT Grief-Help relative to supportive counseling suggest that this treatment successfully strengthens children and adolescents in facing challenges brought about by bereavement.
Bogart, Laura M.; Phaladze, Nthabiseng; Kgotlaetsile, Keonayang; Klein, David J.; Goggin, Kathy; Mosepele, Mosepele	2023	Pilot Test of Mopati, a Multi-Level Adherence Intervention for People Living with HIV and Their Treatment Partners in Botswana	International journal of behavioral medicine			BACKGROUND: Low-cost, scalable strategies are necessary to reach the UNAIDS 2030 target of ending HIV as a public health threat. Use of treatment partners, informal caregivers selected by people living with HIV to support antiretroviral therapy adherence, is one such strategy that is included in many countries' HIV guidelines, including Botswana, a country with high HIV prevalence. METHOD: From June 2021 to June 2022, we pilot tested a clinic-based treatment partner intervention ("Mopati"), including standardized language for providers to guide patients on treatment partner selection and workshops to train treatment partners on providing non-directive support to patients using a non-confrontational, non-judgmental approach. Sixty unsuppressed patients (30 per clinic) and 45 treatment partners (17 intervention, 28 control) were recruited from an intervention-control clinic matched-pair in Gaborone, Botswana. RESULTS: Mopati had medium-to-large effects on increasing patients' adherence, adherence self-efficacy, intrinsic adherence motivation, and perceived non-directive support from treatment partners, and decreasing treatment partner caregiver burden. Aggregate viral suppression rates significantly increased in the

							intervention (vs. control) clinic. Qualitative data from 14 clinic staff, 21 patients, and 16 treatment partners indicated that Mopati was viewed as effective. Providers said the guidance empowered them to be proactive in communicating about adherence; most reported using the guidance. CONCLUSION: This study shows preliminary support for the use of treatment partners in HIV care, and further evidence for interventions that leverage patients' existing support. This research can inform ways to improve adherence to HIV treatment as well as the treatment of HIV-related comorbid conditions in lower-resource settings. TRIAL REGISTRATION: ClinicalTrials.gov Identifier: NCT04796610.
Boico, Vasile; Humblestone, Susan; Moutoussis, Michael; Selai, Caroline	2023	Group psychotherapy format guided self-help for patients with FNSD awaiting inpatient multidisciplinary treatment: A pilot study	Couns and Psychother Res (Counselling and Psychotherapy Research)				
Bonfils, Kelsey A.; Dreison, Kimberly C.; Luther, Lauren; Fukui, Sadaaki; Dempsey, Abigail E.; Rapp, Charles A.; Salyers, Michelle P.	2018	Implementing CommonGround in a community mental health center: Lessons in a computerized decision support system	Psychiatric Rehabilitation Journal	41	3		Objective: Although shared decision making (SDM) is a key element of client-centered care, it has not been widely adopted. Accordingly, interventions have been developed to promote SDM. The aim of this study was to explore the implementation process of one SDM intervention, CommonGround, which utilizes peer specialists and a computerized decision support center to promote SDM. Method: As part of a larger study, CommonGround was implemented in 4 treatment teams in a community mental health center. The

							<p>implementation process was examined by conducting semistructured interviews with 12 staff members that were integral to the CommonGround implementation. Responses were analyzed using content analysis. Program fidelity and client program use were also examined. Results: Although key informants identified several client and staff benefits to using CommonGround, including improved treatment engagement and availability of peer specialists, most clients did not use CommonGround consistently throughout the implementation. Key informants and fidelity reports indicated a number of program (e.g., technological difficulties, increased staff burden) and contextual barriers (e.g., poor fit with service structure, decision support center location, low staff investment and high turnover) to the successful implementation of CommonGround. Strategies to maximize the implementation by increasing awareness, buy-in, and utilization are also reported. Conclusions and Implications for Practice: This implementation of CommonGround was limited in its success partly as a result of program and contextual barriers. Future implementations may benefit from incorporating the strategies identified to maximize implementation in order to obtain the full program benefits. Bonnet, Udo; Winter, Elena	2020	"Internetbasierte Verfahren können die Hoffnung auf den Therapieerfolg verstärken"	Gesprächspsychotherapie und Personenzentrierte Beratung	51	1	17-18	Die Digitalisierung hat enormen Einfluss auf unser Kommunikationsverhalten und auf die Art unserer Beziehungsgestaltung. Dabei führen die neuen Medien und die immer verfügbare "Online-Welt" im realen Leben oft in die soziale Isolation. Aber sie bergen auch neue Möglichkeiten für Hilfsangebote: Prof. Dr. med. Udo Bonnet, Chefarzt der Klinik für Psychiatrie, Psychotherapie und Psychosomatik am Evangelischen Krankenhaus in Castrop-Rauxel, spricht in einem Interview über PC-gestützte Psychotherapie bei depressiven Patienten am Beispiel des Online-Therapieprogramms Deprexis.
Boritz, Tali; Barnhart, Ryan; Angus, Lynne; Constantino, Michael J.	2017	Narrative flexibility in brief psychotherapy for depression	Psychotherapy research : journal of the Society for Psychotherapy Research	27	6	666-676	OBJECTIVE: This study aimed to further understand how narrative flexibility contributes to therapeutic outcome in brief psychotherapy for depression utilizing the Narrative-Emotion Process Coding System (NEPCS), an observational measure that identifies specific markers of narrative and emotion integration in therapy sessions. METHOD: The present study investigated narrative

						flexibility by examining the contribution of NEPCS shifting (i.e., movement between NEPCS markers) in early, middle, and late sessions of client-centred therapy (CCT), emotion-focused therapy (EFT), and cognitive therapy (CT) and treatment outcome (recovered versus unchanged at the therapy termination). A logistic regression, with Wald tests of parameter estimates and pairwise comparisons, was used to test the study hypotheses. RESULTS: Results demonstrated that for recovered clients, the probability of shifting over the course of a therapy session was constant, whereas the probability of shifting declined for unchanged clients as the session progressed. There was also evidence that longer duration of time spent in any single NEPCS marker was negatively associated with shifting for both recovered and unchanged clients, although the effect was stronger for unchanged clients. CONCLUSIONS: The results provided preliminary support for the contribution of narrative flexibility to treatment outcomes in EFT, CCT, and CT treatments of depression.	
Bose, Deepika; Pettit, Jeremy W.; Silk, Jennifer S.; Ladouceur, Cecile D.; Olino, Thomas M.; Forbes, Erika E.; Siegle, Greg J.; Dahl, Ronald E.; Kendall, Phillip C.; Ryan, Neal D.; McMakin, Dana L.	2023	Therapeutic Alliance, Attendance, and Outcomes in Youths Receiving CBT or Client-Centered Therapy for Anxiety	Journal of clinical child and adolescent psychology : the official journal for the Society of Clinical Child and Adolescent Psychology, American Psychological Association, Division 53			1-11	OBJECTIVE: Positive associations between therapeutic alliance and outcome (e.g. youth symptom severity) have been documented in the youth anxiety literature; however, little is known about the conditions under which early alliance contributes to positive outcomes in youth. The present study examined the relations between therapeutic alliance, session attendance, and outcomes in youths (N = 135; 55.6% female) who participated in a randomized clinical trial testing the efficacy of cognitive-behavioral therapy or client-centered therapy for anxiety. METHOD: We evaluated a conceptual model wherein: (1) early alliance indirectly contributes to positive outcomes by improving session attendance; (2) alliance-outcome

							associations differ by intervention type, with stronger associations in cognitive-behavioral therapy compared to client-centered therapy; and (3) alliance-outcome associations vary across outcome measurement timepoints, with the effect of early alliance on outcomes decaying over time. RESULTS: Contrary to hypotheses, provider ratings of early alliance predicted greater youth-rated anxiety symptom severity post-treatment (i.e. worse treatment outcomes). Session attendance predicted positive youth-rated outcomes, though there was no indirect effect of early alliance on outcomes through session attendance. CONCLUSIONS: Results show that increasing session attendance is important for enhancing outcomes and do not support early alliance as a predictor of outcomes.
Bosgraaf, Liesbeth; Spreen, Marinus; Pattiselanno, Kim; van Hooren, Susan	2020	Art Therapy for Psychosocial Problems in Children and Adolescents: A Systematic Narrative Review on Art Therapeutic Means and Forms of Expression, Therapist Behavior, and Supposed Mechanisms of Change	Frontiers in psychology	11		584685	Background: Art therapy (AT) is frequently offered to children and adolescents with psychosocial problems. AT is an experiential form of treatment in which the use of art materials, the process of creation in the presence and guidance of an art therapist, and the resulting artwork are assumed to contribute to the reduction of psychosocial problems. Although previous research reports positive effects, there is a lack of knowledge on which (combination of) art therapeutic components contribute to the reduction of psychosocial problems in children and adolescents. Method: A systematic narrative review was conducted to give an overview of AT interventions for children and adolescents with psychosocial problems. Fourteen databases and four electronic journals up to January 2020 were systematically searched. The applied means and forms of expression, therapist behavior, supposed mechanisms of change, and effects were extracted and coded. Results: Thirty-seven studies out of

						<p>1,299 studies met the inclusion criteria. This concerned 16 randomized controlled trials, eight controlled trials, and 13 single-group pre-post design studies. AT interventions for children and adolescents are characterized by a variety of materials/techniques, forms of structure such as giving topics or assignments, and the use of language. Three forms of therapist behavior were seen: non-directive, directive, and eclectic. All three forms of therapist behavior, in combination with a variety of means and forms of expression, showed significant effects on psychosocial problems. Conclusions: The results showed that the use of means and forms of expression and therapist behavior is applied flexibly. This suggests the responsiveness of AT, in which means and forms of expression and therapist behavior are applied to respond to the client's needs and circumstances, thereby giving positive results for psychosocial outcomes. For future studies, presenting detailed information on the potential beneficial effects of used therapeutic perspectives, means, art techniques, and therapist behavior is recommended to get a better insight into (un)successful art therapeutic elements.</p>
<p>Bosnjak Kuharic, Dina; Kekin, Ivana; Hew, Joanne; Rojnic Kuzman, Martina; Puljak, Livia</p>	2019	Interventions for prodromal stage of psychosis	The Cochrane database of systematic reviews	2019	11	<p>BACKGROUND Psychosis is a serious mental condition characterised by a loss of contact with reality. There may be a prodromal period or stage of psychosis, where early signs of symptoms indicating onset of first episode psychosis (FEP) occur. A number of services, incorporating multimodal treatment approaches (pharmacotherapy, psychotherapy and psychosocial interventions), developed worldwide, now focus on this prodromal period with the aim of preventing psychosis in people at risk of developing FEP.</p>

						<p>OBJECTIVES The primary objective is to assess the safety and efficacy of early interventions for people in the prodromal stage of psychosis. The secondary objective is, if possible, to compare the effectiveness of the various different interventions.</p> <p>SEARCH METHODS We searched Cochrane Schizophrenia's study-based Register of studies (including trials registers) on 8 June 2016 and 4 August 2017.</p> <p>SELECTION CRITERIA All randomised controlled trials (RCTs) evaluating interventions for participants older than 12 years, who had developed a prodromal stage of psychosis.</p> <p>DATA COLLECTION AND ANALYSIS Review authors independently inspected citations, selected studies, extracted data, and assessed study quality.</p> <p>MAIN RESULTS We included 20 studies with 2151 participants. The studies analysed 13 different comparisons. Group A comparisons explored the absolute effects of the experimental intervention. Group B were comparisons within which we could not be clear whether differential interactive effects were also ongoing. Group C comparisons explored differential effects between clearly distinct treatments. A key outcome for this review was 'transition to psychosis'. For details of other main outcomes please see 'Summary of findings' tables. In Group A (comparisons of absolute effects) we found no clear difference between amino acids and placebo (risk ratio (RR) 0.48 95% confidence interval (CI) 0.08 to 2.98; 2 RCTs, 52 participants; very low-quality evidence). When</p>
--	--	--	--	--	--	--

						<p>omega-3 fatty acids were compared to placebo, fewer participants given the omega-3 (10%) transitioned to psychosis compared to the placebo group (33%) during long-term follow-up of seven years (RR 0.24 95% CI 0.09 to 0.67; 1 RCT, 81 participants; low-quality evidence). In Group B (comparisons where complex interactions are probable) and in the subgroup focusing on antipsychotic drugs added to specific care packages, the amisulpiride + needs-focused intervention (NFI) compared to NFI comparison (no reporting of transition to psychosis; 1 RCT, 102 participants; very low-quality evidence) and the olanzapine + supportive intervention compared to supportive intervention alone comparison (RR 0.58 95% CI 0.28 to 1.18; 1 RCT, 60 participants; very low-quality evidence) showed no clear differences between groups. In the second Group B subgroup (cognitive behavioural therapies (CBT)), when CBT + supportive therapy was compared with supportive therapy alone around 8% of participants allocated to the combination of CBT and supportive therapy group transitioned to psychosis during follow-up by 18 months, compared with double that percentage in the supportive therapy alone group (RR 0.45 95% CI 0.23 to 0.89; 2 RCTs, 252 participants; very low-quality evidence). The CBT + risperidone versus CBT + placebo comparison identified no clear difference between treatments (RR 1.02 95% CI 0.39 to 2.67; 1 RCT, 87 participants; very low-quality evidence) and this also applies to the CBT + needs-based intervention (NBI) + risperidone versus NBI comparison (RR 0.75 95% CI 0.39 to 1.46; 1 RCT, 59 participants; very low-quality evidence). Group C (differential effects) also involved six comparisons. The first compared CBT with supportive therapy. No clear difference was found for the 'transition</p>
--	--	--	--	--	--	---

						<p>to psychosis' outcome (RR 0.74 95% CI 0.28 to 1.98; 1 RCT, 72 participants; very low-quality evidence). The second subgroup compared CBT + supportive intervention was compared with a NBI + supportive intervention, again, data were equivocal, few and of very low quality (RR 6.32 95% CI 0.34 to 117.09; 1 RCT, 57 participants). In the CBT + risperidone versus supportive therapy comparison, again there was no clear difference between groups (RR 0.76 95% CI 0.28 to 2.03; 1 RCT, 71 participants; very low-quality evidence). The three other comparisons in Group C demonstrated no clear differences between treatment groups. When cognitive training was compared to active control (tablet games) (no reporting of transition to psychosis; 1 RCT, 62 participants; very low quality data), family treatment compared with enhanced care comparison (RR 0.54 95% CI 0.18 to 1.59; 2 RCTs, 229 participants; very low-quality evidence) and integrated treatment compared to standard treatment comparison (RR 0.57 95% CI 0.28 to 1.15; 1 RCT, 79 participants; very low-quality evidence) no effects of any of these approaches was evident.</p> <p>AUTHORS' CONCLUSIONS</p> <p>There has been considerable research effort in this area and several interventions have been trialled. The evidence available suggests that omega-3 fatty acids may prevent transition to psychosis but this evidence is low quality and more research is needed to confirm this finding. Other comparisons did not show any clear differences in effect for preventing transition to psychosis but again, the quality of this evidence is very low or low and not strong enough to make firm conclusions.</p> <p>پیشینه: سایکوز یک وضعیت روانی جدی است که با از دست دادن ارتباط با واقعیت شناخته می‌شود. ممکن است یک دوره هشدار دهنده (prodromal) یا</p>

Bossarte, Robert M.; Kessler, Ronald C.; Nierenberg, Andrew A.; Chattopadhyay, Ambarish; Cuijpers, Pim; Enrique, Angel; Foxworth, Phyllis M.; Gildea, Sarah M.; Belnap, Bea Herbeck; Haut, Marc W.; Law, Kari B.; Lewis, William D.; Liu, Howard; Luedtke, Alexander R.; Pigeon, Wilfred R.; Rhodes, Larry A.; Richards, Derek; Rollman, Bruce L.; Sampson, Nancy A.; Stokes, Cara M.; Torous, John; Webb, Tyler D.;	2022	The Appalachia Mind Health Initiative (AMHI): a pragmatic randomized clinical trial of adjunctive internet-based cognitive behavior therapy for treating major depressive disorder among primary care patients	Trials	23	1	520	BACKGROUND: Major depressive disorder (MDD) is a leading cause of disease morbidity. Combined treatment with antidepressant medication (ADM) plus psychotherapy yields a much higher MDD remission rate than ADM only. But 77% of US MDD patients are nonetheless treated with ADM only despite strong patient preferences for psychotherapy. This mismatch is due at least in part to a combination of cost considerations and limited availability of psychotherapists, although stigma and reluctance of PCPs to refer patients for psychotherapy are also involved. Internet-based cognitive behavioral therapy (i-CBT) addresses all of these problems. METHODS: Enrolled patients (n = 3360) will be those who are beginning ADM-only treatment of MDD in primary care facilities throughout West Virginia, one of the poorest and most rural states in the country. Participating treatment providers and study staff at West Virginia University School of Medicine (WVU) will recruit patients and, after obtaining informed consent, administer a baseline self-report questionnaire (SRQ) and then randomize patients to 1 of 3 treatment arms with equal allocation: ADM only, ADM + self-guided i-CBT, and ADM + guided i-CBT. Follow-up SRQs will be administered 2, 4, 8, 13, 16, 26, 39, and 52 weeks after randomization. The trial has two primary objectives: to evaluate aggregate comparative treatment effects across the 3 arms and to estimate heterogeneity of treatment effects (HTE). The primary outcome will be episode remission based on a modified version of the patient-centered Remission from Depression Questionnaire (RDQ). The sample was powered to detect predictors of HTE that

Zubizarreta, Jose R.							<p>would increase the proportional remission rate by 20% by optimally assigning individuals as opposed to randomly assigning them into three treatment groups of equal size. Aggregate comparative treatment effects will be estimated using intent-to-treat analysis methods. Cumulative inverse probability weights will be used to deal with loss to follow-up. A wide range of self-report predictors of MDD heterogeneity of treatment effects based on previous studies will be included in the baseline SRQ. A state-of-the-art ensemble machine learning method will be used to estimate HTE. DISCUSSION: The study is innovative in using a rich baseline assessment and in having a sample large enough to carry out a well-powered analysis of heterogeneity of treatment effects. We anticipate finding that self-guided and guided i-CBT will both improve outcomes compared to ADM only. We also anticipate finding that the comparative advantages of adding i-CBT to ADM will vary significantly across patients. We hope to develop a stable individualized treatment rule that will allow patients and treatment providers to improve aggregate treatment outcomes by deciding collaboratively when ADM treatment should be augmented with i-CBT. TRIAL REGISTRATION: ClinicalTrials.gov NCT04120285 . Registered on October 19, 2019.</p>
Boswell, James F.; Bugatti, Matteo		An exploratory analysis of the impact of specific interventions: Some clients reveal more than others	Journal of Counseling Psychology	63	6		<p>Recent work has highlighted that process–outcome relationships are likely to vary depending on the client, yet there is little direct evidence regarding specific intervention effects in individual clients. This study attempted to address the hypothesis that some clients reveal more than others regarding the impact of specific interventions. Intensive case study analyses were applied to 2 clients with principal major depressive disorder and</p>

							<p>comorbid anxiety disorders receiving transdiagnostic psychotherapy. Clients completed a battery of symptom and psychological assessments of mindfulness, cognitive reappraisal use, and emotion avoidance on many occasions throughout treatment. Time series analyses were applied to symptom and change construct data. Results included: (a) significant decreases in depression, anxiety, and emotion avoidance from baseline to posttreatment were observed, as well as significant increases in mindfulness and reappraisal; and (b) in one case, intervention strategies exerted little influence on changes in key variables; in the other, emotion exposure strategies had the strongest influence on increases in mindfulness and present-focused awareness strategies had the strongest influence on reductions in emotion avoidance. Even when different clients appear to similarly benefit from the same treatment, specific intervention effects on putative change factors may be more prevalent for some clients and less prevalent for others. Regular assessment is needed to determine if a client requires an alternative set of specific intervention strategies. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Boswell, James F.; Constantino, Michael J.; Kraus, David R.	2017	Harnessing the Therapist Effect in Patient-Centered Mental Health Care Decision Making	Administration and policy in mental health	44	5	724–728	<p>In this commentary, we address the critical importance of the research literature documenting therapist differences in skill and outcomes. In particular, we focus on the implications of therapist differences for patient-centered decision making, including the matching of patients to specific psychotherapists who have empirically-based track records of positive performance. In addition, we present preliminary results from a grant supported study of patients' values and preferences regarding the use of</p>

						provider performance track records in routine mental health care decision making.
Boswell, James F.; Constantino, Michael J.; Oswald, Jennifer M.; Bugatti, Matteo; Goodwin, Brien; Yucel, Recai	2018	Mental health care consumers' relative valuing of clinician performance information	Journal of consulting and clinical psychology	86	4	<p>Background: Research demonstrates significant variability in mental health clinicians' overall and domain-specific effectiveness with their patients. Despite calls to increase patient access to performance information, little is known about patients' relative valuing of this information in the context of other treatment factors.</p> <p>Objective: We aimed to obtain an understanding of patients' relative valuing of provider performance track records and other therapist and treatment characteristics for their mental health care decision making. Method: Participants were 403 (Mage = 41.20; 66.5% female) community mental health patients who completed a multicomponent survey that included an adapted delayed-discounting paradigm to examine the relative valuing. Multiple descriptive, quantitative indices of relative valuing were calculated, as well as an exploratory latent profile analysis to ascertain the presence of homogenous relative-valuing subgroups. Results: Overall, participants valued provider track record information. They also evidenced relatively higher preference values for working with therapists who had specific efficacy in treating their primary problem domain, charged less, and with whom there is a high likelihood of establishing a good alliance. Two latent profiles were identified: one representing higher valuing of provider performance and another consistently representing less emphasis. Participants with higher track-record valuing were younger, believed that therapists are not interchangeable, and endorsed trust in the collection and use of performance information. Conclusion: Harnessing clinician information to make more personalized and</p>

							informed treatment decisions could potentially promote better treatment engagement, retention, and outcomes. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Boterhoven de Haan, Katrina L.; Fassbinder, Eva; Hayes, Chris; Lee, Christopher W.	2019	A schema therapy approach to the treatment of posttraumatic stress disorder	Journal of Psychotherapy Integration	29	1	54–64	<p>Posttraumatic stress disorder (PTSD) is a complex condition often influenced by personality characteristics and comorbidity with other psychiatric disorders. More recent understandings of PTSD have suggested that schemas play a role in the development and maintenance of this condition. Schema therapy (ST) was developed to address more characterological disturbances in chronic disorders. It is an integrative approach for treatment that incorporates practices from other therapeutic orientations. The purpose of this article is to describe some key components of ST and how these can be applied to the treatment of patients with more chronic or complex forms of PTSD. These components include formulating a patients' symptom presentation in terms of their early maladaptive schemas (EMSs) and modes. The assessment of EMS, in particular, takes into account a patients' developmental history and how it has impacted their response to a trauma. In addition, emotion-oriented and experiential techniques are key interventions in ST. Finally, ST has a unique perspective on the therapy relationship, which has been described as "limited reparenting." A case study will be used to demonstrate how these components of ST were effective for intervention where previous techniques had failed. The article concludes with some of the research that supports these components of ST. Specific recommendations are made for future research. Bottari, Sarah A.; Trifilio, Erin R.; Janicke, David M.; Porges, Eric C.; Cohen, Ronald A.; Jaffee, Michael S.; Williamson, John B.	2023	Effects of sleep disturbance on trauma-focused psychotherapy outcomes in posttraumatic stress disorder: A systematic review	Annals of the New York Academy of Sciences	1526	1	30–49	This study aimed to synthesize existing research on the effects of sleep disturbances on trauma-focused psychotherapy outcomes in adults with posttraumatic stress disorder (PTSD). A systematic review using PubMed, PsycINFO, Embase, Web of Science, and PTSDpubs was performed up to April 2021. Two independent reviewers screened articles for inclusion, performed data extraction, and assessed risk of bias and certainty of the evidence. Narrative synthesis was conducted based on the type of sleep disorder symptom assessed. Sixteen primary studies were included in this review, the majority of which had a high overall risk of bias. Results suggested that sleep disorder symptoms were associated with higher overall PTSD severity across treatment; however, they did not interfere with treatment effectiveness, with the exception of sleep-disordered breathing. Improvements in insomnia, sleep duration, and sleep quality during treatment were associated with greater treatment gains. Certainty of the evidence ranged from low to very low. These results suggest that it may not be necessary to address sleep disorder symptoms prior to initiating trauma-focused psychotherapy. Instead, concurrent treatment of sleep- and trauma-related symptoms may be most beneficial. Continued research is needed to clarify the mechanistic relationship between sleep and treatment outcomes and to guide clinical decision-making.
Bottesi, Gioia; Caudek, Corrado; Malerba, Anna; Caselli, Gabriele; Gallo,	2024	Agreement and discrepancies in patient–clinician reports of DSM-5-TR section III	Personality Disorders: Theory, Research, and Treatment		19 49- 27 23(Ele ctr	94–99	The assessment of personality pathology based on dimensional models may improve self–other agreement, but previous research mainly adopted a categorical approach and overlooked the role of the person of the therapist. Our study examined patient–clinician agreement in a mixed sample of Italian outpatients using

<p>Gabriella; Melli, Gabriele; Marsigli, Nicola; Offredi, Alessia; Sica, Claudio</p>		<p>maladaptive personality traits: A study on a mixed outpatient sample</p>			<p>onic), 19 49- 27 15(Print)</p>		<p>the Personality Inventory for DSM-5 (PID-5) and the PID-5-Informant Form (PID-5-IRF). Moreover, the role of clinician personality traits on agreement was preliminary explored. Sixty-eight outpatients (51.4% male, M = 30.30, SD = 12.05 years) and their treating clinicians (N = 22; 77.3% female, M = 43.77 ± 8.45 years) entered the study. Patients completed the PID-5, whereas clinicians filled-in the PID-5-Brief Form (PID-5-BF) and the PID-5-IRF for each patient they involved. A multilevel Bayesian analysis showed that rank-order agreement was large for domains (mean r = .60) and moderate for facets (mean r = .44). As regards mean-level agreement, patient ratings on cognitive/perceptual dysregulation, distractibility, eccentricity, and emotional lability were higher than clinician ratings, whereas patients' scores on depressivity were lower than clinicians' ones. Scores on the PID-5-BF detachment positively predicted agreement on anhedonia, anxiousness, depressivity, distractibility, separation insecurity, and suspiciousness, while scores on the PID-5-BF negative affectivity, antagonism, and disinhibition negatively predicted agreement on few specific facets. Current findings suggest that clinician personality traits may contribute to agreement on maladaptive personality traits, but areas of discrepancies remain in case of low observable internal ones. Since patient-clinician agreement is crucially involved in therapeutic alliance, further research on this issue is highly encouraged. (PsycInfo Database Record (c) 2024 APA, all rights reserved)</p>
<p>Boudreaux, Michael J.; Lengel, Gregory J.; Oltmanns,</p>	<p>2021</p>	<p>Assessment of self-related problems in functioning:</p>	<p>Psychological Assessment</p>	<p>33</p>	<p>6</p>	<p>526-540</p>	<p>This article describes the development and validation of the Intrapersonal Problems Rating Scales (IPRS), a multidimensional measure of self-related problems in personality functioning. Results from a series of factor</p>

Thomas F.; Ozer, Daniel J.		Intrapersonal Problems Rating Scales					<p>analyses performed on self-ratings of over 200 problems revealed seven distinct but interrelated domains of intrapersonal problems: Emotion Dysregulation, Internalizing, Lack of Will, Externalizing, Scrupulousness, Fantasy Proneness, and Apathy. Items were selected and scales built for an efficient assessment of each problem area. The psychometric properties of the resulting scales were then evaluated in an independent sample. Convergent and discriminant validity support for the IPRS was obtained via correlations with respect to three measures of social, emotional, and behavioral problems. The scales associated with a range of personal styles and dispositions and predicted diverse self-reported attitudinal and behavioral criteria even after the effects of normal and maladaptive-range personality traits were removed. Two scoring systems (normative and ipsative, or person-centered, scoring) revealed a differential pattern of associations both internally and with external measures. Interpretive differences between the two scoring procedures are highlighted and potential practical applications of the IPRS are discussed. The instrument can provide additional information not fully accounted for by measures of traits or social functioning and be useful to researchers and practitioners alike to identify, understand, and track changes in a range of intrapersonal problems. Bounoua, Nadia; Abbott, Caroline; Zisk, Abigail; Herres, Joanna;		Emotion regulation and spillover of interpersonal stressors to postsession	Journal of consulting and clinical psychology	86	7		<p>Objective: Little is known about the extent to which previous weeks' stressful events spill over and influence adolescents' abilities to derive insight from treatment sessions. Even less is known about factors that moderate clients' vulnerabilities to these spillover effects. The current study examined the spillover of negative</p>

Diamond, Guy; Kobak, Roger		insight among depressed and suicidal adolescents					interpersonal events to postsession insight and the role of difficulties in emotion regulation in this spillover effect. Method: Participants were 129 adolescents with moderate to severe depressive symptoms and suicidal ideation (Mage = 14.96, 83% female, 56% African American/Black) participating in a comparative efficacy trial of Attachment-Based Family Therapy (ABFT) and Family-Enhanced Nondirective Supportive Therapy (FE-NST). A within-subject mediation model tested pre-session negative affect as a mediator of spillover of past week's events on postsession insight. We then examined baseline difficulties in emotion regulation (DERS) as a between-subjects moderator of the mediation model. Results: Negative affect partially mediated (44%) the spillover of the past week's negative events on adolescents' ratings of postsession insight ($p = .03$, 95% confidence interval, CI [-.09, -.002]). Baseline DERS increased adolescents' vulnerabilities to spillover effects ($p = .01$, 95% CI [-.28, -.03]). Negative interpersonal events from the past week influence pre-session negative affect and spill over to adolescents' abilities to gain insight from their treatment sessions. Adolescents who began treatment with greater DERS were particularly vulnerable to these spillover effects. Findings indicate the need for therapists to adapt sessions to individual differences in depressed and suicidal adolescents' exposure to negative interpersonal events preceding treatment and in their vulnerabilities to spillover and emotion dysregulation. Bouras, A. F.; Ioos, E.; Aoudia, A.; Kaci, H.;	2019	The vision and role of geriatric oncology in	Journal of visceral surgery	156	1	37-44	The phenomenon of population aging is constantly on the rise, as are the medical needs of elderly subjects. Oncological treatment concerns an ever larger number of

Benaibouche, D.; Merad-Boudia, F.		surgical treatment of the elderly patient				<p>elderly patients, raising a number of not only practical and medical questions, but also the ethical interrogations associated with therapeutic decision-making, quality of life and therapeutic obstinacy (futile medical care). Surgeons are increasingly preoccupied by elderly patients on account of the cancer rate among them, and they are compelled to cope with challenges such as morbimortality and prolonged hospitalization. Geriatric oncology is a discipline of increasing importance of which the goal consists in comprehensive care of the elderly cancer patient, care taking into full account his physical and psychological aging, his somatic and cognitive comorbidities, and, last but not least, his life expectancy. The opinions and recommendations of geriatric oncologists provide increasingly more orientation for the oncological therapeutic decision-making processes. The objective of this attempt at clarification is to discuss the contributions of this discipline to everyday surgical activity, to provide surgeons with some tools facilitating initial evaluation of their patients, and to remind the reader of situations in which oncological assistance is of paramount importance.</p>
Bouwuis-Van Keulen, Annette J.; Koelen, Jurriijn; Eurelings-Bontekoe, Liesbeth; Hoekstra-Oomen, Christien; Glas, Gerrit	2023	The evaluation of religious and spirituality-based therapy compared to standard treatment in mental health care: A multi-level meta-analysis of	Psychotherapy research : journal of the Society for Psychotherapy Research		1-14	<p>OBJECTIVE: Psychotherapies are increasingly incorporating spiritual and religious systems of belief and practice, which aligns with recent developments toward person-centered treatments. The main objective of this meta-analysis was to compare the efficacy of a religion and spiritually-based (R/S) therapy to non-R/S treatments. METHOD: A multi-level meta-analysis was conducted to compare randomized controlled studies of the efficacy between R/S-based and regular treatments in mental health care setting. Inclusion criteria were diagnosis, psychotherapeutic treatment, and explicitly</p>

		randomized controlled trials					religion/spirituality therapy. Outcome was assessed for symptoms and for functioning separately, and combined. We also examined several moderators, such as type of comparison, outcome domain, and diagnosis. RESULTS: Overall effect sizes obtained from 23 studies and 27 comparison groups indicated that a R/S treatment is moderately more efficacious compared to regular treatments at posttreatment ($g = .52, p < .01$) and at follow-up ($g = .72, p < .01$) (only available for symptoms). Results were similar for symptoms ($g = .44, p < .01$) and functioning ($g = .62, p < .01$). CONCLUSION: In patients with a strong religious and spiritual affiliation, treatments with a focus on religious and spiritual issues are more efficacious than non-R/S-based therapy. Limitations as well as future directions are discussed.
Braga, Cátia; Ribeiro, António P.; Gonçalves, Miguel M.; Oliveira, João Tiago; Botelho, Alexandra; Ferreira, Helena; Sousa, Inês	2018	Ambivalence resolution in brief psychotherapy for depression	Clinical psychology & psychotherapy	25	3	369–377	Ambivalence in the process of psychotherapeutic change should be addressed and resolved if we are to avoid psychotherapeutic failure and promote sustained change. In this context, ambivalence can be defined as the cyclical conflictual relation between two opposed positions of the self: one expressed as an innovation, and a subsequent one expressed in a trivialization or rejection of the innovation (problematic position). This conflict may be resolved in two different ways: (a) the dominance of the innovative position and the consequent inhibition of the problematic one and (b) the negotiation between the innovative and the problematic positions. In this study, we sought to study the evolution of the dominance and the negotiation processes in recovered and unchanged cases; to analyse if different therapeutic models produce different results on the evolution of the dominance and negotiation processes, and finally, to study if these processes are predictive of ambivalence resolution. The

							complete sessions of 22 clinical cases of depression (6 cognitive-behavioural therapy, 10 narrative therapy, and 6 emotion-focused therapy cases) were independently coded for innovative moments, ambivalence, and ambivalence resolution. Results revealed that recovered cases had a progressively higher proportion of negotiation along treatment, whereas in unchanged cases, negotiation was virtually absent throughout treatment. Both dominance and negotiation were significant predictors of ambivalence reduction, however, negotiation had a higher impact than dominance. Overall, these results did not significantly differ for the 3 therapeutic models. The theoretical implications of these findings are discussed, and theoretical derived suggestions for clinicians are presented.
Braga, Ctia; Oliveira, Joo Tiago; Ribeiro, Antnio P.; Goncalves, Miguel M.	2018	Ambivalence resolution in emotion-focused therapy: The successful case of Sarah	Psychotherapy research: journal of the Society for Psychotherapy Research	28	3	423-432	Ambivalence can be understood as a cyclical movement between two opposing positions of the self: one expressed in a novelty-an innovative moment (IM)-and another one conveyed by a return to the maladaptive pattern. If not properly addressed and resolved during therapy, ambivalence can prevent change and lead to psychotherapeutic failure. Two processes of ambivalence resolution have been suggested: (1) the dominance of the innovative position and consequent inhibition of the problematic position and (2) the negotiation between both positions. To empirically study both processes of ambivalence resolution in a successful case of emotion-focused therapy. Sessions were independently coded with three coding systems-the IMs, the return to the problem and the ambivalence resolution. Ambivalence tended to be resolved from the initial to the final sessions. Although resolutions through dominance tended to decrease and resolutions through negotiation seemingly

							increased along treatment, dominance was, nonetheless, the most prominent process of resolution along the whole treatment. Although it has been suggested that integrating opposing parts of the self is a necessary process for psychotherapeutic success, a less integrative process of ambivalence resolution may also be an important resource along the process.
Bragesjö, Maria; Arnberg, Filip K.; Andersson, Erik	2021	Prevention of post-traumatic stress disorder: Lessons learned from a terminated RCT of prolonged exposure	PloS one	16	5	e0251898	The main purpose of the current trial was to test if a brief trauma-focused cognitive-behaviour therapy protocol (prolonged exposure; PE) provided within 72 h after a traumatic event could be effective in decreasing the incidence of post-traumatic stress disorder (PTSD), thus replicating and extending the findings from an earlier trial. After a pilot study (N = 10), which indicated feasible and deliverable study procedures and interventions, we launched an RCT with a target sample size of 352 participants randomised to either three sessions of PE or non-directive support. Due to an unforeseen major reorganisation at the hospital, the RCT was discontinued after 32 included participants. In this paper, we highlight obstacles and lessons learned from our feasibility work that are relevant for preventive psychological interventions for PTSD in emergency settings. One important finding was the high degree of attrition, and only 75% and 34%, respectively, came back for the 2-month and 6-month assessments. There were also difficulties in reaching eligible patients immediately after the event. Based on our experiences, we envisage that alternative models of implementation might overcome these obstacles, for example, with remote delivery of both assessments and interventions via the internet or smartphones combined with multiple recruitment

							procedures. Lessons learned from this terminated RCT are discussed in depth.
Brakemeier, Eva-Lotta; Hauck, Sophie; Harder, Florian	2023	Interpersonelle Psychotherapie (IPT). Ein evidenzbasiertes und praxisorientiertes Update zur Wirksamkeit, Durchführung und zu Weiterentwicklungen	PSYCH up2date	17	4	337–357	Depressionen und andere psychische Strungen werden häufig durch interpersonelle Probleme (wie Konflikte, Rollenwechsel, komplizierte Trauer oder Isolation) ausgelöst oder aufrechterhalten. Die interpersonelle Psychotherapie (IPT) hat sich in vielen Studien als eine wirksame Psychotherapie für Menschen mit derartigen interpersonellen Problemen erwiesen. Dieser Beitrag gibt ein evidenzbasiertes und praxisorientiertes Update zur Wirksamkeit, Durchführung und zu Weiterentwicklungen der IPT. (c) Thieme. All rights reserved.
Brakemeier, Eva-Lotta; Jacobi, Frank	2017	Verhaltenstherapie in der Praxis					In einem Lehrbuch wird Psychotherapeuten in Ausbildung, zu Beginn der Berufstätigkeit, aber auch nach langjähriger Berufserfahrung das Handwerkszeug moderner Verhaltenstherapie und ihrer aktuellen Weiterentwicklungen vermittelt. Brandmeyer, Tracy; Delorme, Arnaud	2018	Reduced mind wandering in experienced meditators and associated EEG correlates	Experimental brain research	236	9	2519–2528	One outstanding question in the contemplative science literature relates to the direct impact of meditation experience on the monitoring of internal states and its respective correspondence with neural activity. In particular, to what extent does meditation influence the awareness, duration and frequency of the tendency of the

						<p>mind to wander. To assess the relation between mind wandering and meditation, we tested 2 groups of meditators, one with a moderate level of experience (non-expert) and those who are well advanced in their practice (expert). We designed a novel paradigm using self-reports of internal mental states based on an experiential sampling probe paradigm presented during ~1 h of seated concentration meditation to gain insight into the dynamic measures of electroencephalography (EEG) during absorption in meditation as compared to reported mind wandering episodes. Our results show that expert meditation practitioners report a greater depth and frequency of sustained meditation, whereas non-expert practitioners report a greater depth and frequency of mind wandering episodes. This is one of the first direct behavioral indices of meditation expertise and its associated impact on the reduced frequency of mind wandering, with corresponding EEG activations showing increased frontal midline theta and somatosensory alpha rhythms during meditation as compared to mind wandering in expert practitioners. Frontal midline theta and somatosensory alpha rhythms are often observed during executive functioning, cognitive control and the active monitoring of sensory information. Our study thus provides additional new evidence to support the hypothesis that the maintenance of both internal and external orientations of attention may be maintained by similar neural mechanisms and that these mechanisms may be modulated by meditation training.</p>
Braun, Alexandra; Evdokimov, Dimitar; Frank,	2020	Clustering fibromyalgia patients: A combination of	PLoS ONE, 2020			<p>Background: Coping strategies and their efficacy vary greatly in patients suffering from fibromyalgia syndrome (FMS). Objective: We aimed to identify somatic and psychosocial factors that might contribute to different</p>

Johanna; Pauli, Paul; ceyler, Nurcan; Sommer, Claudia		psychosocial and somatic factors leads to resilient coping in a subgroup of fibromyalgia patients				<p> coping strategies and resilience levels in FMS. Subjects and methods: Standardized questionnaires were used to assess coping, pain, and psychological variables in a cohort of 156 FMS patients. Quantitative real-time polymerase chain reaction (qRT-PCR) determined gene expression of selected cytokines in white blood cells of 136 FMS patients and 25 healthy controls. Data of skin innervation, functional and structural sensory profiles of peripheral nociceptive nerve fibers of a previous study were included into the statistics. An exploratory factor analysis was used to define variance explaining factors, which were then included into cluster analysis. Results: 54.9% of the variance was explained by four factors which we termed (1) affective load, (2) coping, (3) pain, and (4) pro-inflammatory cytokines ($p < 0.05$). Considering differences in the emerged factors, coping strategies, cytokine profiles, and disability levels, 118 FMS patients could be categorized into four clusters which we named "maladaptive", "adaptive", "vulnerable", and "resilient" ($p < 0.05$). The adaptive cluster had low scores in disability and in all symptom categories in contrast to the vulnerable cluster, which was characterized by high scores in catastrophizing and disability ($p < 0.05$). The resilient vs. the maladaptive cluster was characterized by better coping and a less pro-inflammatory cytokine pattern ($p < 0.05$). Conclusion: Our data suggest that problem- and emotion-focused coping strategies and an anti-inflammatory cytokine pattern are associated with reduced disability and might promote resilience. Additional personal factors such as low anxiety scores, ability of acceptance, and persistence further favor a resilient phenotype. Individualized therapy should take these factors into account.</p>

Braun, Esther; Gaillard, Anne-Sophie; Vollmann, Jochen; Gather, Jakov; Scholten, Matthé	2023	Mental Health Service Users' Perspectives on Psychiatric Advance Directives: A Systematic Review	Psychiatric services (Washington, D.C.)	74	4	381–392	<p>OBJECTIVE: Psychiatric advance directives (PADs) are documents that allow users of mental health services to express their preferences for treatment in future mental health crises. To increase the use of PADs in psychiatric practice, it is helpful to consider how service users view PADs and the factors that facilitate or hinder PAD creation and implementation. A systematic review of the empirical literature on this topic may help inform evidence-based policy making. METHODS: A systematic review concordant with PRISMA guidelines was conducted. Relevant electronic databases were searched up to July 2, 2021. Articles containing original empirical data on service users' perspectives on PADs were included. Data were analyzed thematically, tabulated, and narratively synthesized. RESULTS: Fifty-three articles were identified and included. The following categories were identified: general preferences regarding factors such as legal force and revocability; benefits of PADs at the personal, treatment-related, and social levels; challenges and barriers concerning PAD creation and application; and possible and experienced facilitators of PAD creation. CONCLUSIONS: Users of mental health services are highly interested in PADs and regard them as tools to improve their involvement in care. They generally prefer legally binding PADs that can be revoked only when users are competent to consent. Barriers reported by service users were mainly related to the creation and application of PADs, and support in PAD creation was the most important facilitator identified. The involvement of mental health professionals in creating PADs appears essential to realize the benefits of PADs and to reduce barriers to their use.</p>

<p>Brave Heart, Maria Yellow Horse; Chase, Josephine; Myers, Orrin; Elkins, Jennifer; Skipper, Betty; Schmitt, Cheryl; Mootz, Jennifer; Waldorf, V. Ann</p>		<p>Iwankapiya American Indian pilot clinical trial: Historical trauma and group interpersonal psychotherapy</p>	<p>Psychotherapy</p>	<p>57</p>	<p>2</p>	<p>American Indians face pervasive trauma exposure, collective histories of communal suffering, and elevated risk for depression and posttraumatic stress disorder. In addition to socioeconomic barriers, access to culturally responsive treatment is limited, which may compromise treatment engagement. The Iwankapiya study piloted the Historical Trauma and Unresolved Grief Intervention (HTUG), combined with Group Interpersonal Psychotherapy (IPT), to reduce symptoms of depression and related trauma and grief. The study hypothesized that HTUG + IPT would lead to greater group engagement and decreased depression and related symptoms compared with IPT-Only. American Indian adults (n = 52) were randomized into one of two 12-session interventions, HTUG + IPT or IPT-Only, at two tribal sites: one Northern Plains reservation (n = 26) and one Southwest urban clinic (n = 26). Standardized measures assessed depression, posttraumatic stress disorder, grief, trauma, and substance use. Data were collected at screening, baseline, end of intervention, and 8 weeks postintervention; depression and group engagement measures were also collected at Weeks 4 and 8 of the intervention. Depression scores significantly decreased for both treatments, but there were no significant differences in depression between the two groups: IPT-Only (30.2 ± 6.4 at baseline to 16.7 ± 12.1 at follow-up) and HTUG + IPT (30.2 ± 8.1 at baseline to 19.9 ± 8.8 at follow-up). However, HTUG + IPT participants demonstrated significantly greater group engagement. Postintervention, clinicians expressed preference for HTUG + IPT based upon qualitative observations of greater perceived gains among participants. Given the degree of trauma exposure in tribal communities, these</p>

Brckl, Marieluise	2020	Personzentriertes diagnostisches Verstehen und der ganzheitliche Blick auf das Individuum	Psychotherapie Forum	24	1-2	55-62	Diagnostik im personzentrierten Verständnis ist ein Teil der Therapie bzw. eine den Prozess begleitende Diagnostik und wird an Hand der Arbeit mit einer fünfzehnjährigen Jugendlichen beschrieben. Nach einer kurzen Darstellung der Therapieeingangsdagnostik werden die Entwicklung beziehungsweise die Stagnation des Selbstkonzeptes und daraus entstehende Inkongruenzkonstellationen sowie die Beziehungsfähigkeit der Klientin bzw. ihre Beziehungsgestaltung im Kontakt zur Therapeutin hinsichtlich ihrer Relevanz für den diagnostischen Prozess und für den Verlauf der Psychotherapie genauer beschrieben. Außerdem wird während des Prozesses darauf Wert gelegt, die Erfahrungen der Jugendlichen konsequent aus ihrem inneren Bezugsrahmen heraus zu verstehen.
Breil, Janine; Sachse, Rainer	2018	Klärungsorientierte Psychotherapie der Borderline-Persönlichkeitsstörung					Möglichkeiten der klärungsorientierten Psychotherapie der Borderline-Persönlichkeitsstörung (BPS) werden beschrieben. Während für die Emotionsregulationsstörung der Borderline-Persönlichkeitsstörung mit der dialektisch-behavioralen Therapie ein wirksames Behandlungskonzept vorliegt, mangelt es in der klinischen Praxis an Unterstützung beim Umgang mit dem typischen dysfunktionalen Interaktionsverhalten bei dieser Störung. Die klärungsorientierte Psychotherapie wird als eine Lösung für dieses Problem präsentiert. Zunächst verschiedene Dimensionen zur Konzeptualisierung der BPS vorgeschlagen und mit dazu passenden Störungsmodellen beschrieben. Anschließend wird auf die konkrete praktische Umsetzung im Therapieprozess

							<p>eingegangen: berlegungen zur Therapieplanung bei gleichzeitigem Vorliegen verschiedener Problembereiche werden angestellt, und es wird dargelegt, wie Methoden der Beziehungsgestaltung integriert werden knnen. Auch die Konfrontation mit der Spielebene und die Klrung und Bearbeitung von Schemata anhand eines mit unterschiedlichen Persnlichkeitsanteilen arbeitenden Rahmenmodells wird besprochen. Das konkrete Vorgehen wird durch Beispiele und Transkripte veranschaulich. - Inhalt: (1) Charakteristika und Merkmale der Borderline-Persnlichkeitsstrung. (2) Weitergehende Beschreibung der Borderline-Persnlichkeitsstrung. (3) Problemfeld: Emotionsregulationsstrung. (4) Problemfeld: Schwierigkeiten in Beziehungen. (5) Das Verhlttnis der Problemfelder zueinander. (6) Strungsmodell fr das Problemfeld Schwierigkeiten in Beziehungen. (7) Therapie. (8) Beziehungsaufbau. (9) Diagnostik und Therapieplanung. (10) Konfrontation mit der Spielebene. (11) Schemaklrung und -bearbeitung. (12) Das kombinierte therapeutische Vorgehen. (13) Umgang mit manipulativen Aspekten von Selbstverletzungen. (14) Umgang mit manipulativer Suizidalitt. (15) Erneute Traumatisierung. (16) Transkripte zur Illustration von Therapie.</p>
Breitbart, William; Pessin, Hayley; Rosenfeld, Barry; Applebaum, Allison J.; Lichtenthal,	2018	Individual meaning-centered psychotherapy for the treatment of psychological and existential	Cancer	124	15	3231–3239	<p>BACKGROUND: Patients with advanced cancer have high rates of psychological distress, including depression, anxiety, and spiritual despair. This study examined the effectiveness of individual meaning-centered psychotherapy (IMCP) in comparison with supportive psychotherapy (SP) and enhanced usual care (EUC) in improving spiritual well-being and quality of life and reducing psychological distress in patients with advanced</p>

Wendy G.; Li, Yuelin; Saracino, Rebecca M.; Marziliano, Allison M.; Masterson, Melissa; Tobias, Kristen; Fenn, Natalie		distress: A randomized controlled trial in patients with advanced cancer					cancer. METHODS: Patients (n = 321) were randomly assigned to IMCP (n = 109), SP (n = 108), or EUC (n = 104). Assessments were conducted at 4 time points: before intervention, midtreatment (4 weeks), 8 weeks after treatment, and 16 weeks after treatment. RESULTS: Significant treatment effects (small to medium in magnitude) were observed for IMCP, in comparison with EUC, for 5 of 7 outcome variables (quality of life, sense of meaning, spiritual well-being, anxiety, and desire for hastened death), with Cohen's d ranging from 0.1 to 0.34; no significant improvement was observed for patients receiving SP (d < 0.15 and P > .05 for all variables). The effect of IMCP was significantly greater than the effect of SP for quality of life and sense of meaning (d = 0.19) but not for the remaining study variables. CONCLUSIONS: This study provides further support for the efficacy of IMCP as a treatment for psychological and existential/spiritual distress in patients with advanced cancer. Significant treatment effects (small to moderate effect sizes) were observed in comparison with usual care, and somewhat more modest differences in improvement (small effect sizes) were observed in comparison with SP. Thus, the benefits of meaning-centered psychotherapy appear to be unique to the intervention and highlight the importance of addressing existential issues with patients approaching the end of life. Breitenstein, Susan M.; Laurent, Stacy; Pabalan, Laura; Risser, Heather J.; Roper,	2019	Implementation findings from an effectiveness-implementation trial of tablet-based parent	Families, Systems, & Health	37	4	282-290	Introduction: The use of mobile delivery to deliver parent training can address barriers to access and improve the translation of interventions in existing settings like pediatric primary care. Studying implementation provides critical information to identify and address barriers and facilitators and inform sustainability efforts. Method: This

Pamela; Saba, Mary T.; Schoeny, Michael		training in pediatric primary care					<p>study was a descriptive evaluation using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework as part of a Hybrid Type I Effectiveness-Implementation trial of the ezParent Program within 4 pediatric primary care clinics. We collected data before, during, and after implementation to evaluate provider implementation and their perspectives on program benefits and barriers to implementation. Results: On average, 14% of eligible parents were introduced to the study. Of these parents, 78% expressed interest in participating and 37% enrolled in the study. Seventy-eight percent of staff providers (n = 36) implemented the procedures at least once, and among those who implemented 3 or more times (n = 24), 79% maintained implementation for 6 months. Barriers to implementation include limited time, lack of information, and full practice buy-in and engagement. Discussion: Implementation fidelity may improve with additional education and training of the interdisciplinary team, clear messaging regarding the purpose and content of the ezParent program, defining roles within the care team, identifying practice champions, and use of the electronic health record. Findings from this evaluation, including data from the randomized controlled trial and literature to support intervention effectiveness and implementation, will be used to develop an implementation toolkit to include specific strategies for implementation and ideas for local adaptations. Brem, Meagan J.; Shorey, Ryan C.; Anderson,	2017	Depression, anxiety, and compulsive sexual	Clinical psychology & psychotherapy	24	6	1246–1253	<p>Nearly one-third of individuals in treatment for substance use disorders endorse at-risk levels of compulsive sexual behaviours (CSBs). Untreated sexual compulsivity may facilitate relapse for treatment-seeking men. Previous</p>

<p>Scott; Stuart, Gregory L.</p>		<p>behaviour among men in residential treatment for substance use disorders: The role of experiential avoidance</p>				<p>research and theory suggest that CSBs are maintained by efforts to escape or alter negative affect (e.g., depression and anxiety). However, this hypothesis has not been examined within a sample of men in treatment for substance use disorders. In an effort to better understand CSBs within a population of men with substance use disorders, the present study is the first to examine experiential avoidance as one potential mechanism underlying the relation between men's symptoms of depression and anxiety and their use of CSBs. The present study reviewed medical records of 150 men in residential treatment for substance use disorders. Structural equation modelling was used to examine pathways from men's depression and anxiety symptoms to CSBs directly and indirectly through experiential avoidance while controlling for alcohol/drug problems and use. Results revealed significant indirect effects of both depression and anxiety symptoms on CSB through experiential avoidance. These results support and extend existing research on CSB in a treatment population. Findings suggest that intervention efforts for CSB may benefit by targeting men's avoidance of painful internal events. KEY PRACTITIONER MESSAGE: Compulsive sexual behaviour is related to symptoms of depression and anxiety amongst men in residential treatment for substance use disorders. Experiential avoidance is positively related to compulsive sexual behaviour amongst men with substance use disorders. For men in treatment for substance use disorders, the relation between symptoms of depression and anxiety and compulsive sexual behaviour is explained, in part, by experiential avoidance. Helping men with substance use disorders develop more adaptive methods of processing</p>

							aversive experiences, as opposed to escaping them, may reduce their use of compulsive sexual behaviours when faced with aversive affect.
Brenes, Gretchen A.; Danhauer, Suzanne C.; Lyles, Mary F.; Anderson, Andrea; Miller, Michael E.	2016	Effects of Telephone-Delivered Cognitive-Behavioral Therapy and Nondirective Supportive Therapy on Sleep, Health-Related Quality of Life, and Disability	The American journal of geriatric psychiatry : official journal of the American Association for Geriatric Psychiatry	24	10	846-854	<p>OBJECTIVES: The purpose of this study was to compare the effects of cognitive-behavioral therapy delivered by telephone (CBT-T) and telephone-delivered nondirective supportive therapy (NST-T) on sleep, health-related quality of life, and physical disability in rural older adults with generalized anxiety disorder. METHODS: This was a secondary analysis of a randomized clinical trial on 141 rural-dwelling adults 60 years and older diagnosed with generalized anxiety disorder. Sleep was assessed with the Insomnia Severity Index. Health-related quality of life was assessed with the 36-item Short-Form Health Survey (SF-36). Physical disability was assessed with the Pepper Center Tool for Disability. Assessments occurred at baseline, 4 months, 9 months, and 15 months. RESULTS: Insomnia declined in both groups from baseline to 4 months, with a significantly greater improvement among participants who received CBT-T. Similarly, Mental and Physical Component Summaries of the SF-36 declined in both groups, with a differential effect favoring CBT-T. Participants in both interventions reported declines in physical disability, although there were no significant differences between the two interventions. Improvements in insomnia were maintained at the 15-month assessment, whereas between-group differences shrank on the Mental and Physical Component Summaries of the SF-36 by the 15-month assessment. CONCLUSION: CBT-T was superior to NST-T in reducing insomnia and improving health-related quality of life. The effects of CBT-T on sleep were maintained 1 year after completing the treatment.</p>

<p>Brenes, Gretchen A.; Danhauer, Suzanne C.; Lyles, Mary F.; Anderson, Andrea; Miller, Michael E.</p>	<p>2017</p>	<p>Long-Term Effects of Telephone-Delivered Psychotherapy for Late-Life GAD</p>	<p>The American journal of geriatric psychiatry : official journal of the American Association for Geriatric Psychiatry</p>	<p>25</p>	<p>11</p>	<p>1249-1257</p>	<p>OBJECTIVE: To examine the long-term effects of telephone-delivered cognitive-behavioral therapy (CBT-T) compared with nondirective supportive therapy (NST-T) in rural older adults with generalized anxiety disorder (GAD). METHODS: 141 adults aged 60 years and older with a principal/co-principal diagnosis of GAD were randomized to either CBT-T or NST-T. CBT-T consisted of up to 11 sessions (9 were required) focused on recognition of anxiety symptoms, relaxation, cognitive restructuring and use of coping statements, problem-solving, worry control, behavioral activation, exposure therapy, and relapse prevention, with optional chapters on sleep and pain. NST-T consisted of 10 sessions focused on providing a supportive atmosphere in which participants could share and discuss their feelings and did not provide any direct suggestions. Primary outcomes included interviewer-rated anxiety severity and self-report worry severity measured at 9 months and 15 months after randomization. Mood-specific secondary outcomes included self-report GAD symptoms and depressive symptoms. RESULTS: At 15 months, after adjustment for multiple testing, there was a significantly greater decline in general anxiety symptoms (difference in improvement: 3.31; 95% CI: 0.45-6.17; t = 2.29; df = 136; p = 0.024) and worry (difference in improvement: 3.13; 95% CI: 0.59-5.68; t = 2.43; df = 136; p = 0.016) among participants in CBT-T compared with those in the NST-T group. There were no significant differences between the conditions in terms of depressive symptoms (difference in improvement: 2.88; 95% CI: 0.17-5.60; t = 2.10; df = 136; p = 0.0376) and GAD symptoms (difference in improvement: 1.65; 95% CI: -0.20 to 3.50; t = 1.76; df = 136; p = 0.080). CONCLUSIONS: CBT-T is superior to NST-</p>

Brenig-Eggebrecht, Margit	2017	Transponibles, integratives, prozessuales Psychotherapie modell TIPP. Das Praxishandbuch					<p>Im Rahmen eines Praxishandbuchs wird das Transponible Integrative Prozessuale Therapiemodell (TIPP) für Psychotherapie und Beratung vorgestellt. TIPP ist ein neuartiges leichtes Modell zur Integration vieler Variablen des therapeutischen Prozesses und Elemente unterschiedlicher Therapieansätze. Kern des Modells ist eine Abbildung, die anhand farbiger Symbole Vergangenes, Gegenwärtiges und Zukünftiges im Leben der Klienten erfasst und damit auf einen Blick darstellt. Ebenso können die Symbole für Elemente verschiedener Therapieansätze stehen, mit denen im weiteren Verlauf gearbeitet werden kann. Therapeuten und Klienten erstellen die Abbildung schrittweise gemeinsam und machen so das Erleben der Klienten und daraus hervorgehende Therapieziele sowie deren Bearbeitungsmöglichkeiten anschaulich und greifbar. Darüber hinaus bietet TIPP Hilfestellungen für Berichte an den Gutachter. Bei einem Download-Code erhält man Zugang zur PDF-Version des Buchs. - Inhalt: (1) Einführung in die Arbeit mit TIPP (Struktur des Bildes; Symbolik). (2) Einordnung von TIPP (Bild und Grafik; Projektionsfläche; Psychotherapiemodell; psychotherapeutische Methode; humanistische Tradition; wissenschaftstheoretische Überlegungen; Neuartigkeit). (3) Sprache und Metaphern (Semiotik und Sprachphilosophie; Metaphorik; Metaphern in der Psychotherapie). (4) Integrativität. (5) Transponibilität verschiedener Behandlungsansätze auf TIPP (Verhaltenstherapie (multimodale Therapie: BASIC-ID; Konsistenztheorie und Plananalyse; kognitive Verhaltenstherapie der Depression; CBASP in der Behandlung chronisch depressiver Patienten;</p>

							Schematherapie; Dialektisch-Behaviorale Therapie; Akzeptanz- und Commitmenttherapie); psychodynamische Therapie; klientenzentrierte Psychotherapie; Gestalttherapie; emotionsfokussierte Psychotherapie). (6) Einsatzmöglichkeiten (Einzels psychotherapie; Familien- und Paartherapie; Psychotherapiegruppe; Kinder- und Jugendlichenpsychotherapie; Supervision; einstieg in TIPP). Brenner, Rachel E.; Cornish, Marilyn A.; Heath, Patrick J.; Lannin, Daniel G.; Losby, Madelyn M.	2020	Seeking help despite the stigma: Experiential avoidance as a moderated mediator	Journal of Counseling Psychology	67	1	132-140	The help-seeking literature identifies a model wherein public stigma of seeking help is internalized as self-stigma of seeking help, which, in turn, decreases help-seeking outcomes. The current study considered whether experiential avoidance, or a tendency to avoid painful thoughts or emotions, moderates how strongly these stigmata relate to help-seeking intentions among university students. Specifically, this study tested whether experiential avoidance moderates (a) the direct relationship between self-stigma of seeking psychological help and help-seeking intentions and (b) the indirect relationship between public stigma and help-seeking intentions. Conditional process modeling in a university student sample (N = 235) supported these hypotheses. The direct relationship between self-stigma and help-seeking intentions was nonsignificant and weaker for those who reported low experiential avoidance than for those who reported high experiential avoidance. Results also demonstrated a moderated indirect effect wherein the relationship between self-stigma and intentions was nonsignificant among those reporting low levels of

						<p>experiential avoidance. This suggests that self-stigma may predict help-seeking intentions when avoidance of therapy functions as a means for avoiding unpleasant emotions. These findings suggest that interventions designed to decrease experiential avoidance by increasing openness to unpleasant emotions may offer a novel avenue to attenuate the impact of self-stigma on help-seeking intentions without requiring the difficult task of reducing stigma altogether. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Breywisch, Ute; Zepperitz, Sabine	2022	Ein entwicklungsba siertes Wohngruppenko nzept fr Menschen mit schwerer und schwerster intellektueller Beeintrchtigung				<p>Ein auf dem SEED-Modell (Skala der Emotionalen Entwicklung - Diagnostik; SEED) grndendes entwicklungsangemessenes Wohngruppenkonzept fr Menschen mit schwerer und schwerster intellektueller Beeintrchtigung wird beschrieben. Nach einer Begrndung des SEED-basierten Wohnkonzepts wird im Einzelnen auf folgende Aspekte eingegangen: Rahmenbedingungen (Team, Arbeitsorganisation, Ort), Umsetzung der SEED-basierten Begleitung (Gestaltung von Nhe zu Bezugspersonen, Gestaltung von Sicherheit und Vorhersehbarkeit bei fehlender Objektpermanenz, Umgang mit Emotionen und Affektregulation, Gestaltung von Kommunikation, Umgang mit Material/Aktivitten), personenzentrierte Teilhabe (Gesundheitsfrsorge, Evaluation). Erfahrungen mit diesem Ansatz werden an einem Fallbeispiel sowie in Bezug auf die Kostentrger berichtet. In tabellarischer Form werden abschlieend Empfehlungen zur Umsetzung eines entwicklungsgerechten Wohnkonzepts fr Menschen mit schwerer und schwerster intellektueller Entwicklungsstrung wiedergegeben.</p>

Bringmann, Holger C.; Bringmann, Nicole; Jeitler, Michael; Brunnhuber, Stefan; Michalsen, Andreas; Sedlmeier, Peter	2021	Meditation Based Lifestyle Modification (MBLM) in outpatients with mild to moderate depression: A mixed-methods feasibility study	Complementary therapies in medicine	56		102598	<p>BACKGROUND: Integrative mental health care can be applied to treat depression with a person-centered, lifestyle-modifying, and more salutogenic approach to mental health and human flourishing. In this article, we report on the feasibility and acceptability of a new mind-body program, Meditation Based Lifestyle Modification (MBLM), in outpatients with mild or moderate depression.</p> <p>METHODS: This is a single-arm mixed-methods feasibility study of n = 25 outpatients in psychiatric care. Depressive symptoms, scores for mindfulness, aspects of spirituality, and eudaemonic well-being based on yoga philosophy were assessed at baseline and at the end of the intervention. Adherence was monitored and face-to-face interviews were held after the program to explore the acceptability and feasibility of MBLM.</p> <p>RESULTS: Twenty patients (75 %) completed at least six sessions of the course. Adherence was 87.5 % of allocated sessions. In qualitative analysis, more than half of the participants experienced novelty and inspiration through practicing the ethical aspects of yoga (e.g., nonviolence, truthfulness, etc.). Almost all participants experienced a decrease in emotional distress. Virtually all participants reported more self-confidence and self-acceptance. In quantitative analysis, participants reported a clinically important decrease in depressive symptoms of 39.23 % (p = .002), eudaemonic well-being increased significantly in a range of related scales and scores for mindfulness increased (p < .001).</p> <p>CONCLUSION: MBLM is a highly acceptable and feasible program for outpatients with mild to moderate depression. This comprehensive, lifestyle-modifying approach is highly relevant to preventing and treating mental illness, and treating</p>

							psychic comorbidities in patients with chronic somatic illness.
Brintzinger, Miriam; Tschacher, Wolfgang; Endtner, Katrin; Bachmann, Kurt; Reicherts, Michael; Znoj, Hansjörg; Pfammatter, Mario		Patients' style of emotional processing moderates the impact of common factors in psychotherapy	Psychotherapy	58	4		This study examined how patient characteristics concerning processing of emotions interact with common factors in psychotherapy. We focused on common factors of emotional processing in psychotherapy with regard to depression outcome. A total of 93 psychiatric outpatients were included. Patients completed preassessments and postassessments regarding depression symptoms and emotional processing style. In addition, the subjectively perceived activation of common factors related to emotional processing in therapy was assessed by the patients after each therapy session. Depending on patients' pretreatment characteristics in emotional processing, activation of the emotion-related common factor mindfulness in treatment had varying impact on depression outcome: The perceived activation of mindfulness had a positive impact on depression reduction only in patients with pretreatment deficits in cognitive representation and communication of emotions. In patients who did not show such deficits, the perceived activation of this common factor during treatment was negatively correlated with outcome. It appears that common factors in psychotherapy must match with patient characteristics to gain therapeutic significance. Examining the interplay of patient characteristics with common factors provides a promising approach to tailor psychotherapeutic procedures in the sense of a personalized psychotherapy. Brody, Janet L.; Scherer, David	2018	A Conceptual Model and	Family process	57	2	510–524	Individual and group-based psychotherapeutic interventions increasingly incorporate mindfulness-based

<p>G.; Turner, Charles W.; Annett, Robert D.; Dalen, Jeanne</p>		<p>Clinical Framework for Integrating Mindfulness into Family Therapy with Adolescents</p>				<p>principles and practices. These practices include a versatile set of skills such as labeling and attending to present-moment experiences, acting with awareness, and avoiding automatic reactivity. A primary motivation for integrating mindfulness into these therapies is compelling evidence that it enhances emotion regulation. Research also demonstrates that family relationships have a profound influence on emotion regulation capacities, which are central to family functioning and prosocial behavior more broadly. Despite this evidence, no framework exists to describe how mindfulness might integrate into family therapy. This paper describes the benefits of mindfulness-based interventions, highlighting how and why informal mindfulness practices might enhance emotion regulation when integrated with family therapy. We provide a clinical framework for integrating mindfulness into family therapy, particularly as it applies to families with adolescents. A brief case example details sample methods showing how incorporating mindfulness practices into family therapy may enhance treatment outcomes. A range of assessment modalities from biological to behavioral demonstrates the breadth with which the benefits of a family-based mindfulness intervention might be evaluated.</p> <p>Las intervenciones psicoterapéuticas individuales y grupales incorporan cada vez más principios y prácticas basados en la conciencia plena. Estas prácticas incluyen un conjunto polivalente de habilidades, por ejemplo, etiquetar y estar atento a experiencias del momento actual, actuar con conciencia y evitar la reacción automática. Una motivación fundamental para integrar la conciencia plena en estas terapias es la prueba convincente de que mejora la regulación de emociones.</p>
---	--	--	--	--	--	---

						<p>Las investigaciones también demuestran que las relaciones familiares tienen una profunda influencia en las habilidades de regulación de las emociones, que son fundamentales para el funcionamiento familiar y el comportamiento prosocial en líneas generales. A pesar de esta prueba, no existe un marco que describa cómo la conciencia plena podría integrarse en la terapia familiar. Este artículo describe los beneficios de las intervenciones basadas en la conciencia plena y destaca cómo y por qué las prácticas de conciencia plena informal podrían mejorar la regulación de emociones cuando se las integra con la terapia familiar. Ofrecemos un marco clínico para integrar la conciencia plena en la terapia familiar, particularmente para aplicarla a familias con adolescentes. Un breve caso práctico detalla métodos que muestran cómo la incorporación de las prácticas de conciencia plena en la terapia familiar puede mejorar los resultados de los tratamientos. Diversas modalidades de evaluación, desde biológicas hasta conductuales, demuestran la amplitud con la cual podrían evaluarse los beneficios de una intervención familiar con conciencia plena.</p> <p>以正念为基础的原则和实践日益被纳入个人和群体为基础的心理治疗干预措施。这些做法包括一系列多样化技能,例如标识和着意当前经历,有意识的行动,以及避免自动反应性。将正念纳入心理治疗的一个主要动机是有力的证据表明正念可以增强情绪管理。研究还表明家庭关系对于情绪管理能力有重要影响,而情绪管理能力对于更广泛的家庭功能和健康社会行为至关重要。尽管有这些证据,目前还没有框架来描述如何将正念纳入家庭心理治</p>

						<p>疗。本文描述了正念为基础干预措施的益处,并强调将非正式正念做法纳入家庭心理治疗如何以及为什么可能提升情绪管理。我们为将正念纳入家庭心理治疗提供了临床框架,特别是将其应用与有青少年的家庭中。一个简短的案例详细阐明样本方法,表明将正念做法纳入家庭心理治疗如何能够提升治疗效果。一系列评估模型(从生物学到行为学)表明以家庭为基础正念干预措施疗效可以被评估的广度。</p>
<p>Brokuslaus, Ilona; Welke, Thorsten; Edel, Arno</p>	<p>2021</p>	<p>Bewegen statt Erstarren!. Das Praxisbuch fr DBT-Krperskills</p>				<p>Die Dialektisch Behaviorale Therapie (DBT) ist eine emotionsfokussierte und erfahrungsorientierte Verhaltenstherapie. Emotionen drcken sich wesentlich im Krper aus und sind ber diesen erfahr- und auch vernderbar. Aus diesem Grund ist es in der DBT besonders sinnvoll, den "Erfahrungsraum Krper" in die Behandlung von Borderline-Patientinnen und -Patienten zu integrieren. Vor diesem Hintergrund werden die DBT-Krperskills vorgestellt, die in der Einzel- oder Gruppentherapie vermittelt werden knnen. Das Themenspektrum reicht von Warm-Up-bungen ber Atembungen, den Umgang mit Nhe und Distanz, den Einbezug der Krpersprache bis hin zu Selbstwert und Grundbungen des Jonglierens. In der Einbettung in die umfassende DBT-Behandlung knnen so die Leitsymptome der Borderline-Strung wie Anspannungs- und Dissoziationsphnomene mittels Bewegung und krperlicher Aktivitt funktional bewtigt werden. Das Buch richtet sich an: Psychotherapeutinnen und Psychotherapeuten, Psychiaterinnen und Psychiater, Pflegekrfte, Sozialarbeiterinnen und Sozialarbeiter, Mitarbeiterinnen und Mitarbeiter von DBT-Stationen und</p>

							allgemeinpsychiatrischen Stationen sowie Borderline-Patientinnen und -Patienten. - Inhalt: (1) Grundlagen. (2) Struktur, Ziele und Modalitäten der DBT-Körpertherapie. (3) Der Erstkontakt. (4) Basisübungen. (5) Die Bewegungsanalyse. (6) Warm-up-übungen. (7) Körperbezogene Achtsamkeitsübungen. (8) Stresstoleranz-Skills. (9) Antidissoziative Skills. (10) Heimliche Skills. (11) Atemübungen. (12) Körperwahrnehmung. (13) Nähe und Distanz. (14) Selbstwert. (15) Anhang (übungen - bersicht; Arbeits- und bersichtsbücher; bersicht Checkliste Erstkontakt; "Atemübungen": "Fugashebelatmung", "Mittelfingerpressatmung", "Pranayama", "Schnffelatmung", "Windmhlenatmung").
Broman-Fulks, Joshua J.; Bergquist, John J.; Hall, Christian A.; Thomas, Kelsey; Kelso, Kerry C.	2023	Incremental Validity of Cognitive-Behavioral Therapy and Acceptance and Commitment Therapy Mechanisms for Anxiety and Panic Symptomology	Journal of cognitive psychotherapy	37	1	43–62	Background: acceptance and commitment therapy (ACT) and cognitive-behavioral therapy (CBT) are empirically supported treatments for anxiety and panic disorder (PD), though they differ in their putative vulnerability and maintenance processes. The present study examined the incremental validity of several of these models' proposed core processes, including anxiety sensitivity (AS), dispositional avoidance, experiential avoidance (EA), cognitive fusion (CF), and mindfulness, as well as the interaction of the processes within each model, in the prediction of anxiety and panic symptomology. Methods: a sample of US adults (n = 316) completed self-report measures of AS, dispositional avoidance, EA, CF, mindfulness, anxiety, and PD symptoms. A series of hierarchical multiple regression analyses were conducted. Results: hierarchical regression analyses indicated that AS, dispositional avoidance, and EA predicted anxiety and panic symptoms even after controlling for one another, CF, mindfulness, and demographic variables. Although mindfulness and CF

							<p>was correlated with anxiety and panic at the univariate level, they did not predict either outcome above and beyond AS, dispositional avoidance, and EA. When interaction terms were added to the models, the interaction between AS and -dispositional avoidance was a significant predictor of panic and anxiety symptoms, whereas the interaction between EA and CF only predicted panic symptoms. None of the interactions that included mindfulness were significant predictors. Conclusions: these findings provide support the independent and interactive predictive value of traditional CBT (AS, dispositional avoidance, and AS-dispositional avoidance) and ACT (EA) processes for anxiety and panic symptoms, but raise questions about the incremental predictive utility of CF and mindfulness.</p>
Bros, Ignasi; Notó, Pere; Bulbena, Antoni	2017	Effectiveness of Short-Term Dynamic Group Psychotherapy in Primary Care for Patients with Depressive Symptoms	Clinical psychology & psychotherapy	24	4	826–834	<p>UNLABELLED</p> <p>An open prospective controlled study was designed to compare the efficacy of short-term dynamic group psychotherapy with the standard treatment in patients with depressive symptoms attended in the primary care setting. A total of 115 patients with depressive symptoms were assigned to receive psychotherapy (75 min) over 9 months (37 to 39 sessions) (n = 70) or the standard care (n = 45). Outcome measures were the differences between baseline and post-treatment in the 17-item Hamilton Depression Rating Scale (HDRS), Hamilton Anxiety Rating Scale (HAM-A) and the Short-Form Health Survey (SF-12) questionnaire in the two study groups. At the end of dynamic group psychotherapy, statistically significant improvements in the mean scores of all questionnaires were observed, whereas in control patients, significant improvements were only observed in the HDRS-17 scale and in the Mental Component</p>

							<p>Summary score of the SF-12. The mean changes after treatment were also higher in the psychotherapy group than in controls in all outcome measures, with statistically significant differences in the mean differences in favour of the psychotherapy group. In summary, implementation of short-term dynamic group psychotherapy run by experienced psychotherapists for patients with depressive symptoms attended in routine primary care centres is feasible and effective. © 2016 The Authors. Clinical Psychology & Psychotherapy published by John Wiley & Sons Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Short-term dynamic group psychotherapy was delivered as a non-pharmacological intervention to improve depressive symptoms. Statistically significant differences as compared with a control group were observed in 17-item Hamilton Depression Rating Scale (HDRS), Hamilton Anxiety Rating Scale (HAM-A) and the Short-Form Health Survey (SF-12) questionnaire. Implementation of short-term dynamic group psychotherapy run by experienced psychotherapists for patients with depressive symptoms attended in routine primary care centres is feasible and effective.</p>
Brouwer, Brenda; Bryant, Dianne; Garland, S. Jayne	2018	Effectiveness of Client-Centered "Tune-Ups" on Community Reintegration, Mobility, and Quality of Life After Stroke: A Randomized Controlled Trial	Archives of physical medicine and rehabilitation	99	7	1325–1332	<p>OBJECTIVE: To explore the effectiveness of a 2-week client-centered rehabilitation intervention (tune-up) delivered 6 months after inpatient discharge on community reintegration at 1 year in people with stroke. DESIGN: A multicenter randomized controlled trial with 2 groups: an intervention ("tune-up") group and a control group having the same exposure to assessment. SETTING: Three research laboratories. PARTICIPANTS: Participants (N=103) with hemiparetic stroke recruited from inpatient rehabilitation units at the time of</p>

							<p>discharge. INTERVENTIONS: Participants randomized to the tune-up group received 1-hour therapy sessions in their home 3times/wk for 2 weeks at 6 months postdischarge focusing on identified mobility-related goals. A second tune-up was provided at 12 months. MAIN OUTCOME MEASURES: Community reintegration measured by the Subjective Index of Physical and Social Outcome at 12 months and secondary outcomes included the Berg Balance Scale and measures of mobility and health-related quality of life up to 15 months. RESULTS: At 12 months, both groups showed significant improvement in community reintegration ($P < .05$), a trend evident at all time points, with no difference between groups (mean difference, -0.5; 95% confidence interval, -1.8 to 2.7; $P = .68$). Similarly, a main effect of time reflected improvement in mobility-related and quality of life outcomes for both groups ($P \leq .05$), but no group differences ($P \geq .30$). CONCLUSIONS: All participants in the tune-up group met or exceeded at least 1 mobility-related goal; however, the intervention did not differentially improve community reintegration. The improvements in mobility and quality of life over the 15-month postdischarge period may be secondary to high activity levels in both study groups and exposure to regular assessment.</p>
Brown, Elissa J.; Goodman, Robin F.; Cohen, Judith A.; Mannarino, Anthony P.; Chaplin, William F.	2020	An Exploratory Trial of Cognitive-Behavioral vs Client-Centered Therapies for Child-Mother	Journal of child & adolescent trauma	13	1	113-125	<p>The study was an evaluation of Trauma-Focused Cognitive-Behavioral Therapy (TF-CBT; Cohen et al. 2017) with child-caregiver dyads who experienced the death of a loved one from terrorism, using a hybrid efficacy/effectiveness design in which there were no required minimum symptom levels. Forty children ages 4-17 years old whose fathers died in the line of duty on 9/11/2001 and their mothers participated in an RCT</p>

		Dyads Bereaved from Terrorism					comparing TF-CBT and Client-Centered Therapy (CCT). At baseline, mothers' PTSD, depression, and prolonged grief symptoms were highly elevated, whereas children's were at normative levels. Using intent-to-treat analysis, condition-by-time interactions showed significantly greater symptom reduction for mothers receiving CBT than those receiving CCT. For the children, both treatments led to significant symptom improvements.
Brown, Jason; Wiendels, Samantha; Eyre, Vanessa	2019	Social justice competencies for counselling and psychotherapy: Perceptions of experienced practitioners and implications for contemporary practice	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	4	533-543	
Brown, Kirk Warren; Berry, Daniel; Eichel, Kristina; Beloborodova, Polina; Rahrig, Hadley; Britton, Willoughby B.	2022	Comparing impacts of meditation training in focused attention, open monitoring, and mindfulness-based cognitive therapy on emotion reactivity and regulation:	Psychophysiology	59	7	e14024	Commonly conducted mindfulness-based trainings such as Mindfulness-based Stress Reduction (MBSR) and Mindfulness-based Cognitive Therapy (MBCT) highlight training in two key forms of meditation: focused attention (FA) and open monitoring (OM). Largely unknown is what each of these mindfulness practices contributes to emotional and other important training outcomes. This dismantling trial compared the effects of structurally equivalent trainings in MBCT, FA, and OM on neural and subjective markers of emotional reactivity and regulation among community adults, with the aim to better understand which forms of training represent active ingredients in mindfulness trainings. Participants with

		Neural and subjective evidence from a dismantling study					<p>varying levels of depressive symptoms were randomized to one of the three trainings. Before and after each 8-week training, N = 89 participants completed a modified version of the Emotional Reactivity and Regulation Task while electroencephalographic (EEG) and self-reported emotional responses to negative, positive, and neutral photographic images were collected. Examination of EEG-based frontal alpha band asymmetry during passive viewing (reactivity) and active regulation phases of the task showed that FA and MBCT trainings produced significant leftward hemispheric shifts in frontal alpha asymmetry, commonly associated with a shift toward approach-based positive affect. Self-reported emotional responses to negative images corroborated these results, suggesting salutary changes in both emotional reactivity and regulation. OM training had limited beneficial effects, restricted to the subjective outcomes. The findings suggest that MBCT may derive its greatest benefit from training in FA rather than OM. Discussion highlights the potential value of FA training for emotional health.</p>
Brown, Lily A.; Belli, Gina; Suzuki, Noah; Capaldi, Sandy; Foa, Edna B.	2020	Reduction in Suicidal Ideation from Prolonged Exposure Therapy for Adolescents	Journal of clinical child and adolescent psychology : the official journal for the Society of Clinical Child and Adolescent Psychology, American Psychological Association, Division 53	49	5	651-659	<p>OBJECTIVE: Adolescents with posttraumatic stress disorder (PTSD) are at higher risk for suicide compared to adolescents without PTSD. This study aimed to explore whether PTSD treatment reduces suicidal ideation in adolescents and whether the degree of reduction in PTSD was associated with reduction in suicidal ideation.</p> <p>METHODS: Adolescent females with PTSD from a sexual assault (55% Black, 15.3 years, SD = 1.5) were randomized to either prolonged exposure therapy for adolescents (PE-A, n= 31) or client-centered therapy (CCT, n = 30). They reported on suicidal ideation, depression and PTSD at pre- and post-treatment, every therapy session, and follow-up, and about 40% endorsed</p>

						<p>suicidal ideation at baseline. RESULTS: There was a significant reduction in a single-item measure of suicidal ideation during treatment across all participants. The Time in Treatment × Condition interaction was significant ($p < .05$, $d = 0.52$), indicating a significantly steeper reduction in suicidal ideation in PE-A compared to in CCT. The degree of reduction in PTSD ($ps < .05$, $d = 0.26-0.54$) and depression symptoms ($ps < .05$, $d = 0.54-0.81$) in treatment and follow-up was associated with the speed of suicidal ideation reduction in treatment and follow-up. CONCLUSIONS: Adolescents randomized to PE-A had significantly faster reductions in suicidal ideation compared to those randomized to CCT. Greater reduction in PTSD and depression symptoms were associated with faster reduction in suicidal ideation. Clinically, this study demonstrates that adolescents who have suicidal ideation without current intent may benefit from PE-A.</p>
<p>Browne, Jonathan D.; Boland, David M.; Baum, Jaxon T.; Ikemiya, Kayla; Harris, Quincy; Phillips, Marin; Neufeld, Eric V.; Gomez, David; Goldman, Phillip; Dolezal, Brett A.</p>	2021	<p>Lifestyle Modification Using a Wearable Biometric Ring and Guided Feedback Improve Sleep and Exercise Behaviors: A 12-Month Randomized, Placebo-Controlled Study</p>	<p>Frontiers in physiology</p>	12	777874	<p>Purpose: Wearable biometric monitoring devices (WBMD) show promise as a cutting edge means to improve health and prevent disease through increasing accountability. By regularly providing real-time quantitative data regarding activity, sleep quality, and recovery, users may become more aware of the impact that their lifestyle has on their health. The purpose of this study was to examine the efficacy of a biometric tracking ring on improving sleep quality and increasing physical fitness over a one-year period. Methods: Fifty-six participants received a biometric tracking ring and were placed in one of two groups. One group received a 3-month interactive behavioral modification intervention (INT) that was delivered virtually via a smartphone app with guided text message feedback (GTF). The other received a 3-month non-directive wellness education control (CON). After</p>

							<p>three months, the INT group was divided into a long-term feedback group (LT-GTF) that continued to receive GTF for another nine months or short-term feedback group (ST-GTF) that stopped receiving GTF. Weight, body composition, and VO(2)max were assessed at baseline, 3months, and 12months for all participants and additionally at 6 and 9months for the ST-GTF and LT-GTF groups. To establish baseline measurements, sleep and physical activity data were collected daily over a 30-day period. Daily measurements were also conducted throughout the 12-month duration of the study. Results: Over the first 3months, the INT group had significant ($p<0.001$) improvements in sleep onset latency, daily step count, % time jogging, VO(2)max, body fat percentage, and heart rate variability (rMSSD HRV) compared to the CON group. Over the next 9months, the LT-GTF group continued to improve significantly ($p<0.001$) in sleep onset latency, daily step count, % time jogging, VO(2)max, and rMSSD HRV. The ST-GTF group neither improved nor regressed over the latter 9months except for a small increase in sleep latency. Conclusion: Using a WBMD concomitantly with personalized education, encouragement, and feedback, elicits greater change than using a WBMD alone. Additionally, the improvements achieved from a short duration of personalized coaching are largely maintained with the continued use of a WBMD.</p>
Brownlow, Janeese A.; McLean, Carmen P.; Gehrman, Philip R.; Harb,	2016	Influence of Sleep Disturbance on Global Functioning After	J. Traum. Stress (Journal of Traumatic Stress)	29	6	515–521	<p>Chronic insomnia and recurrent nightmares are prominent features of posttraumatic stress disorder (PTSD). Evidence from adult research indicates that these sleep disturbances do not respond as well to cognitive-behavioral therapies for PTSD and are associated with poorer functional outcomes. This study examined the</p>

Gerlinde C.; Ross, Richard J.; Foa, Edna B.		Posttraumatic Stress Disorder Treatment				effect of prolonged exposure therapy for adolescents versus client-centered therapy on posttraumatic sleep disturbance, and the extent to which sleep symptoms impacted global functioning among adolescents with sexual abuse-related PTSD. Participants included 61 adolescent girls seeking treatment at a rape crisis center. The Child PTSD Symptom Scale-Interview (Foa, Johnson, Feeny, & Treadwell, 2001) was used to assess PTSD diagnosis and severity of symptoms, including insomnia and nightmares. The Children's Global Assessment Scale (Shaffer et al., 1983) was used to assess global functioning. There were significant main effects of time and treatment on insomnia symptoms. Additionally, there was a main effect of time on nightmares. Results also showed that insomnia and nightmares significantly predicted poorer global functioning posttreatment ($R^2 = .21$). Despite significant improvements in posttraumatic sleep disturbance, there were still clinically significant insomnia symptoms after treatment, suggesting that additional interventions may be warranted to address residual sleep disturbance in PTSD.
Brubacher, Lorrie L.	2020	Wegweiser Emotionsfokuss ierte Paartherapie. Paare prozess- und bindungsorienti ert durch den Dschungel der Gefhle begleiten				In einem Nachschlagewerk und Manual wird ein Gesamtberblick ber die Emotionsfokussierte Paartherapie (EFT) gegeben. Mit der Bindungsbrille der EFT wird aus chaotischen Beziehungsdynamiken von Paaren der (aktuell) bestmgliche Versuch, die bedrohte Bindung zu erhalten. Diese Sichtweise ffnet den Raum zum Erkennen der ganz spezifischen Dynamik eines jeden Paares. Sie gibt auch das Ziel vor, nmlich die Wiederherstellung einer sicheren Basis zwischen den Partnern. Brugnera, Agostino; Carlucci, Samantha; Compare, Angelo; Tasca, Giorgio A.	2019	Persistence of friendly and submissive interpersonal styles among those with binge-eating disorder: Comparisons with matched controls and outcomes after group therapy	Clin. Psychol. Psychother. (Clinical psychology & psychotherapy)	26	5	603-615	Abstract Interpersonal problems play a prominent role in the development of binge-eating disorder (BED), so reducing their intensity may be a key focus of many psychological interventions. In recent years, several interpersonal treatments for BED were developed, which posit that binge eating arises to manage relational problems. However, few studies have evaluated the prototypical interpersonal problems, and no studies evaluated the longitudinal changes in interpersonal functioning after treatment within this population. We investigated the severity and prototypicality of interpersonal problems of 101 overweight women with BED from pre-group psychodynamic?interpersonal psychotherapy (GPIP) to 12 months post-GPIP. At baseline, we compared patients' interpersonal problems with two groups of matched controls (46 overweight and 49 normal weight women without a diagnosis of BED) and examined circular correlations between relational problems, depressive symptoms, and binge-eating frequency. Results showed that participants with BED had significantly higher levels of interpersonal problems compared with the matched control samples, with predominantly nonassertive and exploitable styles. Depressive symptoms were related to the presence of friendly?submissive interpersonal problems only among those with BED. Although the intensity of nonassertive interpersonal problems of patients with BED decreased post-group treatment, their profiles remained prototypically nonassertive and exploitable across all time points. Women with BED experience higher levels of interpersonal difficulties exemplified by an

							exploitable/nonassertive style that significantly improve but continue to prevail even after treatment. Clinicians might modify interventions to focus on increasing interpersonal skills and decreasing interpersonal dysfunctions among those with BED.
Bruijniks, Sanne J. E.; Meeter, Martijn; Lemmens, Lotte H. J. M.; Peeters, Frenk; Cuijpers, Pim; Huibers, Marcus J. H.	2022	Temporal and specific pathways of change in cognitive behavioral therapy (CBT) and interpersonal psychotherapy (IPT) for depression	Behaviour Research and Therapy, 2022				Abstract not released by publisher.
Bruijniks, Sanne J. E.; Meeter, Martijn; Lemmens, Lotte; Peeters, Frenk; Cuijpers, Pim; Renner, Fritz; Huibers, Marcus J. H.	2022	Mechanistic pathways of change in twice weekly versus once weekly sessions of psychotherapy for depression	Behaviour Research and Therapy, 2022				Abstract not released by publisher.
Bruijniks, Sanne J. E.; van Bronswijk, Suzanne C.; DeRubeis, Robert J.; Delgadillo,		Individual differences in response to once versus twice weekly sessions of CBT	Journal of consulting and clinical psychology	90	1		Objective: The Personalized Advantage Index (PAI) is a method to guide treatment selection by investigating which of two or more treatments is optimal for a given individual. Recently, it was shown that, on average, twice-weekly sessions of psychotherapy for depression lead to better outcomes compared to once-weekly sessions. The present study applied the PAI method to assess if

Jaime; Cuijpers, Pim; Huibers, Marcus J. H.		and IPT for depression					subgroups of patients may have a differential response to psychotherapy frequency. Method: Data came from a clinical trial (n = 200) randomizing depressed patients into different session frequencies: weekly sessions versus twice-weekly sessions. Machine-learning techniques were used to select pretreatment variables and develop a multivariable prediction model that calculated each patient's PAI. Differences in observed depression post-treatment scores (Beck Depression Inventory-II [BDI-II]) were tested between patients that received their PAI-indicated versus non-indicated session frequency. Between-group effect sizes (Cohen's d) were reported. Results: We identified prognostic indicators generally associated with lower post-treatment BDI-II regardless of treatment assignment. In addition, we identified specific demographic and psychometric features associated with differential response to weekly- versus twice-weekly therapy sessions. Observed post-treatment BDI-II scores were significantly different between individuals receiving the PAI-indicated versus non-indicated session frequency (d = .37). Conclusions: Although a higher session frequency is more effective on average, different session frequencies seem beneficial for different patients. Future studies should externally validate these findings before they can be generalized to other settings. (PsychoInfo Database Record (c) 2022 APA, all rights reserved)
Bucci, Wilma; Crisafulli, Giuseppe	2021	Linguistic Measures of the Therapeutic Process in Carl Rogers's Case of Miss Vib	Journal of psycholinguistic research	50	1	169-192	In the "parallel studies" project led by Carl Rogers at the Counseling Center of the University of Chicago over 70 years ago, measures of personality organization and other clinical ratings were applied to 10 recorded and transcribed cases. This paper applied computerized measures of the referential process to the treatment by Rogers of the client known as Miss Vib. The treatment was

							considered successful and used by Rogers to illustrate his theory of personality, and his view of the therapeutic process. Using the DAAP system, the measures were applied to therapist and client speech at embedded levels of magnification, including measures for the treatment as a whole to be compared to other treatments in the referential process data base; measures for individual sessions to show progression across the trajectory of a treatment for comparison with the clinical ratings; and measures representing word by word variation within a session to enable close examination of the process. The initial prediction concerning the relation of the referential process measures to the clinical measures was not confirmed. Close examination of pivotal sessions provided an account of the results beyond that emphasized in the client-centered approach.
Buchmeier, Amanda L.; Baker, Jonathan C.; Reuter-Yuill, Lilith M.; MacNeill, Brian R.	2018	Considerations for preference and reinforcer assessments with older adults with developmental disabilities	Behavior Analysis: Research and Practice		23 72- 94 14(Ele ctr oni c)	103-116	Assessing preference among older adults is an integral part to effective and therapeutic programming. Although much of the research on preference assessments in this population has focused on typically developing older adults, there is a dearth of research focusing on older adults with intellectual and developmental disabilities (Braddock, 1999; LeBlanc & Matson, 1997). The following case conceptualization addresses some challenges to identifying preferred stimuli and assessing reinforcers among older adults with disabilities and demonstrates the utility of a practitioner model to overcoming these barriers (Karsten, Carr, & Lepper, 2011). Budge, Stephanie L.; Chin, Mun Yuk; Minero, Laura P.	2017	Trans individuals' facilitative coping: An	Journal of Counseling Psychology	64	1		Existing research on trans individuals has primarily focused on their negative experiences and has disproportionately examined coming-out processes and identity development stages. Using a grounded theory

		analysis of internal and external processes				approach, this qualitative study sought to examine facilitative coping processes among trans-identified individuals. Facilitative coping was operationalized as processes whereby individuals seek social support, learn new skills, change behaviors to positively adapt, and find alternative means to seek personal growth and acceptance. The sample included 15 participants who self-identified with a gender identity that was different from their assigned sex at birth. Results yielded a total of nine overarching themes: Accepting Support from Others, Actions to Increase Protection, Active Engagement Throughout the Transition Process, Actively Seeking Social Interactions, Engaging in Exploration, Internal Processes Leading to Self-Acceptance, Self-Efficacy, Shifts Leading to Embracing Change and Flexibility, and Utilization of Agency. Based on the analysis, a theoretical model emerged that highlighted the importance of internal and external coping processes in facilitating gender identity development and navigating stressors among trans individuals. Clinical implications focusing on how to implement facilitative coping processes are discussed. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Budge, Stephanie L.; Guo, Eileen; Mauk, Ezra; Tebbe, Elliot A.	2021	The development of an observational coding scheme to assess transgender and nonbinary clients' reported		58	2	Trans and nonbinary individuals experience high rates of identity-based stigma and stress (minority stress) in U.S. society. Despite research empirically linking minority stress with adverse mental health outcomes, the extent to which minority stress experiences are discussed in psychotherapy and how therapists respond is unknown. The primary aim of the present study was to develop and test an observational coding scheme, the Minority Stress Experiences and Interactions (MSEI) scheme. With this scheme, observational data from psychotherapy sessions

		minority stress experiences					with 19 transgender and nonbinary adult psychotherapy client participants were coded to provide pilot data for the initial development of the MSEI coding scheme. A total of 19 clients' entire 50-min psychotherapy sessions were coded over 3 phases of psychotherapy: beginning (Session 1), middle (Session 2), and end (Session 10/11). Results indicate that the MSEI scheme was reliable for most codes. Codes revealed that all (N = 19; 100%) clients in the study reported at least 1 minority stress event (MSE) over the course of the 3 sessions, with the mean number of MSEs being 7 per client. The most frequent proximal stressor reported by clients was related to internalized stigma and the most frequent distal stressor reported by clients was prejudice. A total of 2 clients' clinical exchanges with their therapists centered on MSEs are highlighted to demonstrate the nuance of how MSEs are discussed in session, specifically regarding multiple minority identities. Implications for the current study include the need for therapist training regarding minority stress interventions and attention to power and oppression within sessions. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Budziszewska, Magdalena; Jonsson, Sofia Elisabet		Talking about climate change and eco-anxiety in psychotherapy: A qualitative analysis of patients' experiences	Psychotherapy	59	4		Citizens' worries about climate change are often realistic and legitimate. Simultaneously, these worries can also become a source of distress so severe as to impair everyday functioning and prompt someone to seek psychotherapy. These emergent phenomena are often referred to as "climate anxiety" or "climate depression" by the popular culture and by patients themselves. Psychotherapists around the world report seeing more and more patients who report that they are experiencing distress due to climate change. This article documents a study that involved engaging 10 Swedish adults who

						<p>sought help for climate change-related emotional distress in in-depth conversations about their psychotherapeutic experience. This was followed by analyzing accounts of psychotherapeutic processes to understand patients' experiences and outcomes. Interviews were examined with interpretative phenomenological analysis (IPA). Therapists' knowledge about climate change and competence in coping with it, validation of climate change-related emotions, and learning to manage these emotions were salient aspects of psychotherapy from the patients' perspective. Connecting psychotherapy to personal values and action orientation, resulting in an enhanced sense of meaning and sense of community, was also considered important. In conclusion, based on participants' experience, we offer practical guidance for practitioners. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Bumbacea, Dragos; Panaitescu, Carmen; Bumbacea, Roxana Silvia	2021	Patient and Physician Perspectives on Asthma and Its Therapy in Romania: Results of a Multicenter Survey	Medicina (Kaunas, Lithuania)	57	10	<p>Background and Objectives: Patient's behaviours, attitudes and beliefs related to asthma and its treatment were shown to influence the adherence to therapy and the level of asthma control. This survey aimed to assess the level of asthma control and patient-reported behaviours, attitudes and expectations related to their disease in Romanian patients. Materials and Methods: This cross-sectional quantitative survey was performed in February-March 2019 and enrolled 70 specialist physicians experienced in asthma management and 433 asthma patients under their care. Results: Of the 433 patients enrolled, 19.4% had mild asthma, 60.5% moderate asthma and 20.1% severe asthma. For the previous 12 months, asthma symptoms, exacerbations and emergency room visits were common in the sample analysed, with significantly higher figures in severe</p>

							<p>asthma patients ($p < 0.001$). The most important treatment goal for asthma patients was participation in all activities of daily living, while for physicians this was preventing asthma exacerbations. The valuation of the treatment goals was different between patients with severe asthma and those with mild and moderate forms. Based on the patients' responses, 3 attitude clusters were identified: empowered savvy (36.5% of the patients), pessimistic non-compliers (43.2%), and anxious strugglers (20.3%). "Empowered savvy" had the lowest frequency of severe asthma, the highest adherence to maintenance therapy and the highest level of confidence in the effectiveness of asthma medication. The opposite of this attitude cluster is the "anxious strugglers", containing more patients with severe asthma, a higher score for worries about asthma therapy and better self-reported knowledge of their treatment, contrasting with a proportion of 25% taking maintenance therapy only when having breathing difficulties. Conclusion: Asthma control in Romania remains poor, with frequent exacerbations and hospitalizations. The differences in treatment goals found between patients and physicians and between different asthma severity groups suggest the need for more patient-centred approaches.</p>

Burnette, C. Blair; Luzier, Jessica L.; Weisenmuller, Chantel M.; Boutté, Rachel L.	2022	A systematic review of sociodemographic reporting and representation in eating disorder psychotherapy treatment trials in the United States	The International journal of eating disorders	55	4	423–454	<p>OBJECTIVE Eating disorders (EDs) were once conceptualized as primarily affecting affluent, White women, a misconception that informed research and practice for many years. Abundant evidence now discredits this stereotype, but it is unclear if prevailing "evidence-based" treatments have been evaluated in samples representative of the diversity of individuals affected by EDs. Our goal was to evaluate the reporting, inclusion, and analysis of sociodemographic variables in ED psychotherapeutic treatment randomized controlled trials (RCTs) in the US through 2020.</p> <p>METHODS We conducted a systematic review of ED</p>

						<p>psychotherapeutic treatment RCTs in the US and examined the reporting and inclusion of gender identity, age, race/ethnicity, sexual orientation, and socioeconomic status (SES) of enrolled participants, as well as recruitment methods, power analyses, and discussion of limitations and generalizability.</p> <p>RESULTS</p> <p>Our search yielded 58 studies meeting inclusion criteria dating back to 1985. Reporting was at times incomplete, absent, or centered on the racial/gender majority group. No studies reported gender diverse participants, and men and people of color were underrepresented generally, with differences noted across diagnoses. A minority of papers considered sociodemographic variables in analyses or acknowledged limitations related to sample characteristics. Some progress was made across the decades, with studies increasingly providing full racial and ethnic data, and more men included over time. Although racial and ethnic diversity improved somewhat, progress appeared to stall in the last decade.</p> <p>DISCUSSION</p> <p>We summarize findings, consider context and challenges for RCT researchers, and offer suggestions for researchers, journal editors, and reviewers on improving representation, reporting, and analytic practices.</p> <p>PUBLIC SIGNIFICANCE</p> <p>Randomized controlled trials of eating disorder psychotherapeutic treatment in the US are increasingly reporting full race/ethnicity data, but information on SES is inconsistent and sexual orientation absent. White women still comprise the overwhelming majority of participants, with few men and people of color, and no gender-diverse individuals. Findings underscore the need</p>
--	--	--	--	--	--	--

						<p>to improve reporting and increase representation to ensure evidence-based treatments are effective across and within diverse groups.</p> <p>OBJETIVO</p> <p>Los trastornos de la conducta alimentaria (TCA) alguna vez se conceptualizaron como enfermedades que afectaban principalmente a las mujeres blancas, adineradas, un concepto erróneo que informó la investigación y la práctica clínica durante muchos años. Abundante evidencia ahora desacredita este estereotipo, pero no está claro si los tratamientos prevalecientes "basados en la evidencia" se han evaluado en muestras representativas de la diversidad de individuos afectados por los TCA. Nuestro objetivo fue evaluar el informe, la inclusión y el análisis de las variables sociodemográficas en los ensayos controlados aleatorios (ECA) del tratamiento psicoterapéutico para TCA en los Estados Unidos hasta 2020. MÉTODOS: Se realizó una revisión sistemática de los ECA de tratamiento psicoterapéutico de los TCA en los Estados Unidos y se examinó el informe y la inclusión de la identidad de género, la edad, la raza/etnia, la orientación sexual y el estado socioeconómico (ESE) de los participantes inscritos, así como los métodos de reclutamiento, los análisis de poder y la discusión de las limitaciones y la generalización.</p> <p>RESULTADOS</p> <p>La búsqueda arrojó 58 estudios que cumplieron los criterios de inclusión que datan de 1985. Los informes a veces eran incompletos, ausentes o centrados en el grupo mayoritario racial / de género. Ningún estudio informó participantes con diversidad de género, y los hombres y las personas de color estuvieron</p>
--	--	--	--	--	--	---

						<p>subrepresentados en general, con diferencias observadas entre los diagnósticos. Una minoría de los artículos consideró variables sociodemográficas en los análisis o reconoció limitaciones relacionadas con las características de la muestra. Se lograron algunos avances a lo largo de las décadas, con estudios que proporcionan cada vez más datos raciales y étnicos completos, y más hombres incluidos con el tiempo. Aunque la diversidad racial y étnica mejoró un poco, el progreso pareció estancarse en la última década.</p> <p>DISCUSIÓN: Resumimos los hallazgos, consideramos el contexto y los desafíos para los investigadores de ECA, y ofrecemos sugerencias para investigadores, editores de revistas y revisores sobre cómo mejorar la representación, el informe y las prácticas analíticas.</p>
<p>Burt, Joshua B.; Preller, Katrin H.; Demirtas, Murat; Ji, Jie Lisa; Krystal, John H.; Vollenweider, Franz X.; Anticevic, Alan; Murray, John D.</p>	2021	<p>Transcriptomics-informed large-scale cortical model captures topography of pharmacological neuroimaging effects of LSD</p>	eLife	10		<p>Psychoactive drugs can transiently perturb brain physiology while preserving brain structure. The role of physiological state in shaping neural function can therefore be investigated through neuroimaging of pharmacologically induced effects. Previously, using pharmacological neuroimaging, we found that neural and experiential effects of lysergic acid diethylamide (LSD) are attributable to agonism of the serotonin-2A receptor (Preller et al., 2018). Here, we integrate brain-wide transcriptomics with biophysically based circuit modeling to simulate acute neuromodulatory effects of LSD on human cortical large-scale spatiotemporal dynamics. Our model captures the inter-areal topography of LSD-induced changes in cortical blood oxygen level-dependent (BOLD) functional connectivity. These findings suggest that serotonin-2A-mediated modulation of pyramidal-neuronal gain is a circuit mechanism through which LSD alters cortical functional topography.</p>

							Individual-subject model fitting captures patterns of individual neural differences in pharmacological response related to altered states of consciousness. This work establishes a framework for linking molecular-level manipulations to systems-level functional alterations, with implications for precision medicine.
Burton, Mark S.; Sherrill, Andrew M.; Zwiebach, Liza C.; Fenton, Emily E.; Rauch, Sheila A. M.; Rothbaum, Barbara O.	2023	Consultation competencies in prolonged exposure therapy for posttraumatic stress disorder	Psychological Trauma: Theory, Research, Practice, and Policy	15	2		Introduction: The Emory University Prolonged Exposure (PE) Consultant Training Program seeks to develop a national network of competent PE consultants. Comprehensive training in empirically supported treatment (EST), such as PE, includes a didactic training followed by a period of experiential learning through consultation during real-world clinical practice (Karlin & Cross, 2014). Expert consultants are needed to meet demand as ESTs are disseminated. Method: The Emory program has developed a training model to develop 18 consultation skills within five competency domains: the consultation relationship, general psychotherapy skills, PE-specific skills, trainee barriers to delivery, and implementation. Results: The current article outlines these domains and discusses their theoretical background and applied value for PE consultant training, drawing on examples from the Emory program. Discussion: Just as manualizing therapy has allowed for EST dissemination, the operationalizing of consultation competencies can provide a first step in disseminating evidence-based consultation practice. Bushkov, F. A.; Razumov, A. N.; Sichinava, N. V.	2021	Patient-centered approach using COPM, GAS scores in	Voprosy kurortologii, fizioterapii, i lechebnoi	98	5	5-13	OBJECTIVE: To study the efficacy of the patient- and task-oriented approach and specific therapeutic exercises (TE) for the arms in patients after spinal cord injury at the cervical level. MATERIAL AND METHODS: The study included 119 patients with a history of spinal injury of

		medical rehabilitation of patients with tetraplegia after spinal cord injury	fizicheskoi kulture			<p>more than one year. They were divided into three demographically comparable groups. Group 1 patients (control) received standard of care: TE, physiotherapeutic treatment, social adaptation (SA), and massage; Group 2- standard of care and specific TE for the arms as part of the SA; Group 3-the same as Group 2 combined with the patient- and task-oriented approach (patient-selected activities were trained). Outcomes were assessed at the beginning (T(1)), end (T(2)), and at 1 year (T(3)) after a 30-day medical rehabilitation course. RESULTS: No statistically significant differences between the groups in demographic, neurological (ISCSI score), motor (FIMm, VLT scores), psychological parameters (depression, anxiety), quality of life (WHOQOL-BREF score) before the medical rehabilitation (T(1)) were observed. At the end of the medical rehabilitation course (T(2)), the increase in functional scores was 6.0±5.4 points of FIMm score, 6.0±4.6 points of VLT score in group 1; 8.0±7.6 points of FIMm score, 7.0±7.1 points of VLT score in group 2; 9.0±6.9 points of FIMm score, 8.0±7.6 points of VLT in group 3. Significant differences were found between groups 1 and 2 and 3 on the domains of «finger I» (13.6±9.64 points vs. 15.2±9.40 and 15.3±9.21 points respectively), «fingers II-V» (9.4±6.76 points vs. 11.3±6.41 and 11.6±6.76 points respectively) of VLT score; between groups 3 and 1 on the domains «self-care» (25.9±9.67 points vs. 23.1±9.8 points), «transfer» (11.7±6.21 points vs. 10.6±6.1 points) of the FIMm score, and also the group 3 patients had a higher quality of life by 3.0±1.8 points. At delayed follow-up (T(3)-T(2)), no changes of the FIMm and VLT scores were detected within groups. In group 3, 69% of problems were identified in self-care (COPM); subjective assessment of functional improvement for</p>
--	--	--	---------------------	--	--	---

							<p>COPM (T(2)-T(1)) was as follows: «performance» 4.7±1.27 points, «satisfaction» 3.8±1.63 points; for GAS the T-score at the end of rehabilitation was 1.3±0.55 points, and the greatest significance of change was noted for COPM under «performance» (ES=0.73), with the correlation coefficient between FIMm and COPM being 0.55 and 0.63 for «performance» and «satisfaction» domains, respectively. CONCLUSION: Patient- and task-oriented approach implemented by using COPM questionnaire and GAS score together with specific TE for arms is an effective method of motor medical rehabilitation of patients with posttraumatic cervical tetraplegia. This approach improves their quality of life, while parameters of subjective scores (COPM, GAS) have the same sensitivity in comparison with the conventional motor scores (FIMm, VLT).</p>
<p>Butcher, Elizabeth; Walker, Robert; Wyeth, Emma; Samaranayaka, Ari; Schollum, John; Derrett, Sarah</p>	2022	<p>Health-Related Quality of Life and Disability Among Older New Zealanders With Kidney Failure: A Prospective Study</p>	<p>Canadian journal of kidney health and disease</p>	9		<p>2054358 1221094 712</p>	<p>BACKGROUND: Disability is prevalent in individuals with kidney failure and can contribute to significantly reduced quality of life and survival. In older individuals with kidney failure, disability can be caused by a combination of factors, including issues directly related to their kidney disease and/or treatment, including weakness, low energy, and low activity. Few studies have investigated health-related quality of life (HRQoL) as a possible predictor of disability among older individuals experiencing kidney failure. OBJECTIVE: This study aimed to determine if patient-reported HRQoL, and/or other factors at baseline, predicts disability in people with kidney failure, aged ≥65 years, after 12 months of follow-up. DESIGN: The DOS65+ study was an accelerated longitudinal cohort design comprising of both cross-sectional and longitudinal components. Participants were eligible if they were aged ≥65 years, had chronic kidney</p>

						<p>disease stage 5G (CKD 5G) (estimated glomerular filtration rate (eGFR) <15 ml/min/1.73 m²), and had: commenced kidney replacement education, or were on an active conservative pathway, or were newly incident dialysis patients commencing dialysis therapy or prevalent on dialysis. SETTING: Three New Zealand District Health Board (DHB) nephrology units (Counties Manukau, Hawke's Bay, and Southern DHB) were involved in the study. PARTICIPANTS: Participants were eligible if they were aged ≥65 years, had CKD 5G (eGFR <15 ml/min/1.73 m²), and had: commenced kidney replacement education, or were on an active conservative pathway, or were newly incident dialysis patients commencing dialysis therapy or prevalent on dialysis. MEASUREMENTS: Disability and HRQoL were measured by EQ-5D-3L, a WHO Disability Assessment Schedule (WHODAS) 2.0. METHODS: Baseline and 12-month data from our longitudinal dialysis outcomes in older New Zealanders' study were analyzed to determine if HRQoL at baseline predicted disability outcomes 12 months later. RESULTS: Of the 223 participants at baseline, 157 participants completed a follow-up interview 12 months later. Individuals with "considerable disability" at baseline had a significantly (86%) higher risk of experiencing "considerable disability" at 12 months compared with those with "lesser/no disability" at baseline. Two thirds of those with ≥3 comorbidities were experiencing "considerable disability." In addition, those with problems with EQ-5D-3L self-care, EQ-5D-3L usual activities, and EQ-5D-3L anxiety/depression reported higher rates of disability. LIMITATIONS: Selection bias is likely to have been an issue in this study as participants were excluded from the follow-up interview if they had an</p>
--	--	--	--	--	--	---

							<p>intercurrent illness requiring hospitalization within 2 weeks of the survey interview or if the treating nephrologist judged that the individual's ability to take part was significantly impaired. Sample size meant there were a limited number of explanatory/confounding variables that could be investigated in the multivariable model. CONCLUSIONS: EQ-5D-3L mobility and self-care may be useful in predicting subsequent disability for individuals with CKD 5G. Although individuals with kidney failure often experience disability, previous studies have not clearly identified HRQoL or disability as predictors of later disability for individuals with kidney failure. Therefore, we would recommend the assessment of mobility and self-care, in conjunction with existing disabilities in the clinical review and pre-dialysis education of individuals with kidney failure as they approach the need for kidney replacement therapy. Trial registration: the Australian and New Zealand clinical trials registry: ACTRN12611000024943.</p>
Butcher, Howard K.	2022	Unitary Caring Science: A Hermeneutic-Phenomenological Research Method	Nursing science quarterly	35	2	148-159	<p>All phenomenological research, including descriptive phenomenological methods, are theory based. The knowledge in a discipline is built using discipline-specific methods. The purpose of this article is to develop and describe the processes of a mode of inquiry specific to caring in nursing theories housed within the unitary caring paradigm. Morgan's practical framework examining ontological-epistemological-methodological linkages was used to develop the unitary-caring hermeneutic phenomenological research method. The method is specific to conducting hermeneutic phenomenological research within Watson's unitary caring science and Smith's theory of unitary caring. The method includes a process of linking and interpreting themes generated from</p>

							the textual analysis of participant descriptions of the caring phenomena to concepts in the specific unitary caring theory that informs the researcher's a priori theoretical perspective to develop a theoretical understanding of the experience and contribute to the development of unitary caring nursing science.
Butryn, Meghan L.; Kerrigan, Stephanie; Arigo, Danielle; Raggio, Greer; Forman, Evan M.	2018	Pilot Test of an Acceptance-Based Behavioral Intervention to Promote Physical Activity During Weight Loss Maintenance	Behavioral medicine (Washington, D.C.)	44	1	77–87	Behavioral interventions for obesity reliably facilitate short-term weight loss, but weight regain is normative. A high level of aerobic exercise may promote weight loss maintenance. However, adopting and maintaining a high level of exercise is challenging, and experiential acceptance may be important. The aim of this study was to pilot test the feasibility and efficacy of an acceptance-based behavioral treatment to promote moderate-to-vigorous physical activity (MVPA) among individuals who had recently lost weight. Adults (n = 16) who had recently lost ≥ 5% of weight were provided with a 12-week, group-based treatment. At 12 weeks, complete analyses indicated that participants had increased activity 69% (completing an average of 198.27 minutes/week of bouts MVPA, i.e., episodes of at least 10 minutes in duration). Medium-to-large effect sizes were observed for changes in process measures, including experiential acceptance. Future research to test this approach using an experimental design, a larger sample, and a longer period of observation is warranted.
Buus, Niels; Kragh Jacobsen, Elise; Bojesen, Anders Bo; Bikic, Aida; Müller-Nielsen, Klaus; Aagaard,	2019	The association between Open Dialogue to young Danes in acute psychiatric crisis and their	International journal of nursing studies	91		119–127	BACKGROUND: Although most mental disorders have their onset in early life, the mental health needs of young people are often not addressed adequately. Open Dialogue is a need-adapted approach that mobilizes psychosocial resources in a crisis struck person's social network. Open Dialogue is organised as a series of network meetings and seeks to promote collaborative

<p>Jørgen; Erlangsen, Annette</p>		<p>use of health care and social services: A retrospective register-based cohort study</p>				<p>integrated care, and a non-directive psychotherapeutic stance. Its effectiveness for young people has not previously been assessed. OBJECTIVES: The aim of the study was to examine whether a Danish Open Dialogue approach directed at young people, who sought help from Child and Adolescent Mental Health Services, reduced their utilisation of psychiatric and other health services, compared to peers receiving usual psychiatric treatment. DESIGN: A retrospective register-based cohort study. METHODS: Using clinical and national register data, a cohort of patients aged 14-19 years (n = 503) enrolled from one region during 2000 to 2015 were compared to a matched comparison group from two other regions using propensity scores. Utilisation of psychiatric health services, GP services, and social markers were assessed after 1, 2, 5 and 10 year of follow-up using logistic and Poisson regression models. RESULTS: Patients receiving Open Dialogue intervention had more psychiatric outpatient treatments at one year of follow-up (RR = 1.2, CI: 1.1-1.4) than the comparison group, but not at subsequent follow-ups. Recipients of the intervention had fewer emergency psychiatric treatments (1 year follow-up: RR = 0.2, CI: 0.1-0.5; 10 years follow-up: RR = 0.5, CI: 0.3-0.8) and less use of general practitioner services (1 year follow-up: RR = 0.90, CI: 0.82-0.99; 10 years follow-up: RR = 0.85, CI: 0.78-0.92). There was no significant reduction in the number of psychiatric hospitalisation contacts or treatment days. CONCLUSIONS: Open Dialogue was significantly associated with some reduced risks of utilising health care services. These mixed results should be tested in a randomized design.</p>

<p>Buus, Niels; Ong, Ben; McCloughen, Andrea</p>	<p>2023</p>	<p>Open dialogue trainees' perspectives on learning processes and psychotherapeutic practice: A prospective focus group study</p>	<p>Family process</p>	<p>62</p>	<p>3</p>	<p>993-1005</p>	<p>Open Dialogue is a collaborative approach to mental health care emphasizing integrated services and a dialogical psychotherapy approach. Open Dialogue training programs eschew traditional didactic teaching of technical therapeutic skills in favor of more experiential learning processes. It is unclear how these training programs affect trainees and shape their perspectives on Open Dialogue. Our aim was to follow up a group of Australian Open Dialogue trainees and explore their perspectives on learning processes and psychotherapeutic practice. We utilized a prospective focus group design with data from audio-recorded focus groups convened before (n = 2) and after (n = 3) participants completing an advanced Open Dialogue training program. Data were subjected to reflective thematic analysis. We identified the theme "Extending possibilities by holding ideas lightly," which represented a universal principle that participants applied to multiple aspects of their practice, for example, favoring multiple perspectives and approaches to therapy, including those other than Open Dialogue. This theme had two sub-themes: (1) "Allowing intimacy by being aware of personal biographies" and (2) "Learning by joining others," which reflected an increased willingness by participants to reflect on and share their inner experiences and an emphasis on joint experiential exercises in the training program. "Extending possibilities by holding ideas lightly" facilitated a means of incorporating a dialogical perspective into existing practices thus avoiding the potential barriers to a wholesale implementation of Open Dialogue. Findings indicated that the participants were not learning how to practice a therapeutic technique or</p>
--	-------------	---	-----------------------	-----------	----------	-----------------	---

							propositional knowledge, but were socialized into a dialogical way of being.
Byron, Katie; Howard, Dana	2017	'Hey everybody, don't get pregnant': Zika, WHO and an ethical framework for advising	Journal of medical ethics	43	5	334–338	WHO recently issued new guidance on the prevention of sexual transmission of Zika virus. The updated guidance states that '[c]ountry health programmes should ensure that... [i]n order to prevent adverse pregnancy and fetal outcomes, men and women of reproductive age, living in areas where local transmission of Zika virus is known to occur, be correctly informed and oriented to consider delaying pregnancy'. While the media has reported this advice as WHO telling couples in Zika-affected regions to avoid pregnancy, WHO states that they are not doing that. In an interview with the New York Times, a spokesperson from WHO stated, 'it's important to understand that this is not WHO saying, "Hey everybody, don't get pregnant." It's that they should be advised about this, so they themselves can make the final decision'. In this statement, the WHO's spokesperson distinguishes between actively directing individuals to delay pregnancy and advising them, which is portrayed as a merely informative act that facilitates but does not direct an individual's final decision. This paper proposes that advising should not be understood as a purely informational and non-directive act. The choices that agencies make in what advice to offer and to whom to offer the advice are ethical choices with practical implications. We will thus lay out a framework for considering the ethical issues that arise in the context of advising and demonstrate how it can be used to evaluate the WHO guidance.
Cabaniss, Deborah L.; Cherry, Sabrina;	2017	Psychodynamic psychotherapy.					

Douglas, Carolyn J.; Schwartz, Anna		A clinical manual					
Cai, Xiaoyan; Zhou, Lu; Han, Peiying; Deng, Xiaolan; Zhu, Huanhuan; Fang, Fang; Zhang, Zhi	2021	Narrative review: recent advances in doll therapy for Alzheimer's disease	Annals of palliative medicine	10	4	4878–4881	Alzheimer's disease (AD) is a severe neurodegenerative disease which impacts the quality of life in elderly patients and imposes a significant burden to families and caregivers. The prolonged life expectancy and rapidly increasing world population significantly increased the morbidity. Although it has been widely reported that the aggregation of Beta amyloid and neurofilaments is the most significant pathological change. Currently, there is no effective drug therapy for AD, and the potential risks of pharmacotherapy remain concerns. This article reviews the recent research on Doll therapy (DT), a widely used non-drug therapy on AD patients, especially its clinical effectiveness and precautions in treating AD, with an attempt to further alleviate the mental symptoms and improve the health status of AD patients. Thus, nonpharmacological treatments of AD have become an area of intense research interest in recent years. DT is a person-centered therapy that can improve both the mental and cognitive status and the quality of life in AD patients. Although there remains ethical controversy about the DT on AD patients, its positive effect has been proved. Moreover, a standards manual is required to stipulate the range of application, the time course for treatment and withdraw the toy from the patients.
Cain, Lylli; Hilsenroth, Mark	2020	Examining the relationship between object relations and interpersonal	Clinical psychology & psychotherapy	27	5	760–769	The goal of the present study was to explore the relationship between patients' object relational functioning (Social Cognition and Object Relations Scale-Global Ratings) as rated by clinicians during the course of outpatient psychodynamic psychotherapy in a university-based clinic and patient self-reported interpersonal

		distress in a clinical sample					vulnerabilities (Inventory of Interpersonal Problems-64). Participants (n = 112) were outpatients entering treatment at a university-based psychotherapy clinic and were diagnosed primarily with mood disorders as well as Axis II relational problems and features. Participants completed the IIP-64 prior to receiving therapy, and SCORS-G ratings were based on patients' level of relational functioning during the evaluation process (i.e., the semistructured interview, follow-up and feedback) and across the first two psychotherapy sessions. Results showed a significant relationship between the IIP-64 Total score with SCORS-G Self-Esteem ($r = -.21, p < .05$) and Affective Quality of Representations ($r = -.20, p < .05$), wherein self-reported interpersonal dysfunction was greater among patients who had lower self-worth and perceived others as more malevolent. These findings suggest that patients who rated themselves as having more significant interpersonal difficulty reported more negative expectations and experiences of relationships in their psychotherapy narratives. The utility of the SCORS-G and the IIP-64 as two different avenues of assessing patient relational functioning is explored.
Cammuso, Karen; Vorderstrasse, Valerie	2020	Anxiety in autism spectrum disorder: Diagnosis and therapy	Child Adolescent Behavior (The Brown University Child and Adolescent Behavior Letter)	36	11	1-4	
Campbell, Sarah B.; Erbes, Christopher; Grubbs,	2020	Social Support Moderates the Association Between	J. Traum. Stress (Journal of Traumatic Stress)	33	4	391-400	Abstract For patients participating in trauma-focused psychotherapies for posttraumatic stress disorder (PTSD), such as cognitive processing therapy (CPT), pretreatment characteristics may moderate treatment effectiveness.

Kathleen; Fortney, John		Posttraumatic Stress Disorder Treatment Duration and Treatment Outcomes in Telemedicine- Based Treatment Among Rural Veterans					For instance, preexisting supportive relationships may encourage skill utilization or provide contrasts to maladaptive cognitive biases highlighted in trauma-focused treatments for PTSD. Such pretreatment characteristics are important to study in rural individuals, who may experience barriers to initiating and completing treatment. The aim of this study was to examine whether pretreatment social support, measured using the Medical Outcomes Study Social Support Survey, would moderate the association between CPT duration (i.e., number of sessions attended) and change in PTSD symptoms, using data from a pragmatic randomized controlled trial of a telemedicine-based collaborative care intervention for rural veterans (N = 225). Social support moderated the association between CPT duration and PTSD symptom change, $B = .016$, $SE = .006$; 95% CI [.028, .005], such that increased duration was associated with more PTSD symptom change only at average or higher levels of support. This effect was found for overall and emotional support but not tangible support. Additionally, on average, among participants who attended eight or more CPT sessions, only those at or above 1 standard deviation above the mean social support score demonstrated a reliable change in PTSD symptoms. The results indicate that the link between CPT treatment duration and treatment outcomes may be stronger for veterans with higher levels of pretreatment social support.
Can, Doğan; Marín, Rebeca A.; Georgiou, Panayiotis G.; Imel, Zac E.; Atkins, David C.;	2016	“It sounds like...”: A natural language processing approach to detecting	Journal of Counseling Psychology	63	3	343–350	The dissemination and evaluation of evidence-based behavioral treatments for substance abuse problems rely on the evaluation of counselor interventions. In Motivational Interviewing (MI), a treatment that directs the therapist to utilize a particular linguistic style, proficiency is assessed via behavioral coding—a time

Narayanan, Shrikanth S.		counselor reflections in motivational interviewing					<p>consuming, nontechnological approach. Natural language processing techniques have the potential to scale up the evaluation of behavioral treatments such as MI. We present a novel computational approach to assessing components of MI, focusing on 1 specific counselor behavior—reflections, which are believed to be a critical MI ingredient. Using 57 sessions from 3 MI clinical trials, we automatically detected counselor reflections in a maximum entropy Markov modeling framework using the raw linguistic data derived from session transcripts. We achieved 93% recall, 90% specificity, and 73% precision. Results provide insight into the linguistic information used by coders to make ratings and demonstrate the feasibility of new computational approaches to scaling up the evaluation of behavioral treatments. Cannistrà, Flavio; Piccirilli, Federico; Paolo D'Alia, Pier; Giannetti, Angelica; Piva, Lorenza; Gobbato, Ferruccio; Guzzardi, Roberta; Ghisoni, Alice; Pietrabissa, Giada	2020	Examining the Incidence and Clients' Experiences of Single Session Therapy in Italy: A Feasibility Study	ANZ J of Family Therapy (Australian and New Zealand Journal of Family Therapy)	41	3	271–282	

Cannon, Margeaux; Credé, Marcus; Kimber, Justin M.; Brunkow, Alexandria; Nelson, Rebecca; McAndrew, Lisa M.	2022	The common-sense model and mental illness outcomes: A meta-analysis	Clinical psychology & psychotherapy	29	4	1186–1202	<p>Psychotherapists can improve their patients' outcomes during and after therapy by improving patients' self-management. Patients who do not effectively manage their mental illness generally have worse outcomes. Leventhal's Common-Sense Model of Self-Regulation theorizes that patients' perceptions of their illness (illness representations) guide their self-management, influencing health outcomes. The present study quantified the relations between illness representations, self-management and outcomes for mental illnesses. We conducted a meta-analysis and included articles if they reported (1) on adults with mental illnesses and (2) the correlation between mental illness representations and mental illness outcomes. Twenty-five articles were included which represented 28 independent samples. The pattern of correlations among illness representations (identity, consequences, timeline, control, coherence and emotional representations), self-management strategies (attendance, engagement and adherence to treatment) and mental illness outcomes (symptom severity and quality of life) was consistent with analyses from previous studies of mental and physical illnesses. The results found threat-related illness representations mostly had a large relationship with worse mental illness outcomes and self-management. Protective illness representations had a small-to-large relationship with better mental illness outcomes and self-management. The results suggest patients' perceptions of their mental illness may be a critical indicator of their mental illness outcomes, including symptom severity and quality of life. This theory-driven meta-analysis supports calls for the inclusion of illness representations in psychotherapy for mental illness.</p>

Cao, Lingyun; Blackman, Jerome S.; Xu, Guangxing	2018	Societal change and language change in China: Language- switching during multilingual dynamic psychotherapy	Psychoanalytic Psychology	35	2	224–230	The use of multiple languages during psychotherapies has been noted for over 100 years, since Breuer’s famous Viennese patient, Anna O., spoke in English. In this article, the authors demonstrate the meanings of language usage to 3 Chinese people in treatment in Shanghai, China. Like many educated people in Shanghai in the 21st century, they were trilingual, in Mandarin, Shanghainese, and English. Their switches in language during treatment suggested that their current problems had been generated by culture, Chinese governmental policy, social factors, interpersonal and intrapsychic conflicts involving self-states, and the enduring effects of unresolved childhood trauma. Their language-switching was noted during therapy and proved to be useful in resolving their presenting problems. (PsycINFO Database Record (c) 2018 APA, all rights reserved)
Capaldi, Sandra; Asnaani, Anu; Zandberg, Laurie J.; Carpenter, Joseph K.; Foa, Edna B.	2016	Therapeutic Alliance during Prolonged Exposure Versus Client-Centered Therapy for Adolescent Posttraumatic Stress Disorder	Journal of clinical psychology	72	10	1026– 1036	OBJECTIVES: To examine the relationship between improvements in adolescent ratings of therapeutic alliance and reductions in posttraumatic stress disorder (PTSD) severity over time among adolescent girls during prolonged exposure therapy for adolescents (PE-A) versus client-centered therapy (CCT), as well as to examine differences in changes in alliance between treatment groups. METHOD: A total of 61 adolescent girls (aged 13-18 years) with sexual assault-related PTSD received PE-A or CCT in a randomized controlled trial. Participants rated alliance at session 3, midtreatment, and posttreatment. RESULTS: The rate of improvement in adolescent-rated alliance was greater in PE-A than CCT over the course of treatment. In addition, improvement in adolescent-rated alliance significantly contributed to improvements in PTSD (regardless of treatment condition), but not vice versa. CONCLUSIONS: Contrary to beliefs that trauma-

							focused treatments fail to establish strong therapeutic alliance in sexually abused adolescents, improvement in adolescent ratings of alliance were greater in PE-A compared to CCT, and improvements in adolescent-rated alliance were significantly associated with better treatment outcome across both types of treatments.

Carducci, Bernardo J.; Nave, Christopher S.	2020	The Wiley encyclopedia of personality and individual differences					
Carlile, Nolan; Link, Jared S.; Cowan, Allison; Sarnoski, Elizabeth G.	2019	ACTing Like a Psychiatrist	Innovations in clinical neuroscience	16	9-10	17-21	Acceptance and commitment therapy (ACT), a form of cognitive behavioral therapy, predominately focuses on addressing one's relationship with thoughts and emotions rather than attempting to alter them. The use of ACT has demonstrated efficacy in interactions with patients suffering from a variety of mental health concerns. While there are no specific criteria for the use of ACT, one compelling argument that exists in support of its use is that ACT may be more efficacious than other control-based protocols in treating experiential avoidance. Further, there is some evidence available to suggest that ACT is more effective than other active treatments for depression. Here, the six core processes of ACT therapy are discussed and the application of ACT techniques in clinical practice is explored.
Carper, Matthew M.; Silk, Jennifer S.; Ladouceur, Cecile D.;	2022	Changes in Affective Network Variability Among Youth	Child psychiatry and human development	53	3	526-537	Cognitive behavioral therapy (CBT) has been shown to be an efficacious treatment for youth anxiety, but we need to know more about the process of change. Affective network variability, or the "spread" of positive and negative emotions activated across a given time period,

Forbes, Erika E.; McMakin, Dana; Ryan, Neal; Kendall, Philip C.		Treated for Anxiety Disorders					<p>has been found to be positively associated with anxiety disorder symptomatology, but it is not yet known how this construct changes in response to intervention or its association with anxiety-focused treatment outcomes. The present study used a dynamical systems framework to model ecological momentary assessment (EMA) data collected via a cellular telephone from 114 youth aged 9-14 years (M(age) = 10.94, SD = 1.46) who were seeking treatment for a primary anxiety disorder. We examined patterns of affective network variability over time and across (a) CBT and (b) client-centered therapy (CCT) to determine whether affective network changes were specific to CBT or due to nonspecific factors. Associations between treatment outcomes and patterns of affect at pretreatment and over the course of the treatments were also examined. Results revealed significant decreases in affective network variability over the course of treatment for youth who received CBT, but not for youth who received CCT. Changes in affective network variability over the course of treatment did not predict treatment outcomes. Findings provide initial support for the dynamical systems approach to examining changes that occur during treatment. Implications and future research are discussed.</p>
Carrera, María; Cabero, Andrés; González, Sonia; Rodríguez, Nuria; García, Carlos; Hernández,	2016	Solution- focused group therapy for common mental health problems: Outcome assessment in	Psychology and psychotherapy	89	3	294–307	<p>OBJECTIVES This study aimed to assess the effectiveness of solution-focused group therapy (SFGT) for psychological distress and mild to moderate depression in a routine clinical practice setting.</p> <p>DESIGN AND METHODS A naturalistic pre/post-study involving 132 mental health service users was carried out. Clients received seven structured sessions of SFGT, and pre-therapy self-report</p>

Lara; Manjón, Javier		routine clinical practice				<p>scores (Spanish brief version of Beck Depression Inventory and Hospital Anxiety and Depression Scale) were compared with post-therapy scores. Additional data on effectiveness of intervention (discharges, clients returning for help and dropout rate) were analysed at 6, 12, and 24 months after initiating intervention and compared with a control sample (132 mental health service users, frequency-matched by local health board, clinical diagnosis, and gender to the group intervention) receiving usual care (UC: Psychotropic medication and/or individual psychotherapy).</p> <p>RESULTS</p> <p>Mean post-SFGT levels were significantly lower than mean pre-SFGT levels on each self-report measure in the SFGT sample. In addition, SFGT showed a significantly higher percentage of discharges and fewer clients returning for help than with UC.</p> <p>CONCLUSIONS</p> <p>SFGT included in routine clinical practice may enhance the effectiveness of treatment in clients who suffer from depression and/or psychological distress.</p> <p>PRACTITIONER POINTS</p> <p>Therapists could use SFGT as a brief and effective tool to deal with the most prevalent mental health problems at mental healthcare centres (MHCs) in Spain, without changing day-to-day clinical routines. SFGT might be effectively incorporated in routine clinical practice for helping people with psychological distress and depressive episodes of mild and moderate severity. This study should encourage systemic therapists and strategically oriented clinicians to continue delivering and offering outcome measures of solution-focused therapy.</p>

Carroll, Andrew; McSherry, Bernadette	2018	Making defensible decisions in the era of recovery and rights	Australasian psychiatry : bulletin of Royal Australian and New Zealand College of Psychiatrists	26	5	474-477	OBJECTIVES: Our aim was to develop a framework for clinical decision-making that can be used to take into account risk in an era of recovery and rights. CONCLUSION: We developed a framework influenced by civil liability law to develop a guide for clinical decision-making which emphasises collaboration, clarification of the available information and communication of decisions as essential components of recovery-oriented risk management.
Carrotte, Elise; Hartup, Michael; Blanchard, Michelle	2019	“It's very hard for me to say anything positive”: A qualitative investigation into borderline personality disorder treatment experiences in the Australian context	Australian Psychologist	54	6	526-535	Objective To identify in the Australian context: (a) treatment and support services that are accessed by people living with borderline personality disorder (BPD) and their carers, (b) perceived benefits and challenges associated with these services, and (c) changes these individuals would like to see with regards to service provision and access. Method This project involved semi-structured qualitative interviews with 12 participants (75% female, M age=?39.9, SD=?11.7), nine with lived experience of BPD, three carers and two identifying with both roles. Additionally, two online focus groups were conducted via online peer support communities involving 11 participants in total. Interview transcripts and focus group text were analysed thematically. Results Participants described mixed experiences across a range of treatment types, locations and intensities. Themes were: identity and discovery, (mis)communication, complexities of care, finding what works (for me), an uncertain future, and carer empowerment. Participants described community-based psychotherapy as being critical for reducing symptoms of BPD and improving quality of life, but reported challenges at the macro and micro level with regards to costs, service access, clinician factors and client factors. Experiences were often not

							aligned with a recovery model of mental health. Conclusions The current Australian mental health system is not designed to best meet the needs of people living with BPD, which remains highly stigmatised and misunderstood. Future research should consider how the system could be modified or restructured to better support recovery for these individuals and others with complex mental illness.
Carter, Allison; Loutfy, Mona; Pokomandy, Alexandra de; Colley, Guillaume; Zhang, Wendy; Sereda, Paul; O'Brien, Nadia; Proulx-Boucher, Karène; Nicholson, Valerie; Beaver, Kerrigan; Kaida, Angela	2018	Health-related quality-of-life and receipt of women-centered HIV care among women living with HIV in Canada	Women & health	58	5	498–518	We measured health-related quality of life (HRQOL) using the SF-12 among women living with HIV (WLWH) in Canada between August 2013 and May 2015. We investigated differences by perceived receipt of women-centered HIV care (WCHC), assessed using an evidence-based definition with a 5-point Likert item: "Overall, I think that the care I have received from my HIV clinic in the last year has been women-centered" (dichotomized into agree vs. disagree/neutral). Of 1308 participants, 26.3 percent were from British Columbia, 48.2 percent from Ontario, and 25.5 percent from Québec. The median age was 43 years (interquartile range = 36-51). Most (42.2 percent) were White, 29.4 percent African/Caribbean/Black, and 21.0 percent Indigenous. Overall, 53.4 percent perceived having received WCHC. Mean physical and mental HRQOL scores were 43.8 (standard deviation [SD] = 14.4) and 41.7 (SD = 14.2), respectively. Women perceiving having received WCHC had higher mean physical (44.7; SD = 14.0) and mental (43.7; SD = 14.1) HRQOL scores than those not perceiving having received WCHC (42.9; SD = 14.8 and 39.5; SD = 14.0, respectively; $p < .001$). In multivariable linear regression, perceived WCHC was associated with higher mental ($\beta = 3.48$; 95 percent confidence interval: 1.90, 5.06) but not physical HRQOL. Improving HRQOL among

							Canadian WLWH, which was lower than general population estimates, is needed, including examining the potential of WCHC as an effective model of clinical care.
Casajuana Kögel, Cristina; López-Pelayo, Hugo; Oliveras, Clara; Colom, Joan; Gual, Antoni; Balcells-Oliveró, María Mercedes	2021	The relationship between motivations for cannabis consumption and problematic use	Adicciones	33	1	31–42	INTRODUCTION: Systematic screening of problematic cannabis use does not include the motivations that lead to consumption, although from a person-centered perspective this is fundamental. The present study explores the motivations for cannabis use in adults and its relationship with cannabis use patterns and problematic use. METHOD: Adult cannabis users (previous 60 days) were recruited in the province of Barcelona (n = 468). Information on their sociodemographic data, cannabis use pattern, Cannabis Abuse Screening Test (CAST) and the main motivation for use were collected. Motivations were categorized a posteriori according to the Marijuana Motives Measures (MMM). A descriptive and inferential analysis was carried out to link the motivations to sociodemographic variables, consumption pattern and probability of suffering problematic cannabis use (CAST). RESULTS: Using cannabis to heighten positive feelings (35%), out of habit (29%) and to cope with negative feelings (25%) were the most frequent motivations. In comparison to other motivations, coping is related to a greater quantity of cannabis used (4 vs 3 joints per day, p = 0.005), higher probability of problematic cannabis use (77% vs 64%, p = 0.05), and greater social vulnerability (unemployment 56% vs 37%, p = 0.001; and low educational level 14% vs 8%, p = 0.042). CONCLUSIONS: Coping as a motivation for cannabis use is present in one out of four users and is a marker of social vulnerability, greater quantity of cannabis used and higher risk of problematic use. Patient-centered care together with preventive (emotional

							and social education) and clinical strategies (psychotherapy) can be useful for this population at higher risk.
Casey, Brieger; Webb, Margaret	2019	Imaging Journeys of Recovery and Learning: A Participatory Arts-Based Inquiry	Qualitative health research	29	6	833–845	The relationship between processes of mental health recovery and lifelong learning is an area of increasing international interest. Experiences of transformation, positive effects on self-esteem, self-insight, and empowerment have been identified regarding both endeavors. Recognition of these benefits has stimulated collaborative development of educational programs in personal development, self-efficacy, and recovery principles. The importance of evaluating this educational provision has been emphasized; however, there has been little detailed exploration of students' experiences and perceptions of recovery and learning in the context of recovery education programs. In this article, we present a participatory arts-based inquiry with 14 women, including mental health service users, who undertook a recovery training program to support their roles as mental health support workers in Ireland. Participatory visual analysis revealed three recurring themes; the interrelatedness of learning and recovery journeys, knowledge as a source of stability and rescue and the need for resilience in learning and recovery.
Caspar, Franz; Barlow, David H.; Farchione, Todd J.; Sauer?Zavala, Shannon; Murray Latin, Heather; Ellard, Kristen K.;	2019	Transdiagnostische Behandlung emotionaler Strungen. Therapeutenmanual					In einem Therapeutenmanual zur auf traditionell kognitiv-behavioralen Prinzipien basierenden transdiagnostischen Behandlung emotionaler Strungen werden neben Hintergrundinformationen ber das Behandlungsprogramm praktische Anleitungen zur Untersttzung der Behandlung und Durchfhrung der Sitzungen vermittelt. Seit ber 40 Jahren hat sich ein groer Teil der Psychotherapieforschung auf die Entwicklung spezifischer Anstze fr bestimmte Strungen konzentriert.

<p>Bullis, Jacqueline R.; Bentley, Kate H.; Boettcher, Hannah T.; Cassiello?Robbins, Clair</p>							<p>Mit dem Erfolg des strungsspezifischen Ansatzes wurden aber auch seine Grenzen deutlich. Das Kompetenzniveau, auf das hin Therapeuten in Wirksamkeitsstudien zu spezialisierten Therapieanstzen trainiert werden, knnen Therapeuten normalerweise nur fr ein oder zwei Anstze erreichen und aufrechterhalten. Die meisten Therapeuten knnen und wollen sich in der Praxis aber nicht auf nur eine oder zwei Strungen spezialisieren. Dieser Fakt sowie Komorbiditten, die eher die Regel als die Ausnahme sind, sprechen gegen eine extreme Spezialisierung. Ein Ausweg wird darin ausgemacht, die berstarke Spezialisierung wieder rckgngig zu machen und sich auf das Gemeinsame in der Behandlung einer greren Gruppe von Strungen zu besinnen. Die im Manual beschriebene transdiagnostische Behandlung emotionaler Strungen ist auf alle Angststrungen und unipolare affektive Strungen sowie andere Strungen mit starker emotionaler Beteiligung, wie etwa viele somatoforme und dissoziative Strungen, anwendbar. - Inhalt: (A) Hintergrund fr Therapeuten. (1) Einfhrung zur transdiagnostischen Behandlung emotionaler Strungen (Unified Protocol). (2) Grundprinzipien der Behandlung und bersicht des Behandlungsablaufs. (3) Zustzliche Informationen fr Therapeuten. (4) berblick zum generellen Format, Aufbau und Ablauf der Behandlung. - (B) Behandlungsmodule. (5) Sitzung 1: Funktionale Messung und Einfhrung in die Behandlung. (6) Modul 1: Ziele setzen und Motivation aufrechterhalten. (7) Modul 2: Emotionen verstehen. (8) Modul 3: Achtsame Bewusstheit fr Emotionen. (9) Modul 4: Kognitive Flexibilit. (10) Modul 5: Emotionsbezogenem Verhalten entgegenhalten. <p>Caspar, Franz; Berger, Thomas; grosse Holtforth, Martin; Babl, Anna; Heer, Sara; Lin, Mu; Sthli, Annabarbara; Gmez Penedo, Juan Martn; Holstein, Dominique; Egenolf, Yvonne; Frischknecht, Eveline; Krieger, Tobias; Ramseyer, Fabian; Regli, Daniel; Schmied, Emma; Flckiger, Christoph; Brodbeck, Jeannette; Greenberg, Les; Carver, Charles S.; Castonguay, Louis; Kramer, Ueli; Auszra, Lars; Herrmann, Imke; Belz, Martina</p>	<p>2023</p>	<p>The impact of integrating emotion focused components into psychological therapy: A randomized controlled trial</p>	<p>Journal of clinical psychology</p>	<p>79</p>	<p>2</p>	<p>296–315</p>	<p>Objectives: This paper presents a randomized controlled trial on assimilative integration, which is aimed at integrating elements from other orientations within one approach to enrich its conceptual and practical repertoire. Elements from Emotion-Focused Therapy (EFT) were integrated into a form of cognitive behavior therapy: Psychological Therapy (PT). In one treatment condition, EFT was added to PT (+EFT) with the intent to enhance therapists' working with emotions. In the other condition, concepts and interventions based on the socialpsychological self-regulation approach were added to PT (+SR). Our assumption was that the +EFT would lead to greater and deeper change, particularly in the follow-up assessments. Method: Patients (n = 104) with anxiety, depression, or adjustment disorders were randomized to the two conditions and treated by 38 therapists who self-selected between the conditions. Primary outcome was symptom severity at 12-month follow-up; secondary outcomes included several measures such as interpersonal problems and quality of life. Variables were assessed at baseline, after 8 and 16 sessions, at posttreatment, and at 6- and 12-month follow-up. Results: Contrary to our hypothesis, no significant between-group effects were found. Conclusion: The findings first suggest the difficulty of topping an already very effective approach to psychotherapy. Alternative interpretations were that the EFT training, while corresponding to regular practice in AI, was not sufficient to make a difference in outcome, or that while profiting from the enhancement of abilities for working with emotions, this was outbalanced by negative effects of difficulties related to the implementation of the new elements.</p>

Caspari, Cornelia; Ritter, Lisa	2019	Gemeinsam tragen - kann erleichtern. Eine qualitative Studie zur Psychodynamik von nonverbalen und verbalen Gruppentherapien bei Brustkrebs	Gruppenanalyse	29	2	132-147	Der folgende Artikel untersucht im Rahmen einer qualitativen Studie die Erwartungen und ngste von Brustkrebspatientinnen in einer psychodynamischen Gruppentherapie. Diese umfasst zwlf Termine mit Kunst- und Tanztherapie sowie Gesprchstherapie. Die Interviews mit den Patientinnen wurden jeweils vor und nach den Gruppentherapien erhoben und inhaltsanalytisch ausgewertet. Interessant dabei ist die Darstellung der Dynamiken innerhalb der Gruppenteilnehmerinnen und den Therapierichtungen (verbal und nonverbal). Deutlich werden auch die Zusammenhnge von gesprten ngsten, die zu Ressourcen werden knnen, wenn das Potential bzw. der Raum zum offenen Ansprechen und Durcharbeiten der schweren Gefhle gegeben wird.
Caspari, Cornelia; Ritter, Lisa; Hrtl, Kristin	2020	Warum knnen Gruppentherapien bei Krebspatienten hilfreich sein?. Eine qualitative Studie zu psychodynamischer Kunst-, Tanz- und Gruppenpsychotherapie mit Brustkrebspatientinnen	PiD - Psychotherapie im Dialog	21	2	54-57	Eine qualitative Studie zur Untersuchung der Erwartungen, ngste und Erfahrungen von Brustkrebspatientinnen in einer psychodynamischen Gruppenpsychotherapie wird vorgestellt. Drei Gruppenteilnehmerinnen im Alter von 44, 48 und 52 Jahren in unterschiedlichen Krankheitsstadien wurden vor und nach der Gruppentherapie befragt. Diese umfasste zwlf Termine mit Kunst- und Tanztherapie sowie im Wechsel psychodynamisch orientierte Gesprchstherapie. Als wesentliche Inhalte wurden die Ambivalenz der sozialen Untersttzung, der Umgang mit ngsten und Unsicherheiten sowie als hilfreich erlebte Gruppenerfahrungen thematisiert. In den Interviews mit den Patientinnen wurde deutlich, dass ngste zu Ressourcen umgewandelt werden konnten, wenn das Potenzial bzw. der Raum zum offenen Ansprechen und Durcharbeiten der schweren Gefhle gegeben wurden. Cavicchioli, Marco; Kraslavski, Alexandra; Movalli, Mariagrazia; Maffei, Cesare; Ogliari, Anna	2022	The investigation of mechanisms underlying addictive behaviors: a case-control study	Journal of addictive diseases	40	3	306–325	<p>Background: The contradictory nature of behavioral addictions has sustained a nondefinitive debate regarding their construct validity. Objective(s): The current study aims at exploring mechanisms underlying two distinct classes of behaviors-behavioral addictions characterized by core alterations in reward processing systems (ARPS) and behaviors with a main function of maladaptive coping. Methods: This case-control study included 99 treatment-seeking individuals with a primary diagnosis of alcohol use disorder (male: N = 68; female: N = 31) and 74 healthy control (HC) subjects (male: N = 38; female: N = 36). The severity of maladaptive behaviors was measured through the Shorter PROMIS Questionnaire (SPQ). Latent mechanisms were assessed by the Disinhibition Domain of the Personality Inventory for DSM-5 (PID-5-DI) and the Acceptance and Action Questionnaire-II (AAQ-II). Results: The clinical group showed higher severity of behavioral addictions than HC. This difference was not replicated for the other class of maladaptive behaviors, except for compulsive buying. Ordinal regression analysis showed that the clinical group significantly predicted SPQ scores reflecting ARPS, SPQ shopping and starving subscales. This was not replicated for the overall SPQ score capturing maladaptive coping and binge eating behaviors. Controlling for PID-5-DI and AAQ-II scores, which were significantly associated to SPQ subscales, effects of the aforementioned clinical group were not significant. Conclusions: The study highlighted distinct and common mechanisms underlying different classes of maladaptive behaviors. Results supported future neuroscience research for clarifying the role of ARPS in compulsive sex and buying in order to consider them as addictive disorders.</p>

Cavicchioli, Marco; Scalabrini, Andrea; Northoff, Georg; Mucci, Clara; Ogliari, Anna; Maffei, Cesare	2021	Dissociation and emotion regulation strategies: A meta-analytic review	Journal of psychiatric research	143		370–387	<p>OBJECTIVE: Clinical and neurobiological models posited that dissociative mechanisms might affect processes involved in emotional generation and regulation. However, there is a lack of a comprehensive theoretical framework that systematically includes dissociation within emotional functioning. METHODS: The current study aims at conducting a meta-analytic review on the relationship between dissociation and emotion regulation in order to empirically estimate to what extent dissociation is related to emotion regulation processes. The meta-analysis was based on r coefficient as effect size measure, using a random-effect approach. RESULTS: The meta-analysis included 57 independent studies for a total of 11596 individuals. Findings showed an overall moderate relationship between dissociation and emotion regulation ($r(w) = .32$; $p < .05$). The association between dissociation and emotion regulation was the same among clinical samples than non-clinical ones. Furthermore, dissociation showed moderate to large relationships with maladaptive domains of emotion regulation, namely disengagement ($r(w) = 0.34$; $p < .01$) (i.e., behavioral avoidance, experiential avoidance, thought and emotional suppression) and aversive cognitive perseveration ($r(w) = 0.38$; $p < .001$) (i.e., rumination, worry and nonacceptance). The analysis did not find significant relationship between dissociation and adaptive domain of emotional regulation (i.e., problem solving, mindfulness). CONCLUSION: Dissociation in the context of emotion regulation might be viewed as a basic neuro-mental mechanism that automatically contribute to the over-modulation of emotional states through avoidance reactions from internal and external reality. Future longitudinal studies are needed to clarify the</p>
---	------	--	---------------------------------	-----	--	---------	---

							causal relationships between dissociation and emotion regulation.
Celenza, Andrea	2022	Stance, Set, Transference: The Differentiation of Two Modes of Clinical Technique	Journal of the American Psychoanalytic Association	70	2	283–305	Comparative approaches to psychoanalytic theory are a major source of exposure to different theoretical orientations and clinical technique. However, it is not always clear what the analyst actually does when translating theory into practice. As an attempt at clarification, descriptions are provided of two listening stances or attentional sets that are associated with different modes of analytic listening. These modes reside at a relatively low level of abstraction and are experience-near. The two listening stances are (1) a directed attentional set aimed at the identification of conscious or unconscious repetitive patterns, and (2) a diffuse attentional set receptive to emergent phenomena for the purpose of elaborating unconscious fantasy. These listening modes are combined in everyday practice and usually occur in an oscillating fashion; thus, separation of these listening modes in this discussion is for heuristic purposes. At the same time, these modes are prioritized differently among various theoretical models depending on the analyst's intention and goals. They also can be correlated with different types of transferences, evoking different types of clinical material that correspond to the analyst's goals and/or to phases in treatment. Because these attentional modes are governed by different neurophysiological substrates, it is helpful for analysts to have these modes clearly differentiated in their minds, even though engaging these modes tends to be spontaneous and rapidly oscillating. Two clinical vignettes are provided that illustrate the use of these two modes of listening where one or the other is prioritized.

Centonze, Antonella; Popolo, Raffaele; MacBeth, Angus; Dimaggio, Giancarlo	2021	Building the alliance and using experiential techniques in the early phases of psychotherapy for avoidant personality disorder	Journal of clinical psychology	77	5	1219–1232	Individuals experiencing avoidant personality disorder (AvPD) tend to make sense of social interactions via maladaptive self-and other attributions. They also experience difficulties in recognizing emotions. A further feature of AvPD psychopathology is the tendency to resort to maladaptive coping strategies, such as behavioral avoidance and perfectionism. Despite its impact, psychological treatments for AvPD remains poorly investigated. Herein, we describe the first five sessions of Metacognitive Interpersonal Therapy with a 28-year-old woman, whose treatment goal was to reduce social avoidance. We describe how this goal was achieved through a combination of working through the therapeutic relationship, alongside experiential techniques such as guided imagery, rescripting, and bodily work. Through this treatment configuration, the patient was able to increase self-awareness of her own emotions, enabling her to realize that she was guided by rigid schemas; specifically seeing herself as inadequate and others as judgmental. Finally, implications for the treatment of AvPD are discussed.
Centonze, Antonella; Popolo, Raffaele; Panagou, Corinna; MacBeth, Angus; Dimaggio, Giancarlo	2023	Experiential techniques and therapeutic relationship in the treatment of narcissistic personality disorder: The case of Laura	Journal of clinical psychology	79	7	1656–1669	Experiential techniques can be used to address maladaptive interpersonal patterns in patients with personality disorders (PDs) as long as they are delivered minding about the therapeutic relationship. We present the case study of Laura, a 38-year-old woman presenting with covert narcissism, generalized anxiety disorder, depression, and complicated grief treated with metacognitive interpersonal therapy. Laura initially refused to engage in any experiential work out of fear of being judged and abandoned by her therapist. To navigate this therapeutic obstacle, the therapist focused on exploring and eventually repairing early alliance ruptures.

							Thereafter, Laura engaged in experiential work, which helped her address her narcissistic interpersonal patterns. After 2 years, Laura's symptoms and narcissistic problematic behaviors decreased. This case study can help us understand how experiential techniques can be successfully used in PD psychotherapy as long as attention to the therapy relationship is paid.
Cerbone, Armand R.	2017	Introduction: Science, Sexuality, and Psychotherapy: Shifting Paradigms	Journal of clinical psychology	73	8	926–928	This introduction presents an overview of the current issue (73, 8) of Journal of Clinical Psychology: In Session. This issue features a series of articles, with clinical cases, each presented to illustrate the challenges faced by individuals and couples whose sexual and gender identities and expressions do not comport with traditional and cultural norms. These articles also document the challenges to the therapists who treat them. Considered individually, each article underscores the need to recognize the importance of evidence in guiding psychotherapy in cases involving sexuality. The discussions in each article offer recommendations meant to help and guide psychotherapists. Considered collectively, they raise important questions and considerations about shifting paradigms of human sexuality. Implications for assessment and treatment of cases involving sexuality and gender identity are discussed and recommended.
Cereda, Emanuele; Clavé, Pere; Collins, Peter F.; Holdoway, Anne; Wischmeyer, Paul E.	2021	Recovery Focused Nutritional Therapy across the Continuum of Care: Learning from COVID-19	Nutrients	13	9		Targeted nutritional therapy should be started early in severe illness and sustained through to recovery if clinical and patient-centred outcomes are to be optimised. The coronavirus disease 2019 (COVID-19) pandemic has shone a light on this need. The literature on nutrition and COVID-19 mainly focuses on the importance of nutrition to preserve life and prevent clinical deterioration during the acute phase of illness. However, there is a lack of

							information guiding practice across the whole patient journey (e.g., hospital to home) with a focus on targeting recovery (e.g., long COVID). This review paper is of relevance to doctors and other healthcare professionals in acute care and primary care worldwide, since it addresses early, multi-modal individualised nutrition interventions across the continuum of care to improve COVID-19 patient outcomes. It is of relevance to nutrition experts and non-nutrition experts and can be used to promote inter-professional and inter-organisational knowledge transfer on the topic. The primary goal is to prevent complications and support recovery to enable COVID-19 patients to achieve the best possible nutritional, physical, functional and mental health status and to apply the learning to date from the COVID-19 pandemic to other patient groups experiencing acute severe illness.
Cerolini, Silvia; Lombardo, Caterina	2022	Training for Emotion Regulation in Patients with Insomnia Disorder				207–213	
Cerone, Victoria L.	2019	A Brief Psychodynamic and Person-Centered Approach to Address Anticipatory Loss in Acute Care Settings()	Journal of social work in end-of-life & palliative care	15	4	145–156	Palliative care addresses the biopsychosocial and spiritual distress of people with critical and chronic illness. Depending on the trajectory of an illness, a social worker in an acute care setting may have a limited number of opportunities to engage in meaningful interaction with an emotionally distressed patient. The social worker is often faced with providing care to a patient who is having the dual experience of maintaining hope for medical improvement and anticipating loss. This article offers therapeutic practice skills needed by social

							workers to address the experience of anticipatory loss in an acute care setting. Brief psychodynamic and person-centered therapy, provided in combination, are highlighted as one method to explore a patient's feelings and wishes in the face of critical illness. Case-based vignettes illustrate how five open-ended questions help mitigate suffering and heighten a patient's sense of autonomy and self-worth.
Chalker, Samantha A.; Martinez Ceren, Camila S.; Ehret, Blaire C.; Depp, Colin A.	2023	Suicide-focused group therapy: A scoping review	Crisis: The Journal of Crisis Intervention and Suicide Prevention	44	6	485–496	Background: Although there are several studies focusing on group models for therapy specific to suicidal thoughts and behaviors, scoping reviews providing an overview of these studies' findings are limited. Aims: The aim of this paper was to conduct a scoping review of group therapies that explicitly target suicidal thoughts and behaviors (i.e., suicide-focused) for adults and their suicide-related outcomes. Methods: Following the PRISMA-ScR guidelines, a literature search using PubMed, Cochrane Library, and PsycINFO to identify relevant records published between 2000 and 2021 as well as a review of reference lists from relevant records was conducted. Results: There were 14 records identified with 12 unique suicide-focused group therapies. Even with variable methodological designs, sample sizes (M = 136, SD = 98), and population targeted, all records showed reductions in suicide-related outcomes by the end of the therapy; although most were not powered to determine effectiveness. Limitations: This review only included records written in English and excluded support groups that were led by peers as the focus was on therapy groups and gray literature. Conclusions: There are few evaluated therapy groups that explicitly address suicidal thoughts and behaviors. Available data indicate suicide-focused group therapy are generally feasible, acceptable, and may

							reduce suicidal-related outcomes. This is encouraging for future research; recommendations to include randomized controlled trials of the efficacy of suicide-focused group therapy are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Chamberlin, D. Eric	2022	The Active Inference Model of Coherence Therapy	Frontiers in human neuroscience	16		955558	Coherence Therapy is an empirically derived experiential psychotherapy based on Psychological Constructivism. Symptoms are viewed as necessary output from an implicit model of the world. The therapist curates experiences and directs attention toward discovering the model. Rendered explicit, the model is juxtaposed with contradictory knowledge driving memory re-consolidation with resolution of the symptom. The Bayesian Brain views perception and action as inferential processes. Prior beliefs are combined in a generative model to explain the hidden causes of sensations through a process of Active Inference. Prior beliefs that are poor fits to the real world are suboptimal. Suboptimal priors with optimal inference produce Bayes Optimal Pathology with behavioral symptoms. The Active Inference Model of Coherence Therapy posits that Coherence Therapy is a dyadic act of therapist guided Active Inference that renders the (probable) hidden causes of a client's behavior conscious. The therapist's sustained attention on the goal of inference helps to overcome memory control bias against retrieval of the affectively charged suboptimal prior. Serial experiences cue memory retrieval and re-instantiation of the physiological/affective state that necessitates production of the symptom in a particular context. As this process continues there is a break in modularity with assimilation into broader networks of experience. Typically, the symptom produced by optimal inference with the suboptimal prior is

							experienced as unnecessary/inappropriate when taken out of the particular context. The implicit construct has been re-represented and rendered consciously accessible, by a more complex but more accurate model in which the symptom is necessary in some contexts but not others. There is an experience of agency and control in symptom creation, accompanied by the spontaneous production of context appropriate behavior. The capacity for inference has been restored. The Active Inference Model of Coherence Therapy provides a framework for Coherence Therapy as a computational process which can serve as the basis for new therapeutic interventions and experimental designs integrating biological, cognitive, behavioral, and environmental factors.

Chambers-Baltz, Stephanie; Knutson, Douglas; Becerra, Monica; Hughes, Anna; Cantu Cantu, Lizbeth; Cadaret, Michael	2021	Determined to improve: An exploration of therapist perspectives about their development	Psychotherapy	58	4	437-448	Scholars note that therapist performance is one of many factors that contribute to client treatment outcomes. Given that the performance of therapists matters, researchers have identified several methods and models for improving therapist effectiveness. However, scholars have yet to explore highly effective therapists' perspectives on their motivation to develop, the methods they use, and the impact of their efforts to develop. The present study used a consensual qualitative research (Hill & Knox, 2021) approach to explore dynamics underlying therapist development of expertise. Semistructured interviews were conducted with 12 therapists whose outcome data placed them in the top 25% of clinicians of their respective clinics, according to their supervisors. The researchers reached consensus at each stage of analysis as they organized data into domains, core ideas, and cross-analysis. Domains and corresponding subdomains were: (a) struggle with personal, external, and response to barriers subdomains, (b) therapist characteristics with striving, presence, skills, and values subdomains, and (c) development with early career, formal, feedback, relational, personal/identity subdomains. Implications for practice and areas for future research are discussed. (PsycInfo Database Record (c) 2022 APA, all rights reserved)

<p>Chan, Wilson Y. K.; Lee, Pamela P. W.; Lee, Vincent; Chan, Godfrey C. F.; Leung, Wing; Ha, S. Y.; Cheuk, Daniel K. L.</p>	<p>2021</p>	<p>Outcomes of allogeneic transplantation for hemoglobin Bart's hydrops fetalis syndrome in Hong Kong</p>	<p>Pediatric transplantation</p>	<p>25</p>	<p>6</p>	<p>e14037</p>	<p>BACKGROUND: Hemoglobin Bart's hydrops fetalis syndrome (BHFS) was once considered a fatal condition universally. Medical advances over the past three decades have resulted in increasing numbers of BHFS survivors. This retrospective review summarized local territory-wide experience and outcomes of BHFS patients who received allogeneic hematopoietic stem cell transplantation (HSCT) in Hong Kong. METHODS: All BHFS patients who underwent allogeneic HSCT in Hong Kong, either in one of the two former pediatric transplant centers (Queen Mary Hospital and Prince of Wales Hospital) on or before 2019 or in the single territory-wide pediatric transplant center (Hong Kong Children's Hospital) since 2019, from January 1, 1996, till December 31, 2020, were included. Basic demographic data, perinatal history, transplant details, long-term outcomes, and morbidities were reviewed. RESULTS: Total five allogeneic HSCT were performed in two males and three females at a median age of 22 months, which include one 8/8 matched-sibling bone marrow transplant, one 5/6 matched-sibling cord blood transplant with HLA-DR antigenic mismatch, two 12/12 matched-unrelated peripheral blood stem cell transplant (PBSCT), and one haploidentical PBSCT with TCRαβ/CD45RA depletion from maternal donor. Neutrophil and platelet engrafted (>20 × 10⁹ /L) at a median of 15 and 22 days, respectively. All achieved near full donor chimerism at 1 month. All patients survived and remained transfusion-independent without significant morbidities with median follow-up duration of 10 years. CONCLUSION: To conclude, local data demonstrated favorable outcome of allogeneic HSCT for BHFS patients, but sample number is</p>

							small. Non-directive approach in counseling and international collaboration is recommended.
Chang, Doris F.; Hung, Tiffany; Ng, Nancy; Ling, Ariane; Chen, Teddy; Cao, Yuping; Zhang, Yalin	2016	Taoist cognitive therapy: Treatment of generalized anxiety disorder in a Chinese immigrant woman	Asian American Journal of Psychology	7	3		This case report describes the application of Taoist cognitive therapy (TCT) to a 32-year old Chinese (Fujianese) American immigrant woman with generalized anxiety disorder (GAD). TCT is a manualized adaptation of an indigenous psychotherapy developed in China (Zhang & Young, 1998; Zhang et al., 2002). Mrs. Liu received 16 sessions of TCT administered in Mandarin by a Chinese American social worker in conjunction with psychopharmacologic treatment. Sources of data included case notes, transcripts of session recordings, client thought records, and a battery of standardized measures. Mrs. Liu presented with significant guilt regarding her perceived failures to fulfill her filial obligations postmigration, which resulted in constant worry about family members' health, reassurance-seeking, and controlling behavior. Her anxiety and worry were conceptualized as the result of rigid attachments to beliefs, goals, and desires that are not reflective of the natural order of the universe (Tao). Mrs. Liu was guided in reevaluating stressful situations from the perspective of 8 Taoist principles that promote collective benefit, noncompetition, moderation, acceptance, humility, flexibility, wuwei (nonaction), and harmony with the laws of nature. Clinically significant reductions in anxiety, worry, and experiential avoidance were observed after 16 sessions. However, results were attenuated by the 4-month follow-up due to acute stress surrounding her husband's deportation proceedings. This case highlights how immigration-related stressors, including transnational family separation and cultural values, can shape the experience and expression of GAD. Further, the

							positive treatment response provides some evidence of the acceptability and applicability of TCT to Chinese immigrants with GAD. (PsycINFO Database Record (c) 2016 APA, all rights reserved)
Charbonneau-Dahlen, Barbara K.	2016	Quilting a Field Pattern Portrait Using Butcher's Methodology	Journal of holistic nursing : official journal of the American Holistic Nurses' Association	34	3	253-258	The nursing profession acknowledges Martha Rogers to the foundation of nursing theory as a true visionary. Butcher developed a method that ensures scientific rigor in the application of Rogerian theory, unitary field pattern portrait (UFPP), which was used to explore new phenomenon of inquiry resulting in insights into Rogerian pandimensionality. In this intervention, an American Indian tradition, quilting, became a culturally appropriate way for a nurse to facilitate healing through the application of Rogerian theory. In Rogers's theory of the science of unitary human beings, pattern unfolding becomes a way of knowing through expansion, evolving, blossoming, revealing, and openness. Rogers's theory was used to encourage healing as an American Indian mother and deeply depressed daughter created a quilting story based on Rogerian principles: resonancy, helicy, and integrality. This aesthetic field patterning modality using Butcher's UFPP captured the intervention as clients were engaged in health patterning through the American Indian tradition of quilting. Field notes with reflective journaling as recommended by Butcher assisted in the crystallization of a UFPP drawn from Rogerian nursing theory.

Chaudhury, Pourabi; Banerjee, Debanjan	2020	"Recovering With Nature": A Review of Ecotherapy and Implications for the COVID-19 Pandemic	Frontiers in public health	8		604440	Connection with nature has been considered beneficial for psychological well-being since times of evolution. Differences in Indian and Western thoughts have viewed natural elements in different lights, varying between eco-centrism to anthropocentrism. The intrusion of technology and digitalized lives as a result of globalization has decreased connectedness with nature. Ecotherapy is a novel form of psychotherapeutic technique based on explicit environmental or ecological interventions. Social and therapeutic horticulture, animal-assisted interventions, care farming, green exercise, environmental conservation and wilderness therapy are some of the ecosystem-based approaches used in mental health. Based on the principles of positive and client-centered psychology, ecotherapy-related techniques have been shown to be effective in medical disorders like hypertension, obesity, post-surgical recovery and psychosocial conditions like depression, stress reduction, post-traumatic stress disorder (PTSD), attention deficit hyperkinetic disorder (ADHD) and adjustment disorders. The principles of ecotherapy have been integrated into other psychotherapeutic techniques for better efficacy. This review attempts provides an overview of techniques, applications and challenges related to ecotherapy in psychology. The implications of its use during the ongoing Coronavirus 2019 (COVID-19) crisis, social isolation and consequent psychosocial aftermath are also discussed.
Cheli, Simone; MacBeth, Angus; Popolo,	2020	The intertwined path of perfectionism	Journal of clinical psychology	76	11	2055–2066	Psychotherapy for obsessive-compulsive personality disorder (OCPD), where perfectionism is a defining criterion, is understudied. Despite a high prevalence few

Raffaele; Dimaggio, Giancarlo		and self-criticism in a client with obsessive-compulsive personality disorder					evidence-based treatments are available for the presentation. Here we describe the course of a 6-month program of metacognitive interpersonal therapy with an OCPD patient with prominent perfectionism and self-criticism, which were considered primary outcomes of the case study. Therapy aimed initially at increasing awareness of maladaptive interpersonal schemas and promoting a healthy self. First, behavioral experiments were used to try and counteract perfectionism. Second, experiential techniques, such as guided imagery and rescripting, were used to help the client in connect with different, healthier aspects of the self, thus increasing personal and interpersonal wellbeing. Qualitative and quantitative outcomes at the intervention end and at 1-month follow-up are summarized. Finally, we reflect on how this case study can inform treatment of perfectionism in OCPD.
Chen, Cassandra Siyun; Chan, Sally Wai-Chi; Chan, Moon Fai; Yap, Suk Foon; Wang, Wenru; Kowitlawakul, Yanika	2017	Nurses' Perceptions of Psychosocial Care and Barriers to Its Provision: A Qualitative Study	The journal of nursing research : JNR	25	6	411-418	BACKGROUND: Psychosocial care is the culturally sensitive provision of psychological, social, and spiritual care through therapeutic communication. Current evidence suggests that effective psychosocial care improves patients' health outcomes and quality of life. PURPOSE: The aim of this study was to explore nurses' perceptions and experiences in providing psychosocial care to patients and to identify the related barriers and challenges. METHODS: An exploratory qualitative design using semistructured, individual, face-to-face interviews was adopted. A purposive sample of 18 registered nurses was recruited from the geriatric, medical, and surgical wards in an acute general hospital in Singapore. Interviews were audio-recorded, transcribed, and analyzed thematically. RESULTS: Four major themes emerged: patient-centered care, communication,

							<p>interprofessional care, and barriers to psychosocial care. Nurses perceived that psychosocial care consists of providing holistic care, spiritual care, support to the patient and family members, and showing empathy. Furthermore, psychosocial care is composed of communication between nurses and the patient and family members as well as communication among nurses. In addition, psychosocial care involves collaboration between healthcare professionals as well as multidisciplinary care. Barriers that are perceived by nurses include lack of time, language barriers, being task-oriented, excessive documentation, lack of family involvement, and fear of complaints. CONCLUSIONS: This study highlighted the perceptions of nurses regarding psychosocial care and the challenges in providing this care. Future studies are needed to explore ways to overcome these barriers and to enhance nurses' competencies in providing psychosocial care. The findings indicate a need to plan future interventions to provide nurses with both skill development and support to improve their ability to integrate psychosocial care, which will improve patient outcomes.</p>
Chen, Cory K.	2016	Defiance, denial, and defining limits: Helping family caregivers of individuals with dementia distinguish the tap-out from the cop-out	Journal of Psychotherapy Integration	26	4	353–365	<p>An approach to psychotherapy that integrates cognitive-behavioral, existential, experiential, and psychodynamic perspectives can help family members caring for an individual with dementia approach the challenges and stresses of caregiving in more effective, thoughtful, and connected ways. This article focuses on the process of helping caregivers differentiate challenges that require perseverance from goals that are unrealistic, face emotions evoked when limits are reached, and stumble toward acceptance and growth. The progressive nature of dementia presents caregivers with a constant barrage of</p>

							new challenges, which demand that caregivers dynamically shift between (a) accessing grit and meaning making as fuel for perseverance and (b) recognizing their limits. While the refusal to recognize limits has been valorized by society, a failure of “limit recognition” may represent attempts to avoid painful emotions such as hopelessness. The experience of hopelessness may function as an important signal of one’s limitations and, if incorporated into caregiver experience effectively, may paradoxically allow for a broader range of possibility and creativity as limits are recognized, mourned, and accepted. I argue that the process of moving from denial to despair to acceptance is largely unwilling. The therapist’s capacity to face and transform his or her own experience of hopelessness into acceptance may be an important prerequisite to helping caregivers to do the same. Chen, Cory K.; Dognin, Joanna S.	2017	Addressing the influence of hegemonic masculinity on veterans through brief dynamic interpersonal therapy	Psychology of Men & Masculinity	18	3	238–242	This paper explores a concept of masculinity that can emerge among veterans seeking psychotherapy. Specifically, we outline the impact of hegemonic masculinity, a view of masculinity that emphasizes hierarchically defined relationships, on the psychotherapeutic process. Within the hierarchy defined by hegemonic masculinity, toughness, aggression, dominance, and control are privileged and vulnerability, dependency, and uncertainty are devalued. We discuss the adaptation of Brief Dynamic Interpersonal Therapy (DIT), an evidence-based short-term psychodynamic psychotherapy, to veterans that privilege hegemonic masculine ideals. We describe the ways that a pattern of feelings evoked in these veterans’ experiences of self and other may function as a way of avoiding anxiety-provoking

						<p>experiences such as acknowledging needs and vulnerability. In particular, we discuss the impact of these patterns on some veterans by examining their (a) reactions to distress, (b) experience in their relationships, and (c) reactions to the psychotherapeutic process. A case study is presented to illustrate the ways interpersonal patterns influenced by hegemonic masculine ideals can affect the veterans' relationships with family, health-care providers, and the psychotherapist. The case also illustrates ways that clinicians can tailor an intervention to the range of issues that emerge when this pattern arises among veterans who seek psychotherapy. (PsycINFO Database Record (c) 2019 APA, all rights reserved)</p>
Chen, Cory K.; Nehrig, Nicole; Wash, Lauren; Wang, Binhuan		The impact of brief dynamic interpersonal therapy (DIT) on veteran depression and anxiety	Psychotherapy	57	3	<p>A significant proportion of veterans continue to experience depression or anxiety following treatment with the empirically supported psychotherapies offered by the Veterans Health Administration. Continued development and testing of new treatments may be useful. Brief dynamic interpersonal therapy (DIT) is a short-term psychodynamic therapy developed for depression in the United Kingdom and is being disseminated as an alternative to cognitive behavioral therapy within the National Health Service. This study represents the first evaluation of DIT in the United States, implemented at a veterans affairs medical center for veterans with depression and/or anxiety. Electronic medical records of veterans receiving DIT from 2012 to 2018 at a New York-based veterans affairs medical center were reviewed. Linear mixed-effects models were used to analyze depression and anxiety scores collected at each session from the Patient Health Questionnaire and the Generalized Anxiety Disorder seven-item scale. Following</p>

							DIT, patients presenting with clinically significant depression and/or anxiety reported a 46% reduction in Patient Health Questionnaire-9 scores (N = 60) and a 43% reduction in Generalized Anxiety Disorder seven-item scale scores (N = 46). Large effect sizes on both measures were found (d = 1.17, 95% CI [0.88, 1.47], pd = 1.24, 95% CI [0.90, 1.58], p < .0001, respectively). DIT is a promising alternative to currently offered psychotherapies for veterans with depression and anxiety. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Chen, Jessica A.; Fortney, John C.; Bergman, Hannah E.; Browne, Kendall C.; Grubbs, Kathleen M.; Hudson, Teresa J.; Raue, Patrick J.	2020	Therapeutic alliance across trauma-focused and non-trauma-focused psychotherapies among veterans with PTSD	Psychological Services	17	4	452–460	Trauma-focused psychotherapies for posttraumatic stress disorder (PTSD) are not widely utilized. Clinicians report concerns that direct discussion of traumatic experiences could undermine the therapeutic alliance, which may negatively impact retention and outcome. Studies among adolescents with PTSD found no difference in alliance between trauma-focused and non-trauma-focused psychotherapies, but this has not been tested among adults. The present study is a secondary analysis of a randomized trial of collaborative care, also known as care management, for PTSD. We examined patient-reported therapeutic alliance among 117 veterans with PTSD who participated in cognitive processing therapy (CPT, now called CPT + A; n = 54) or non-trauma-focused supportive psychotherapy for PTSD (n = 73) at VA community outpatient clinics. We tested the hypothesis that alliance in CPT would be noninferior to (i.e., not significantly worse than) non-trauma-focused psychotherapy using patient ratings on the Revised Helping Alliance Questionnaire. Patients' therapeutic alliance scores were high across both groups (CPT: M = 5.13, SD = 0.71, 95% CI [4.96, 5.30]; non-trauma-focused

							psychotherapy: M = 4.89, SD = 0.64, 95% CI [4.73, 5.05]). The difference between groups (0.23, 95% CI [0.01, 0.48]) was less than the “noninferiority margin” based on suggested clinical cutoffs (0.58 points on a 1–6 scale). These results held even after adjusting for veterans’ demographic and clinical characteristics and change in PTSD symptoms from baseline to follow-up. Although there are concerns that direct discussion of traumatic experiences could worsen therapeutic alliance, patients report similar levels of alliance in CPT and non-trauma-focused supportive psychotherapy. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Chen, Lijie; Wang, Qi; Xu, Tianchao	2023	Working memory function in patients with major depression disorder: A narrative review	Clinical psychology & psychotherapy	30	2	281–293	Working memory (WM) deficits are recognized as serious cognitive impairment in patients with major depressive disorder (MDD). This review aims to clarify the effects of impaired WM function in patients with MDD and explore non-invasive and effective treatments that can be adopted in clinical practice. This review (1) synthesizes extant literature examining brain function and brain areas in terms of WM in individuals with depression, (2) utilizes the outcomes of the studies presented in this review to discuss the effects of impaired WM function on cognitive processing in individuals with depression, (3) integrates the treatments explored in current studies and (4) provides some suggestions for future research. We found that (1) central executive (CE) components affect the processing of WM, and this might be one of the factors influencing cognitive biases, as it is implicated in repetitive negative thinking and rumination; (2) the left dorsal anterior cingulate cortex (dACC), the left dorsolateral prefrontal cortex (DLPFC) and the regions of the default mode network (DMN) play a vital role in CE functioning; and (3) psychotherapy, cognitive training,

							exercise and physical therapy can be used as complementary treatments for MDD.
Chen, Meng-Hsiang; Lin, Hsiu-Man; Sue, Yu-Ru; Yu, Yun-Chen; Yeh, Pin-Yang	2023	Meta-analysis reveals a reduced surface area of the amygdala in individuals with attention deficit/hyperactivity disorder	Couns and Psychother Res (Counselling and Psychotherapy Research)	60	9	e14308	Abstract Despite the reported lack of structural alterations in the amygdala of individuals with attention deficit/hyperactivity disorder (ADHD) in previous meta-analyses, subsequent observational studies produced conflicting results. Through incorporating the updated data from observational studies on structural features of the amygdala in ADHD, the primary goal of this study was to examine the anatomical differences in amygdala between subjects with ADHD and their neurotypical controls. Using the appropriate keyword strings, we searched the PubMed, Embase, and Web of Science databases for English articles from inception to February 2022. Eligibility criteria included observational studies comparing the structure of the amygdala between ADHD subjects and their comparators using magnetic resonance imaging (MRI). Subgroup analyses were conducted focusing on the amygdala side, as well as the use of different scanners and approach to segmentation. The effects of other continuous variables, such as age, intelligence quotient, and male percentage, on amygdala size were also investigated. Of the 5703 participants in 16 eligible studies, 2928 were diagnosed with ADHD. Compared with neurotypical controls, subjects with ADHD had a smaller amygdala surface area (particularly in the left hemisphere) but without a significant difference in volume between the two groups. Subgroup analysis of MRI scanners and different approaches to segmentation showed no statistically significant difference. There was no significant correlation between continuous variables and amygdala size. Our results showed consistent surface morphological alterations of the amygdala, in

							particular on the left side, in subjects with ADHD. However, the preliminary findings based on the limited data available for analysis warrant future studies for verification.
Chen, Roei; Rafaeli, Eshkol; Ziv-Beiman, Sharon; Bar-Kalifa, Eran; Solomonov, Nili; Barber, Jacques P.; Peri, Tuvia; Atzil-Slonim, Dana	2020	Therapeutic technique diversity is linked to quality of working alliance and client functioning following alliance ruptures	Journal of consulting and clinical psychology	88	9	844–858	Objective: The current investigation aimed to examine the possible association between therapists' flexibility in use of therapeutic techniques from different therapy orientations (i.e., therapeutic technique diversity; TTD) and subsequent improvement in client-reported (a) global functioning, as well as (b) quality of the working alliance, following sessions in which alliance ruptures occurred. Method: Clients (n = 81) who received time-limited psychodynamic therapy in a community clinic, completed session-by-session reports of working alliance and global functioning. Therapists (n = 56) completed session-by-session reports of working alliance and their use of therapeutic techniques across different therapeutic orientations, using the Multitheoretical List of Interventions (MULTI-30). Results: We found a curvilinear association between TTD in rupture sessions and client-reported global functioning at the sessions subsequent to rupture sessions, such that moderate levels of TTD were associated with greater subsequent improvement in functioning, compared with low and high levels of TTD. However, TTD was not significantly associated with subsequent changes in the quality of working alliance. Conclusions: Our results suggest that moderate levels of TTD in the face of alliance ruptures are tied to clients' global functioning improvement during psychodynamic psychotherapy. These findings highlight the importance of further investigation of a varied delivery of therapeutic techniques, especially in the face of alliance ruptures.

Chen, Yadi; Boswell, James F.; Schwartzman, Carly M.; Iles, Brittany R.	2017	Psychotherapy clients' recalled treatment experiences: A survey of perceived evidence-based practice elements	Journal of clinical psychology	73	11	1534–1542	Abstract Evidence-based practice (EBPs) elements can be observed across treatment approaches for commonly occurring problems. Little is known about the prevalence or pervasiveness of EBP elements from the routine client's perspective. We assessed psychotherapy clients' self-reported retrospective treatment experiences with regard to common EBP elements. Participants (N = 592) were consenting university undergraduate students who accessed a web survey that included (a) demographic items; (b) an item assessing the problem domain(s) of focus during their therapy; and (c) the presence/absence of 8 EBP elements and the extent to which they were a focus of their psychotherapy. Overall, routine psychotherapy clients recalled receiving a variety of EBP elements, the most common being a focus on positive emotions. Future work should continue to focus on clients' experience of psychotherapy elements, including what was/is most and least helpful to assist in the refinement and implementation of EBPs.
Chen, Yiming; Magnin, Charline; Brunelin, Jérôme; Leaute, Edouard; Fang, Yiru; Poulet, Emmanuel	2021	Can seizure therapies and noninvasive brain stimulations prevent suicidality? A systematic review	Brain and behavior	11	5	e02144	BACKGROUND Suicide is a major public health issue and the majority of those who attempt suicide suffer from mental disorders. Beyond psychopharmacotherapy, seizure therapies and noninvasive brain stimulation interventions have been used to treat such patients. However, the effect of these nonpharmacological treatments on the suicidal ideation and incidence of suicidality remains unclear. Here, we aimed to provide an update on the effects of seizure therapies and noninvasive brain stimulation on suicidality. METHODS

							<p>We conducted a systematic review of the literature in the PubMed, EMBASE, Cochrane Central Register of Controlled Trials, Elsevier ScienceDirect, and Wiley Online Library databases using the MeSH terms "Electroconvulsive Therapy", "Magnetic Seizure Stimulation", "repetitive Transcranial Magnetic Stimulation", "transcranial Direct Current Stimulation", "Cranial Electrostimulation" and "suicide". We included studies using seizure therapies and noninvasive brain stimulation as a main intervention that evaluated suicidality, regardless of diagnosis.</p> <p>RESULTS</p> <p>Among 1,019 records screened, 26 studies met the inclusion criteria using either electroconvulsive therapy (n = 14), magnetic seizure therapy (n = 2), repetitive transcranial magnetic stimulation (n = 9), or transcranial direct current stimulation (n = 1). We observed that studies reported significant results, suggesting these techniques can be effective on the suicidal dimension of mental health pathologies, but a general statement regarding their efficacy is premature due to limitations.</p> <p>CONCLUSIONS</p> <p>Future enquiry is necessary to address methodological limitations and evaluate the long-term efficacy of these methods both alone and in combination with pharmacotherapy and/or psychotherapy.</p>
Cheng, Qi; Shi, Congrong; Yan, Chao; Ren, Zhihong; Chan, Sunny Ho-Wan; Xiong, Sijia;	2022	Sequential multiple mediation of cognitive fusion and experiential avoidance in the relationship	Anxiety, stress, and coping	35	3	354–364	<p>BACKGROUND AND OBJECTIVES: The potential mechanism by which rumination influences social anxiety through cognitive fusion and experiential avoidance proposed by the Acceptance and Commitment Therapy model has not been well-documented. This study, therefore, aimed to examine the sequential multiple mediation of the two processes. DESIGN: A</p>

Zhang, Tao; Zheng, Hong		between rumination and social anxiety among Chinese adolescents					cross-sectional survey was conducted. METHOD: A total of 233 Chinese adolescents (42.06% girls) completed a set of printed self-report questionnaires measuring rumination, cognitive fusion, experiential avoidance, and social anxiety. The SPSS macro PROCESS (model 6) was used to test a sequential mediating model. A 95% confidence interval (CI) was calculated with 5000 bootstrapping re-samples. RESULTS: Bootstrap analyses indicated that there were indirect effects of rumination on social anxiety mediated by cognitive fusion together with experiential avoidance (B = 0.098, BootSE = 0.032, CI = 0.045 to 0.170), or solely by experiential avoidance (B = 0.048, BootSE = 0.020, CI = 0.014 to 0.093). The mediation of cognitive fusion alone was not significant (B = 0.065, BootSE = 0.038, CI = -0.006 to 0.144). CONCLUSIONS: The results indicated the sequential mediating role of cognitive fusion and experiential avoidance, and the relative prominence of the latter in the association between rumination and social anxiety.
Chesin, Megan S.; Brodsky, Beth S.; Beeler, Brandon; Benjamin-Phillips, Christopher A.; Taghavi, Ida; Stanley, Barbara	2018	Perceptions of adjunctive mindfulness-based cognitive therapy to prevent suicidal behavior among high suicide-risk outpatient participants	Crisis: The Journal of Crisis Intervention and Suicide Prevention	39	6	451–460	Background: Few investigations of patient perceptions of suicide prevention interventions exist, limiting our understanding of the processes and components of treatment that may be engaging and effective for high suicide-risk patients. Aims: Building on promising quantitative data that showed that adjunct mindfulness-based cognitive therapy to prevent suicidal behavior (MBCT-S) reduced suicidal thinking and depression among high suicide-risk patients, we subjected MBCT-S to qualitative inspection by patient participants. Method: Data were provided by 15 patients who completed MBCT-S during a focus group and/or via a survey. Qualitative data were coded using thematic analysis. Themes were summarized using descriptive analysis. Results: Most

							<p>patients viewed the intervention as acceptable and feasible. Patients attributed MBCT-S treatment engagement and clinical improvement to improved emotion regulation. A minority of patients indicated that factors related to the group treatment modality were helpful. A small percentage of patients found that aspects of the treatment increased emotional distress and triggered suicidal thinking. These experiences, however, were described as fleeting and were not linked to suicidal behavior. Limitations: The sample size was small. Conclusion: Information gathered from this study may assist in refining MBCT-S and treatments to prevent suicidal behavior among high suicide-risk patients generally. Cheston, Richard; Ivanecka, Ada	2017	Individual and group psychotherapy with people diagnosed with dementia: a systematic review of the literature	International journal of geriatric psychiatry	32	1	3–31	<p>Objectives Psychotherapy provides a means of helping participants to resolve emotional threats and play an active role in their lives. Consequently, psychotherapy is increasingly used within dementia care. This paper reviews the existing evidence base for individual and group psychotherapy with people affected by dementia. Design The protocol was registered. We searched electronic databases, relevant websites and reference lists for records of psychotherapy with people affected by Alzheimer's Disease, Vascular dementia, Lewy-body dementia or a mixed condition between 1997 and 2015. We included studies of therapies which met British Association of Counselling and Psychotherapy definitions (e.g. occurs regularly, focuses on talking about life events and facilitates understand of the illness). Art therapy, Cognitive Stimulation and Rehabilitation, Life Review, Reminiscence Therapy and family therapy were excluded. Studies which included people with frontal?temporal</p>

							<p>dementia and mild cognitive impairment were excluded. Data was extracted using a bespoke form, and risk of bias assessments were carried out independently by both authors. Meta-analysis was not possible because of the heterogeneity of data. Results A total of 1397 papers were screened with 26 papers using randomised, non-randomised controlled trials or repeated measured designs being included. A broad mix of therapeutic modalities, types, lengths and settings were described, focussing largely on people with mild levels of cognitive impairment living in the community. Conclusions This study was limited to only those studies published in English. The strongest evidence supported the use of short-term group therapy after diagnosis and an intensive, multi-faceted intervention for Nursing Home residents. Many areas of psychotherapy need further research. Copyright ? 2016 John Wiley & Sons, Ltd.</p>
<p>Chew, B. H.; Vos, R. C.; Stellato, R. K.; Ismail, M.; Rutten, G. E. H. M.</p>	2018	<p>The effectiveness of an emotion-focused educational programme in reducing diabetes distress in adults with Type 2 diabetes mellitus (VEMOFIT): a cluster randomized controlled trial</p>	<p>Diabetic medicine : a journal of the British Diabetic Association</p>	35	6	750-759	<p>AIMS To evaluate the effectiveness of a brief, value-based emotion-focused educational programme (VEMOFIT) in Malay adults with Type 2 diabetes mellitus compared with a programme of active listening to participants' emotional experiences, social support and their opinion on the health clinic diabetes care services (attention control). METHODS Malay adults with severe diabetes distress [Diabetes Distress Scale (DDS-17) mean score \geq 3] were included. VEMOFIT consisted of four biweekly group sessions, a booster session after 3 months and a follow-up 6 months post intervention. The attention control programme consisted of three sessions over the same period. Outcomes included diabetes distress, depressive symptoms, self-efficacy and disease control. Required</p>

							<p>total sample size was 165.</p> <p>RESULTS</p> <p>Participants (n = 124) were randomized to either VEMOFIT (n = 53) or the attention control programme (n = 71). Participants had a mean (sd) age of 55.7 (9.7) years, median diabetes duration of 7.0 (8.0) years and mean HbA1c level of 82 mmol/mol (9.7%). The mean DDS-17 level decreased significantly in both the VEMOFIT and the attention control programmes (3.4 to 2.9 vs. 3.1 to 2.7, respectively). The adjusted between-group DDS-17 difference was not significant [-0.01, 95% confidence interval (CI) -0.38, 0.35]. The proportion of individuals with severe diabetes distress decreased in both groups, from 89% to 47% vs. 69% to 39% (odds ratio 0.88; 95% CI 0.26, 2.90). Other outcomes did not differ between groups.</p> <p>CONCLUSIONS</p> <p>Both interventions decreased diabetes distress significantly. The theory-based VEMOFIT programme was not superior to the attention control programme. The latter approach is a simpler way to decrease severe diabetes distress (Trial registration: NCT02730078; NMRR-15-1144-24803).</p>
Chew, Boon How; Vos, Rimke C.; Metzendorf, Maria-Inti; Scholten, Rob Jpm; Rutten, Guy Ehm	2017	Psychological interventions for diabetes-related distress in adults with type 2 diabetes mellitus	The Cochrane database of systematic reviews	9	9	CD011469	<p>BACKGROUND</p> <p>Many adults with type 2 diabetes mellitus (T2DM) experience a psychosocial burden and mental health problems associated with the disease. Diabetes-related distress (DRD) has distinct effects on self-care behaviours and disease control. Improving DRD in adults with T2DM could enhance psychological well-being, health-related quality of life, self-care abilities and disease control, also reducing depressive symptoms.</p> <p>OBJECTIVES</p>

						<p>To assess the effects of psychological interventions for diabetes-related distress in adults with T2DM.</p> <p>SEARCH METHODS</p> <p>We searched the Cochrane Library, MEDLINE, Embase, PsycINFO, CINAHL, BASE, WHO ICTRP Search Portal and ClinicalTrials.gov. The date of the last search was December 2014 for BASE and 21 September 2016 for all other databases.</p> <p>SELECTION CRITERIA</p> <p>We included randomised controlled trials (RCTs) on the effects of psychological interventions for DRD in adults (18 years and older) with T2DM. We included trials if they compared different psychological interventions or compared a psychological intervention with usual care. Primary outcomes were DRD, health-related quality of life (HRQoL) and adverse events. Secondary outcomes were self-efficacy, glycosylated haemoglobin A1c (HbA1c), blood pressure, diabetes-related complications, all-cause mortality and socioeconomic effects.</p> <p>DATA COLLECTION AND ANALYSIS</p> <p>Two review authors independently identified publications for inclusion and extracted data. We classified interventions according to their focus on emotion, cognition or emotion-cognition. We performed random-effects meta-analyses to compute overall estimates.</p> <p>MAIN RESULTS</p> <p>We identified 30 RCTs with 9177 participants. Sixteen trials were parallel two-arm RCTs, and seven were three-arm parallel trials. There were also seven cluster-randomised trials: two had four arms, and the remaining five had two arms. The median duration of the intervention was six months (range 1 week to 24 months), and the median follow-up period was 12 months (range 0</p>
--	--	--	--	--	--	--

						<p>to 12 months). The trials included a wide spectrum of interventions and were both individual- and group-based. A meta-analysis of all psychological interventions combined versus usual care showed no firm effect on DRD (standardised mean difference (SMD) -0.07; 95% CI -0.16 to 0.03; P = 0.17; 3315 participants; 12 trials; low-quality evidence), HRQoL (SMD 0.01; 95% CI -0.09 to 0.11; P = 0.87; 1932 participants; 5 trials; low-quality evidence), all-cause mortality (11 per 1000 versus 11 per 1000; risk ratio (RR) 1.01; 95% CI 0.17 to 6.03; P = 0.99; 1376 participants; 3 trials; low-quality evidence) or adverse events (17 per 1000 versus 41 per 1000; RR 2.40; 95% CI 0.78 to 7.39; P = 0.13; 438 participants; 3 trials; low-quality evidence). We saw small beneficial effects on self-efficacy and HbA1c at medium-term follow-up (6 to 12 months): on self-efficacy the SMD was 0.15 (95% CI 0.00 to 0.30; P = 0.05; 2675 participants; 6 trials; low-quality evidence) in favour of psychological interventions; on HbA1c there was a mean difference (MD) of -0.14% (95% CI -0.27 to 0.00; P = 0.05; 3165 participants; 11 trials; low-quality evidence) in favour of psychological interventions. Our included trials did not report diabetes-related complications or socioeconomic effects. Many trials were small and were at high risk of bias for incomplete outcome data as well as possible performance and detection biases in the subjective questionnaire-based outcomes assessment, and some appeared to be at risk of selective reporting. There are four trials awaiting further classification. These are parallel RCTs with cognition-focused and emotion-cognition focused interventions. There are another 18 ongoing trials, likely focusing on emotion-cognition or cognition, assessing interventions such as diabetes self-</p>
--	--	--	--	--	--	---

							<p>management support, telephone-based cognitive behavioural therapy, stress management and a web application for problem solving in diabetes management. Most of these trials have a community setting and are based in the USA.</p> <p>AUTHORS' CONCLUSIONS</p> <p>Low-quality evidence showed that none of the psychological interventions would improve DRD more than usual care. Low-quality evidence is available for improved self-efficacy and HbA1c after psychological interventions. This means that we are uncertain about the effects of psychological interventions on these outcomes. However, psychological interventions probably have no substantial adverse events compared to usual care. More high-quality research with emotion-focused programmes, in non-US and non-European settings and in low- and middle-income countries, is needed.</p>
Chiauzzi, Emil; Clayton, Ashley; Huh-Yoo, Jina	2020	Videoconferencing-Based Telemental Health: Important Questions for the COVID-19 Era From Clinical and Patient-Centered Perspectives	JMIR mental health	7	12	e24021	<p>The COVID-19 pandemic has intensified the search for digital approaches in mental health treatment, particularly due to patients and clinicians practicing social distancing. This has resulted in the dramatic growth of videoconferencing-based telemental health (V-TMH) services. It is critical for behavioral health providers and those in the mental health field to understand the implications of V-TMH expansion on the stakeholders who use such services, such as patients and clinicians, to provide the service that addresses both patient and clinical needs. Several key questions arise as a result, such as the following: (1) in what ways does V-TMH affect the practice of psychotherapy (ie, clinical needs), (2) to what extent are ethical and patient-centered concerns warranted in terms of V-TMH services (ie, patient needs),</p>

							and (3) how do factors related to user experience affect treatment dynamics for both the patient and therapist (ie, patient and clinical needs)? We discuss how behavioral health providers can consider the future delivery of mental health care services based on these questions, which pose strong implications for technological innovation, the adaptation of treatments to new technologies, and training professionals in the delivery of V-TMH services and other digital health interventions.
Chieffo, Daniela Pia Rosaria; Lafuenti, Letizia; Mastrilli, Ludovica; Paola, Rebecca de; Vannuccini, Sofia; Morra, Marina; Salvi, Fulvia; Boškoski, Ivo; Salutari, Vanda; Ferrandina, Gabriella; Scambia, Giovanni	2022	Medi-Cinema: A Pilot Study on Cinematherapy and Cancer as A New Psychological Approach on 30 Gynecological Oncological Patients	Cancers	14	13		Background: Several subjects affected by cancer experience a significant level of multidimensional disease. This longitudinal study aims to evaluate the effectiveness of psycho-oncological support using Cinema as an emotional mediator and to promote perceived well-being by personalized psychological treatment. Methods: Thirty women diagnosed with gynecological cancer watched 12 movies and participated in a psychotherapy group co-conducted by two psychotherapists. Patients completed nine questionnaires at T0 (baseline), T1 (3 months) and T2 (6 months). Results: Patients observed significant improvements (CORE-OM: $p < 0.001$) in psychological well-being. The results showed statistically significant differences, even in several other dimensions, such as Anxiety (STAY-Y1-2: $p < 0.001$), Empathy (BEES, $p < 0.001$), Coping (COPE: $p < 0.001$), QoL (QLQ-C30, $p: 0.026$), couple relationship (DAS, Satisfaction: $p: 0.013$; Cohesion: $p: 0.004$) and alexithymia (TAS-20, Difficulty Identifying Feeling: $p: 0.002$; Externally-Oriented Thinking: $p: 0.003$). Conclusions: The data show that cinema, as an innovative psychological approach, could be a valid instrument to support patients in oncological pathways as well as facilitating the process of recognizing

							themselves in other patients and communicating about their own feelings.
Chien, Wai Tong; Clifton, Andrew V.; Zhao, Sai; Lui, Steve	2019	Peer support for people with schizophrenia or other serious mental illness	The Cochrane database of systematic reviews	4	4	CD01088 0	<p>BACKGROUND</p> <p>Peer support provides the opportunity for peers with experiential knowledge of a mental illness to give emotional, appraisal and informational assistance to current service users, and is becoming an important recovery-oriented approach in healthcare for people with mental illness.</p> <p>OBJECTIVES</p> <p>To assess the effects of peer-support interventions for people with schizophrenia or other serious mental disorders, compared to standard care or other supportive or psychosocial interventions not from peers.</p> <p>SEARCH METHODS</p> <p>We searched the Cochrane Schizophrenia Group's Study-Based Register of Trials on 27 July 2016 and 4 July 2017. There were no limitations regarding language, date, document type or publication status.</p> <p>SELECTION CRITERIA</p> <p>We selected all randomised controlled clinical studies involving people diagnosed with schizophrenia or other related serious mental illness that compared peer support to standard care or other psychosocial interventions and that did not involve 'peer' individual/group(s). We included studies that met our inclusion criteria and reported useable data. Our primary outcomes were service use and global state (relapse).</p> <p>DATA COLLECTION AND ANALYSIS</p> <p>The authors of this review complied with the Cochrane recommended standard of conduct for data screening and collection. Two review authors independently screened the studies, extracted data and assessed the</p>

						<p>risk of bias of the included studies. Any disagreement was resolved by discussion until the authors reached a consensus. We calculated the risk ratio (RR) and 95% confidence interval (CI) for binary data, and the mean difference and its 95% CI for continuous data. We used a random-effects model for analyses. We assessed the quality of evidence and created a 'Summary of findings' table using the GRADE approach.</p> <p>MAIN RESULTS</p> <p>This review included 13 studies with 2479 participants. All included studies compared peer support in addition to standard care with standard care alone. We had significant concern regarding risk of bias of included studies as over half had an unclear risk of bias for the majority of the risk domains (i.e. random sequence generation, allocation concealment, blinding, attrition and selective reporting). Additional concerns regarding blinding of participants and outcome assessment, attrition and selective reporting were especially serious, as about a quarter of the included studies were at high risk of bias for these domains. All included studies provided useable data for analyses but only two trials provided useable data for two of our main outcomes of interest, and there were no data for one of our primary outcomes, relapse. Peer support appeared to have little or no effect on hospital admission at medium term (RR 0.44, 95% CI 0.11 to 1.75; participants = 19; studies = 1, very low-quality evidence) or all-cause death in the long term (RR 1.52, 95% CI 0.43 to 5.31; participants = 555; studies = 1, very low-quality evidence). There were no useable data for our other prespecified important outcomes: days in hospital, clinically important change in global state (improvement), clinically important change in</p>
--	--	--	--	--	--	--

							<p>quality of life for peer supporter and service user, or increased cost to society. One trial compared peer support with clinician-led support but did not report any useable data for the above main outcomes.</p> <p>AUTHORS' CONCLUSIONS</p> <p>Currently, very limited data are available for the effects of peer support for people with schizophrenia. The risk of bias within trials is of concern and we were unable to use the majority of data reported in the included trials. In addition, the few that were available, were of very low quality. The current body of evidence is insufficient to either refute or support the use of peer-support interventions for people with schizophrenia and other mental illness.</p>
Chiesa, Marco; Luyten, Patrick; Fonagy, Peter	2021	Two-year follow-up and changes in reflective functioning in specialist and nonspecialist treatment models for personality disorder	Personality disorders	12	3	249–260	<p>There is a growing body of studies linking impairments in mentalizing or reflective functioning (RF) with childhood adversity, the development of personality disorder (PD), and psychiatric morbidity. Fewer studies have investigated the purported role of changes in RF in relation to clinical outcome in treatments focusing on this capacity. Moreover, it is as yet unclear whether specialist and nonspecialist treatment models are equally effective in bringing about change in RF in conjunction with symptomatic improvement. This study aimed to investigate the association between changes in RF in 3 samples of individuals with PD treated in 2 specialist psychosocial programs (a mixed residential and community-based step-down program [RT-CBP] and a residential-only psychotherapy treatment program [RT]) and in an outpatient general psychiatric service over a 2-year period after intake into treatment. RF was assessed using the Reflective Functioning Scale scored on the Adult Attachment Interview, and clinical outcome was</p>

							assessed in terms of psychiatric distress, social adjustment, and global functioning. Changes in RF were most marked in RT-CBP compared with RT and general psychiatric service. Changes in RF explained differences between treatment models for social and global adjustment outcomes, but not for disparities in psychiatric distress. A medium-intensity treatment approach to PD such as RT-CBP was more effective in improving RF and provided a balance between psychotherapy input and efforts at social integration, by bringing patients into closer contact with their social world. Childs-Fegredo, Jasmine; Fontana, Elisa; Moran, Mary; Faulkner, Paul	2023	Yoga-integrated psychotherapy for emotion dysregulation: A pilot study	Couns and Psychother Res (Counselling and Psychotherapy Research)	23	3	638–652	
Ching, Terence H. W.; Grazioplene, Rachael; Bohner, Calvin; Kichuk, Stephen A.; DePalmer, Giuliana; D'Amico, Elizabeth; Eilbott, Jeffrey; Jankovsky, Anastasia; Burke, Michelle;	2023	Safety, tolerability, and clinical and neural effects of single-dose psilocybin in obsessive-compulsive disorder: protocol for a randomized, double-blind, placebo-	Frontiers in psychiatry	14		1178529	BACKGROUND: Psilocybin may help treat obsessive-compulsive disorder (OCD). To date, only one open-label study of psilocybin for OCD exists, necessitating further investigation with a randomized controlled design. The neural correlates of psilocybin's effects on OCD have also not been studied. OBJECTIVES: This first-of-its-kind trial aims to evaluate the feasibility, safety, and tolerability of psilocybin in the treatment of OCD, provide preliminary evidence on the effects of psilocybin on OCD symptoms, and elucidate neural mechanisms that may mediate psilocybin's effects on OCD. DESIGN: We use a randomized (1:1), double-blind, placebo-controlled, non-crossover design to examine the clinical and neural effects of either a single dose of oral psilocybin (0.25

Hokanson, Jamila; Martins, Brad; Witherow, Chelsea; Patel, Prerana; Amoroso, Lucia; Schaer, Henry; Pittenger, Christopher; Kelmendi, Benjamin		controlled, non-crossover trial					mg/kg) or active placebo-control agent (250 mg of niacin) on OCD symptoms. METHODS AND ANALYSIS: We are enrolling 30 adult participants at a single site in Connecticut, USA who have failed at least one trial of standard care treatment (medication/psychotherapy) for OCD. All participants will also receive unstructured, non-directive psychological support during visits. Aside from safety, primary outcomes include OCD symptoms over the past 24 h, assessed by the Acute Yale-Brown Obsessive-Compulsive Scale and Visual Analog Scale ratings. These are collected by blinded, independent raters at baseline and the primary endpoint of 48 h post-dosing. Total follow-up is 12 weeks post-dosing. Resting state neuroimaging data will be collected at baseline and primary endpoint. Participants randomized to placebo will be offered the chance to return for an open-label dose of 0.25 mg/kg. ETHICS STATEMENT: All participants will be required to provide written informed consent. The trial (protocol v. 5.2) was approved by the institutional review board (HIC #2000020355) and registered with ClinicalTrials.gov (NCT03356483). DISCUSSION: This study may represent an advance in our ability to treat refractory OCD, and pave the way for future studies of neurobiological mechanisms of OCD that may respond to psilocybin.
Chiu, Angela W.; Falk, Avital; Pelcovitz, Michelle; Zendegui, Elaina; Bennett, Shannon M.	2022	Considerations for implementing evidence-based practices for youth anxiety in an acute	Professional Psychology: Research and Practice		19-39-1323(Electronic),	286-294	Adolescent partial hospitalization programs (PHP) provide specialized, intensive, interdisciplinary day treatment for youth with significant psychopathology warranting a higher level of care than outpatient therapy, but less intensive than admission to an inpatient unit. Although partial hospital programs are becoming increasingly utilized for youth with severe psychiatric disorders (Del Conte et al., 2016; Leffler et al., 2017), there is scarce

		psychiatric care setting			07 35- 70 28(Pri nt)		research on the effectiveness of these programs and little is known about the extent to which evidence-based practices (EBPs) for youth are typically provided through these programs. Shortened lengths of stay, fluctuating patient acuity, diagnostic heterogeneity, and clinical complexity are significant and enduring barriers to successful implementation of EBPs in acute care facilities. As such, process descriptions of initiatives to implement EBPs in acute care settings are limited in the literature. Consequently, it is of importance to the field to elucidate the challenges of adapting EBPs for acute care contexts, strategies for managing these hurdles, strengths from which to build upon, and specific examples of what facilitates successful implementation. This article focuses on the lessons learned through a team's efforts using an implementation science framework to implement EBPs for youth anxiety in an adolescent partial hospitalization program in the context of a large academic medical center situated in a metropolitan area of the northeast. Reflecting on steps and missteps, the article offers seven considerations that may be informative for teams preparing to integrate EBPs into acute psychiatric care settings. Chmyłko-Terlikowska, Dorota; Pęska, Agnieszka; Lucci, Kamil; Bryńska, Anita	2022	Factors affecting the length of hospitalization in people diagnosed with anorexia nervosa - study review	Psychiatria polska	56	1	77-87	Anorexia nervosa is a physical and mental health condition with high mortality and long-term history. Its most characteristic symptom is a significant underweight caused and maintained by a patient who is perceived as an obese person and sets a low weight limit. The course of treatment is usually long-term, involving a large group of specialists, and, depending on the patient's condition, outpatient care, day care or - in the event of high weight loss or malnutrition complications - hospitalization for

							<p>several months is necessary. Currently, there is a tendency to shorten the length of stay in the inpatient ward of patients with AN in favor of other forms of care. The aim of this article is to collect and present the results of a small number of studies on factors affecting the length of hospitalization in the treatment of anorexia nervosa. Based on the currently available tests, the body mass index at admission should be considered as a factor significantly affecting the length of hospitalization. However, the discussion remains open and further research in this area is advisable. Clarification of the above issue may provide the basis for a more patient-oriented determination of the duration of hospital treatment. Further research on factors identified in individual studies and their relationships will also be needed.</p>
Choi, Bryan H.; Pos, Alberta E.; Magnusson, Magnus S.	2016	Emotional change process in resolving self-criticism during experiential treatment of depression	Psychotherapy research : journal of the Society for Psychotherapy Research	26	4	484-499	<p>OBJECTIVE: This study tested emotion-focused therapy (EFT) theory assumptions concerning optimal emotion schematic processing during experiential psychotherapies. Emotion schematic change was investigated in the particular problem context of resolving self-criticism, an emotion schematic vulnerability to depression identified across all major psychotherapy theories. METHOD: The sample was nine highly self-critical depressed clients who received experiential treatment (n = 5 resolved while n = 4 did not resolve their self-criticism by termination). Emotion episodes (EEs) were exhaustively sampled from five sessions across three therapy phases (early, working phase, and termination) for each client. All their EEs across therapy were coded using a process measure called the Classification of Affective-Meaning States. Three complementary analytic procedures were used to</p>

							<p>examine emotion schematic changes within and across phases of therapy: graphical/descriptive, linear mixed modelling, and THEME sequential pattern analysis. RESULTS: Convergent evidence from these analyses supported EFT theory. Good resolvers of self-criticism decreased expression of secondary emotions and increased expression of primary adaptive emotions. Good resolvers also exhibited more sequences of EEs consistent with transformation of secondary and maladaptive emotions to adaptive emotions. Future directions of this research are discussed.</p>
Chompoonimit, A.; Nualnetr, N.	2016	The impact of task-oriented client-centered training on individuals with spinal cord injury in the community	Spinal cord	54	10	849-854	<p>STUDY DESIGN: Quasi-experimental study. OBJECTIVES: The objective of this study was to evaluate the impact of an 8-week, task-oriented client-centered training (TOCCT) on physical function, perception of performance and satisfaction with the activities and achievement of training goals of individuals with spinal cord injury (SCI). SETTING: Khon Kaen, Thailand. METHODS: Participants were 12 persons with SCI living in Ubolratana District, Khon Kaen Province, Thailand. Outcome measures consisted of physical function and perception of performance and satisfaction with the activities, which were assessed at pre- and post-training periods by using the Spinal Cord Independence Measure version III and the Canadian Occupational Performance Measure, respectively. The achievement of training goals was also determined by the Goal Attainment Scale. Data were analyzed by using paired t-tests. RESULTS: The 8-week, TOCCT significantly improved physical function of the participants (P=0.001, 95% confidence interval (CI) 3.22-7.12). Another positive impact of the training was found in the perceived levels of performance and satisfaction with the activities (P=0.001, 95% CI 1.31-3.49 and 1.68-3.67,</p>

							respectively). Furthermore, at the end of the study, most of the participants could reach their expected training goals. CONCLUSION: The 8-week, TOCCT significantly improved physical function and perception of performance and satisfaction with the activities of individuals with SCI when compared with the pre-training period. The training could also help most of the participants to achieve their training goals. Future studies with randomized controlled trial and longitudinal design are suggested to reveal further benefits of such training on individuals with SCI.
Chou, Jessica L.; Patton, Rikki; Zaarur, Asif; Katafiasz, Heather; Swint, Phyllis; Dang, Yue; Feeney, Erika	2023	Understanding families impacted by opioid use: Outcomes of a therapist training program	Families, Systems, & Health				Introduction: Increasing the substance use workforce is vital in addressing the many complexities of opioid use among families. The purpose of the present research was to examine 6-month outcomes of a training program focusing on opioid use among families, for master-level family therapy (MFT) and community mental health counseling (CMHC) students. Method: In total, 58 students participated in self-reported survey assessments at baseline and 6-month follow-up across the following domains: attitudes about substance use, interpersonal professional collaboration, trainee confidence, professional quality of life, and cross-cultural counseling competence. Results: The study results indicated a significant improvement between scores on attitudes of working with families impacted by substance use disorders from baseline to follow-up. There was a significant positive change in cross-cultural competency, interprofessional competency, and trainee confidence from baseline to follow-up. Discussion: The findings contribute to extant literature by examining the potential role of participating in substance use training for graduate-level MFT and CMHC trainees and

							considerations for implementing specific substance use training components among graduate-level trainees. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Chouliara, Zoë; Karatzias, Thanos; Gullone, Angela; Ferguson, Sandra; Cosgrove, Katie; Burke Draucker, Claire	2020	Therapeutic Change in Group Therapy For Interpersonal Trauma: A Relational Framework for Research and Clinical Practice	Journal of interpersonal violence	35	15-16	2897–2916	Our understanding of therapeutic change processes in group therapy for complex interpersonal trauma has been limited. The present study aimed at addressing this gap by developing a framework of therapeutic change in this field from a survivor and therapist perspective. This is a qualitative study, which utilized semistructured individual interviews. Transcripts were analyzed using interpretative phenomenological analysis (IPA) to identify recurrent themes. A final sample of n = 16 patients and n = 5 facilitators completed the interview. Main change processes identified by survivors were as follows: self versus others, trust versus threat, confrontation versus avoidance, and "patching up" versus true healing. Therapeutic processes identified by therapist facilitators included managing group dynamics, unpredictability and uncertainty, and process versus content. The proposed framework explains therapeutic change in group therapy in relational terms, that is, therapeutic dissonance, the dynamic interaction of self and experience as well as building empathic trusting relations. The importance of managing dissonance to aid personally meaningful recovery was highlighted. These findings have implications for the usefulness of relational and person-centered approaches to clinical practice in the area of interpersonal and complex trauma, especially in the early identification, prevention, and management of dropouts.
Christophe, V.; Duprez, C.; Congard, A.;	2016	Evaluate the subjective experience of	European journal of cancer care	25	5	734–743	The impact of the disease experience on the quality of life of the relatives of patients with cancer is now well documented. However, few scales specifically address

Fournier, E.; Lesur, A.; Antoine, P.; Vanlemmens, L.		the disease and its treatment in the partners of young women with non-metastatic breast cancer					the partners' subjective quality of life. This study aims to validate a questionnaire assessing the impact of cancer on the quality of life of the partners of young women with breast cancer. Partners (n = 499) of women aged <45 when diagnosed with a non-metastatic breast cancer completed a self-reported questionnaire generated from non-directive interviews led in an initial study. The structure of the scale was examined by exploratory and confirmatory factor analyses. Internal consistency, test-retest reliability and concurrent validity were assessed. The final Partner-YW-BCI contained 36 items and assessed eight dimensions of the subjective experience of partners: (1) feeling of couple cohesion, (2) negative affectivity and apprehension about the future, (3) body image and sexuality, (4) career management, (5) deterioration of the relationships with close relatives, (6) management of child(ren) and of everyday life, (7) financial difficulties, and (8) sharing and support from close relatives. The scale showed adequate psychometric properties, and will help clinicians to identify the problems of partners and to respond to them by an optimal care management.
Chui, Harold; Chong, Eddie S. K.; Atzil-Slonim, Dana; Sahin, Zeynep; Solomonov, Nili; Minges, Mary V.; Kuprian, Nadia; Barber, Jacques P.	2021	Beyond symptom reduction: Development and validation of the Complementary Measure of Psychotherapy Outcome (COMPO)		68	5		Most measures of psychotherapy outcome focus on symptomatic change. However, clients often report other changes through therapy, such as increased self-acceptance. This study reports on the development and validation of the Complementary Measure of Psychotherapy Outcome (COMPO) that assesses different areas of psychological functioning deemed important by clients and therapists. Items were written based on a literature review of client-reported change and feedback from experienced therapists. Exploratory factor analysis was conducted on the initial 42-item COMPO

						administered to 264 psychotherapy clients. Iterative item reduction resulted in the final 12-item, four-factor solution, with factors named self-acceptance, self-knowledge, relationship quality, and consideration of others. This factor structure, along with a bifactor model that contains a general factor and the four domain-specific factors, was replicated on a sample of 571 adults in the community. The 12-item COMPO exhibits convergent validity with measures of self-esteem, insight, social support, and empathy; demonstrates 2-week test-retest reliability; and predicts life satisfaction. The 12-item COMPO was further administered to 28 clients in short-term psychodynamic therapy for depression. Except for consideration of others, COMPO subscales and total scale scores improved from pre- to posttherapy. Posttherapy COMPO scores were also higher among clients who experienced clinically significant change compared to those who did not. The COMPO was negatively associated with depressive symptoms and impairments in functioning across the three samples. The brevity of the COMPO makes it a convenient tool to supplement symptom-based measures for a more comprehensive assessment of outcome in psychotherapy. (PsycInfo Database Record (c) 2023 APA, all rights reserved)	
Chui, Harold; Li, Xu; Luk, Sarah	2022	Therapist emotion and emotional change with clients: Effects on perceived empathy and session quality	Psychotherapy		19-39-1536(Electronic),	594-605	Therapists' emotion and therapist-client emotional congruence are associated with psychotherapy process and outcome. However, their pre-session emotional states are not consistently accounted for across studies, and the underlying mechanism is unclear. This study introduces the concepts of directional correspondence (DC), where therapists' and clients' emotions move in a similar direction from pre to post-session, and absolute

					00 33- 32 04(Pri nt)		<p>agreement (AA), where therapist and client become closer in emotions from pre to postsession, to examine congruence in emotional change in therapist and client from pre to postsession. In addition, clients' perception of therapist empathy was investigated as a mediator between therapists' emotion/therapist–client emotional congruence and session outcome. Sixty nine clients and 49 therapists participated in this study over the course of therapy (593 sessions in total). They rated their emotions before and after each session, and clients rated therapist empathy and session quality after each session. Multilevel models showed that therapist pre-session emotions, therapist–client pre-session emotional similarity, and DC did not predict therapist empathy and session quality. However, AA predicted better therapist empathy, which in turn predicted better session quality. The partial mediation path was also stronger when therapist and client had more dissimilar pre-session emotions. Thus, clients may rate a session based on their perception of therapist empathy, which may reflect therapist and client moving toward more similar emotions over a session. In addition, the positive effect of therapist and client growing closer in emotions is especially pronounced when they start sessions in different emotional states. Implications of the findings are discussed. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Chui, Harold; McGann, Kevin J.; Ziemer, Kathryn S.; Hoffman, Mary	2018	Trainees' use of supervision for therapy with sexual minority clients: A qualitative study	Journal of Counseling Psychology	65	1	36–50	In the supervision literature, research on sexual orientation considerations often focuses on sexual minority supervisees and less often on their work with sexual minority clients. Yet both heterosexual and sexual minority supervisees serve sexual minority clients and may have different supervision needs. Twelve predoctoral

Ann; Stahl, Jessica							interns from 12 APA-accredited counseling center internships were interviewed about how they made use of supervision for their work with a sexual minority client. The sample consisted of 6 heterosexual-identified supervisees and 6 supervisees who identified as lesbian, gay, or queer (LGQ). Data were analyzed using consensual qualitative research. All participants reported positive gains from supervision that carried over to their work with heterosexual and sexual minority clients, even when not all supervisors disclosed or discussed their own sexual orientation. Heterosexual supervisees used supervision to ensure that their heterosexuality does not interfere with an affirmative experience for their sexual minority client, whereas LGQ supervisees used supervision to explore differences in sexual identity development between themselves and their client to minimize the negative impact of overidentification. Thus, affirmative supervision may unfold with different foci depending on supervisees' sexual identity. Implications for training and supervision are discussed. Cioffi, Camille C.; Browning O'Hagan, Anastasia M.; Halvorson, Sven; DeGarmo, David S.	2023	A randomized controlled trial to improve fathering among fathers with substance use disorders: Fathering in recovery intervention	Journal of Family Psychology	37	8	1303–1314	In early recovery for substance use disorders (SUDs), fathers may experience a desire to become more active in their role as a parent but may need support in using effective parenting strategies. Parent management training programs may be effective for fathers in recovery from SUD as they have been shown to improve parenting knowledge, self-efficacy, parenting practices, and child behavior, as well as decrease parent substance use. Using the Parent Management Training-Oregon model, we adapted a video-based program for text delivery to fathers in their first year of recovery from SUD, the fathering in recovery (FIR) intervention. In this pilot study, we

						randomized 41 fathers to control or 6 weeks of video content and three brief coaching calls and assessed outcomes in the parenting, child, and substance domains at baseline, 6-week, and 4-month follow-ups. We found FIR was effective for improving parenting knowledge, fathering efficacy, and in reducing fathers' ineffective parenting. The intervention showed promise for reducing child behavior problems. While larger studies are needed to replicate and build on these FIR findings, our data suggest that FIR holds promise for improving the lives of fathers and their families affected by SUD. Cipriani, Andrea; Seedat, Soraya; Milligan, Lea; Salanti, Georgia; Macleod, Malcolm; Hastings, Janna; Thomas, James; Michie, Susan; Furukawa, Toshi A.; Gilbert, David; Soares-Weiser, Karla; Moreno, Carmen; Leucht, Stefan; Egger, Matthias; Mansoori, Parisa; Barker, James M.; Sifakis,	2023	New living evidence resource of human and non-human studies for early intervention and research prioritisation in anxiety, depression and psychosis	BMJ mental health	26	1	In anxiety, depression and psychosis, there has been frustratingly slow progress in developing novel therapies that make a substantial difference in practice, as well as in predicting which treatments will work for whom and in what contexts. To intervene early in the process and deliver optimal care to patients, we need to understand the underlying mechanisms of mental health conditions, develop safe and effective interventions that target these mechanisms, and improve our capabilities in timely diagnosis and reliable prediction of symptom trajectories. Better synthesis of existing evidence is one way to reduce waste and improve efficiency in research towards these ends. Living systematic reviews produce rigorous, up-to-date and informative evidence summaries that are particularly important where research is emerging rapidly, current evidence is uncertain and new findings might change policy or practice. Global Alliance for Living Evidence on aNxiety, depressiOn and pSychosis (GALENOS) aims to tackle the challenges of mental health science research by cataloguing and evaluating the full spectrum of relevant scientific research including

<p>Spyridon; Ostinelli, Edoardo Giuseppe; McCutcheon, Robert; Wright, Simonne; Simpson, Matilda; Elugbadebo, Olufisayo; Chiocchia, Virginia; Tonia, Thomy; Elgarf, Rania; Kurtulmus, Ayse; Sena, Emily; Simple, Ouma; Boyce, Niall; Chung, Sophie; Sharma, Anjuli; Wolpert, Miranda; Potts, Jennifer; Elliott, Julian H.</p>						<p>both human and preclinical studies. GALENOS will also allow the mental health community-including patients, carers, clinicians, researchers and funders-to better identify the research questions that most urgently need to be answered. By creating open-access datasets and outputs in a state-of-the-art online resource, GALENOS will help identify promising signals early in the research process. This will accelerate translation from discovery science into effective new interventions for anxiety, depression and psychosis, ready to be translated in clinical practice across the world.</p>
<p>Cirasola, Antonella; Midgley, Nick; Muran, J. Christopher; Eubanks, Catherine F.;</p>	<p>2023</p>	<p>Repairing alliance ruptures in psychodynamic psychotherapy with young people: The</p>	<p>Psychotherapy</p>		<p>No Paginatio Specified -No Paginatio</p>	<p>Alliance ruptures in youth psychotherapy can have a significant impact on treatment outcomes. However, there is currently limited guidance on how to effectively repair these ruptures with young people. This study aims to address this gap specifically in the context of psychodynamic psychotherapy with adolescents. The objectives of the study are (a) to understand the</p>

Hunter, Elaine Budreck; Fonagy, Peter		development of a rational–empirical model to support youth therapists				n Specified	therapeutic interventions and attitudes that either facilitate or hinder the resolution of alliance ruptures and (b) to develop a model for repairing these ruptures within this particular treatment approach. To accomplish this, a task analysis of a previously developed rational model of resolving alliance ruptures was conducted using 16 sessions from short-term psychodynamic psychotherapy with depressed adolescents. The analysis supported some stages of the hypothesized rational model while revealing the need for revisions. As a result, the study developed a rational–empirical model that includes flexible strategies that therapists can use to repair alliance ruptures. This model emphasizes the significance of a collaborative, open, and empathetic approach to resolving ruptures. In contrast, rigid, defensive, or invalidating therapist attitudes can hinder the resolution process. The evidence-based model developed from the study can provide valuable guidance to psychodynamic psychotherapists working with young people, offering insights on how to approach ruptures and employ effective strategies to promote their resolution. Claas, Petra	2022	"Wir haben uns spalten lassen". Unser Anteil an der Ausgrenzung der Personzentrierten Psychotherapie	Gesprächspsychotherapie und Personzentrierte Beratung	53	3	32–37	In einem persönlichen Appell wird der Frage nachgegangen, warum die humanistische Psychotherapie ihren Status als im Psychotherapeutengesetz anerkanntes Therapieverfahren verloren hat. Die Autorin spricht sich für einen Richtungswechsel in der Berufspolitik aus, der ihres Erachtens die einzige Chance bietet, die personzentrierte Psychotherapie zu erhalten. Sie skizziert aus ihrer Sicht schwerwiegende Fehlentwicklungen, die anerkannt werden müssten, um die

							personzentrierte Psychotherapie und andere humanistische Verfahren bewahren zu können.
Claas, Petra	2023	Trauma-Folge-Strungen nach früher und extremer Gewalt personzentriert behandeln	Gesprächspsychotherapie und Personzentrierte Beratung	54	3	24–29	In diesem Beitrag wird ein Personzentrierter Ansatz für die Behandlung von Menschen mit komplexen Posttraumatischen Belastungsstörungen und Dissoziativen Störungen beschrieben. Grundsätzlich für diesen Ansatz ist der konsequente Verzicht auf Haltungen, Konzepte und Interventionen aus anderen psychotherapeutischen Grundorientierungen. Angestrebt wird ein - in Bezug auf das zugrundeliegende Menschenbild und daraus abgeleiteten Grundhaltungen, Konzepten und Interventionen (Therapie-Wege) - kongruentes Vorgehen, das die Unverwechselbarkeit personzentrierter Psychotherapie spürbar und erkennbar werden lässt.
Clapton, Neil E.; Williams, Jonathan; Griffith, Gemma M.; Jones, Robert Sp	2018	'Finding the person you really are ... on the inside': Compassion focused therapy for adults with intellectual disabilities	Journal of intellectual disabilities : JOID	22	2	135–153	This study utilized a mixed methods approach to examine the feasibility and acceptability of group compassion focused therapy for adults with intellectual disabilities (CFT-ID). Six participants with mild ID participated in six sessions of group CFT, specifically adapted for adults with ID. Session-by-session feasibility and acceptability measures suggested that participants understood the group content and process and experienced group sessions and experiential practices as helpful and enjoyable. Thematic analysis of focus groups identified three themes relating to (1) direct experiences of the group, (2) initial difficulties in being self-compassionate and (3) positive emotional changes. Pre- and post-group outcome measures indicated significant reductions in both self-criticism and unfavourable social comparisons. Results suggest that CFT can be adapted for individuals with ID and provide preliminary evidence that people with ID and psychological difficulties may experience a number of benefits from this group intervention.

Clark-Sienkiewicz, Shannon M.; Caño, Annmarie; Zeman, Lori Lackman; Lumley, Mark A.; Gothe, Neha	2021	Development of a Multicomponent Intervention to Initiate Health Behavior Change in Primary Care: The Kickstart Health Program	Journal of clinical psychology in medical settings	28	4	694–705	<p>There is a growing movement to integrate behavioral health specialists into primary care settings in order to better manage patients' health behaviors. Group interventions in healthcare settings can provide services to multiple individuals simultaneously; however, the participants' experiences taking part in these activities and the logistics of integrating them into clinical settings are largely under-studied. This article describes the development and implementation of a novel group intervention for health behavior change, The Kickstart Health Program, which integrates components of cognitive, behavioral, acceptance, and experiential therapies. Participant feasibility, acceptability, experiences, and treatment course were assessed. Acceptability among a small sample of attendees was high, and initial data on behavior change suggest there were benefits to patients who attended the program. Increases in mindfulness practice and decreases in exercise barriers from baseline to 10-week follow-up were detected as were improvements in overall perceived health and well-being. Participants expressed that the program was acceptable and successful at helping them reach their individual health goals; however, enrollment barriers negatively impacted the feasibility of the program in regard to attendance. Modification to the enrollment process such as embedding referrals into the electronic medical record, encouraging spouse or family co-enrollment, and peer coaching may address these barriers. The Kickstart Health Program has the potential to improve health behaviors and paves the way for unique studies of dissemination and implementation of efficacious behavioral health interventions into real-world healthcare settings.</p>

<p>Clemens, Kristin K.; Getchell, Leah; Robinson, Tracy; Ryan, Bridget L.; O'Donnell, Jim; Reichert, Sonja M.</p>	<p>2019</p>	<p>Clinical care gaps and solutions in diabetes and advanced chronic kidney disease: a patient-oriented qualitative research study</p>	<p>CMAJ open</p>	<p>7</p>	<p>2</p>	<p>E258-E263</p>	<p>BACKGROUND: Patients with diabetes and advanced chronic kidney disease face a high health care burden. As part of a patient-oriented research initiative to identify ways to better support patients' diabetes care, we explored their health care experience and solutions for patient-centred diabetes care. METHODS: We engaged 2 patients with advanced kidney disease and diabetes to join our multidisciplinary team as full research partners. They were involved in our design and conduct of the study, the analysis of the results and knowledge translation. We conducted qualitative interviews (1:1 semistructured interviews and focus groups) with patients with a history of both diabetes (type 1 or 2) and advanced kidney disease including those using dialysis. We identified overarching themes using individual and team analysis and conducted interviews until data saturation was reached. RESULTS: Twelve participants were interviewed between October 2017 and February 2018. Six people were interviewed in 2 separate focus groups (consisting of 4 and 2 participants) and 6 participated in 1:1 interviews with our team. Participants described being burdened by medical appointments, strict conflicting diets, costly diabetes therapies and fragmented, siloed health care. They indicated that self-management support, education and coordinated diabetes care might better support their diabetes care. INTERPRETATION: Patients with complex medical comorbidities face many challenges traversing a health care system organized around single diseases. Researchers and policy-makers should study and develop patient-centred diabetes care strategies to better support these high-risk patients.</p>

<p>Cloitre, Marylene; Morabito, Danielle; Macia, Kathryn; Speicher, Sarah; Froelich, Jessilyn; Webster, Katelyn; Prins, Annabel; Villasenor, Diana; Bauer, Asha; Jackson, Christie; Fabricant, Laura; Wiltsey-Stirman, Shannon; Morland, Leslie</p>	<p>2024</p>	<p>A home-based telehealth randomized controlled trial of skills training in affective and interpersonal regulation versus present-centered therapy for women veterans who have experienced military sexual trauma</p>	<p>Journal of consulting and clinical psychology</p>			<p>No Paginat ion Specified -No Paginat ion Specified</p>	<p>Objective: This randomized trial tested the effectiveness of Skills Training in Affective and Interpersonal Regulation (STAIR) compared to present-centered therapy (PCT) delivered virtually to women veterans who had experienced military sexual trauma (MST) and screened positive for posttraumatic stress disorder (PTSD). Method: One hundred sixty-one eligible women veterans were randomized into the study. The primary outcome was clinician-assessed PTSD severity (Clinician-Administered PTSD Scale–5), while secondary outcomes included social support and several other symptom measures at posttreatment through 2- and 4-month follow-up. Results: PTSD severity decreased in both conditions by posttreatment but significantly more ($p = .028$, $d = 0.39$) in STAIR ($d = 1.12 [0.87, 1.37]$) than PCT ($d = .78 [0.54, 1.02]$). STAIR was also superior in improving social support and emotion regulation and reducing depression and negative cognitions. Improvement in psychosocial functioning was moderate and did not differ between conditions. All changes were maintained through 2- and 4-month follow-ups. Dropout rates were low and did not differ (19.0% and 12.2%, respectively). Conclusion: STAIR provided superior outcomes compared to PCT regarding PTSD, social support, and multiple types of mental health problems among women veterans with MST. The application of STAIR to other populations with social support and related concerns warrants investigation. The substantial effect sizes for PTSD symptoms in both treatments suggest that they are practical alternatives for individuals who do not wish to participate in trauma-focused therapy and may increase engagement in mental health services. Cloutier, Briana; Francoeur, Audrey; Samson, Crystal; Ghostine, Alexandra; Lecomte, Tania	2021	Romantic relationships, sexuality, and psychotic disorders: A systematic review of recent findings	Psychiatric Rehabilitation Journal	44	1	22–42	<p>For individuals with a psychotic disorder, dating can present several challenges and lead many to be excluded from intimate relationships. These difficulties may stem from a number of factors, including impairments in social and sexual functioning. Although scientific interest in this topic is mounting, the last quantitative review of the literature dates back to 2003. Objectives: The aim of this systematic review was to collect, evaluate, and synthesize quantitative data from studies published in the last 15 years on romantic relationships and sexuality in the context of a psychotic disorder. Methods: Articles were retrieved from PsycINFO, PubMed, Web of Science, and ProQuest databases and were retained if they met the following inclusion criteria: (a) original research or meta-analysis, (b) complete or partial sample with a psychotic disorder diagnosis, (c) provision of quantitative data specific to the population of interest, and (d) studies focusing on romantic relationship and/or sexuality variables as correlates, predictors, mediators, or outcomes. Study quality was evaluated using PRISMA criteria. Results: 43 studies were identified, 24 of which were categorized as obstacle-related (e.g., focusing on negative aspects of intimacy, such as risky behaviors) and 19 of which were deemed neutral or recovery-oriented (e.g., focusing on positive aspects of intimacy, such as marital functioning). Conclusions and Implications for Practice: Results highlight a need for greater communication and assistance in the areas of intimacy and sexuality for persons with psychotic disorders. Better access to resources such as dating skills and couples therapy programs as well as more consumer-oriented research is needed. (PsycInfo Database Record (c) 2021 APA, all rights reserved)</p>

Coggins, Kim; Carnes-Holt, Kara	2021	The efficacy of child–teacher relationship training as an early childhood mental health intervention in Head Start programs	International Journal of Play Therapy	30	2		This randomized repeated-measured active control group study examined the efficacy of child–teacher relationship training (CTRT) as a mental health intervention in rural Head Start programs with at-risk children. Experimental group child participants demonstrated statistically significant decreases in total problem behaviors when compared with active control group children. All child participants exhibited improvements in targeted behaviors with small-to-moderate treatment effects. The findings indicate that CTRT positively influences children’s problem behaviors with implications for rural mental health interventions. Cohen-Chazani, Yael; Lysaker, Paul H.; Roe, David; Hasson-Ohayon, Ilanit	2021	Metacognitive reflection and insight therapy in an inpatient setting: Transforming messianism to a coherent mission	Journal of clinical psychology	77	8	1836–1850	Metacognitive reflection and insight therapy (MERIT) is an integrative form of psychotherapy which seeks to help adults with serious mental illness make sense of the psychosocial challenges and possibilities they face and decide how to respond to them and direct their own recovery. In this article, we present an adaptation of MERIT to the context of an inpatient ward with an accompanied case illustration. Specifically, we describe how this approach is supported by a broad intersubjective framework, followed by a presentation of processes and contents of the treatment. Special attention is given to the concurrent improvements in reflective abilities and overall well-being of the patient. The unique role that psychotherapy in general, and approaches that emphasize reflective processes in particular, play during acute crises in an inpatient setting is discussed.
Colbert, Susannah	2023	The Impact On Eye Movement And Desensitization	Journal of trauma & dissociation : the official			1–14	In a drug-facilitated sexual assault (DFSA), the person's level of intoxication may result in incomplete memory. This paper describes eye movement and desensitization reprocessing (EMDR) with client-centered adaptations to

		Reprocessing Of Incomplete Memory In A Drug-Facilitated Rape: A Single Case Study	journal of the International Society for the Study of Dissociation (ISSD)				address an incomplete trauma memory in a 26-year-old woman. The client was experiencing PTSD, characterized by nightmares and derealization. Therapy followed standard EMDR procedures with three minor modifications to help the client maintain current awareness. Although the memory remained incomplete, the client-centered adaptations promoted working through of the clients' trauma responses (e.g. disorientation, physical sensations) and a sense of competence and self-confidence were restored. At the end of reprocessing, and at follow-up, the client was no longer experiencing nightmares or derealization and her wellbeing had improved.
Cole, Brian P.; Petronzi, Gregory J.; Singley, Daniel B.; Baglieri, Michael	2019	Predictors of men's psychotherapy preferences	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	1	45-56	
Coleman, Jeremy J.; Drinane, Joanna M.; Owen, Jesse; Sinha, Sree; Porter, Emma Freetly; Agorsor, Courtney; DeBlaere, Cirteen; Davis, Don E.	2023	Psychotherapy with clients who are incarcerated: Therapists' multicultural orientation, alliance, and outcomes	Professional Psychology: Research and Practice			No Paginat ion Specified -No Paginat ion Specified	Jails and prisons commonly offer mental health treatments as many people experiencing incarceration suffer from significant psychological distress and substance use problems. One modality through which individuals who are incarcerated receive care is psychotherapy; however, process and outcome data in this population are limited. More specifically, little is known about how culture and identity impact the development therapeutic relationship in this context. The multicultural orientation framework, which includes three pillars (cultural humility, cultural opportunities, and cultural comfort), aims to operationalize cultural processes in psychotherapy (J. Owen, 2013). We examined the relationship between therapy outcomes

							and client ratings of their therapist’s cultural humility (positive and negative), cultural opportunities, and the working alliance in two jails. Ninety-four clients engaging in routine psychotherapy rated their experience of the therapy process during their third session. Interestingly, we did not find significant associations between therapy outcomes (i.e., psychological distress and relational distress) and negative cultural humility or cultural opportunities. We did find a significant positive association between the working alliance and therapy outcomes. Notably, therapy outcomes were negatively associated with positive cultural humility, suggesting that clients who rated their therapist higher on positive cultural humility had worse therapy outcomes. Therefore, there may be important setting specific factors that contribute to the importance of orienting to culture in psychotherapy. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Collardeau, Fanie; Bin Aftab, Muhammad Usama; Jibeen, Tahira; Woodin, Erica	2021	Pakistani immigrants' nuanced beliefs about shame and its regulation	International Perspectives in Psychology: Research, Practice, Consultation	10	1	25–38	The present study explored beliefs about shame and coping strategies of Pakistani immigrants to Canada, without imposing Western definitions or theories. Semistructured interviews were conducted with 18 adult Pakistani immigrants to Canada who immigrated within the last 8 years. Grounded theory was used to uncover and illuminate how shame could act as a signal for wrongdoing or emerge as a result of social control and social hierarchies, while in both instances being shaped by and informing complex relational and social contexts. Participants accessed a wide range of positive and negative coping behaviors and prioritized positive coping strategies which included close others and focused on self-improvement. The findings highlight the need for researchers to expand current definitions of shame to

							render them more inclusive of non-Western worldviews and to honor the diversity in metacognitions or beliefs about shame present in different cultural groups. Future research may also benefit from exploring how shame may be felt as a response to power differentials, and how this may impact individuals' experiences of immigration. It is important for practitioners working with Pakistani immigrants to Canada to honor clients' nuanced and complex cultural and religious knowledge about shame, as Pakistani immigrants' beliefs about shame and their proactive stance toward the regulation of this emotion are likely to be protective. We also encourage therapists to be open to discussing sources of shame (e.g., personal vs. imposed by others) and systemic, structural inequalities which may be important in explaining individuals' emotional experience. Colvonen, Peter J.; Drummond, Sean P. A.; Angkaw, Abigail C.; Norman, Sonya B.	2019	Piloting cognitive-behavioral therapy for insomnia integrated with prolonged exposure	Psychological Trauma: Theory, Research, Practice, and Policy	11	1	107-113	Objective: Approximately 35-61% of individuals with posttraumatic stress disorder (PTSD) report insomnia. Further, upward of 70% report clinically significant insomnia following PTSD treatment. There are converging lines of evidence suggesting that insomnia not only independently affects daytime functioning and worsens PTSD symptoms but also may compromise response to PTSD treatment, such as prolonged exposure (PE). Taken together, integrated insomnia and PTSD treatment may increase client-centered care and treatment outcomes. Method: This article reviews the theory and evidence for treating sleep prior to PTSD treatment, describes the key elements of integrated cognitive-behavioral treatment for insomnia (CBT-I) and PE (2NITE protocol), and presents pilot data from a sample of 12 treatment-seeking veterans with PTSD and insomnia who completed the 2NITE

							<p>protocol. Sleep data were collected with sleep diaries and actigraphy watches. Results: The Client Satisfaction Questionnaire indicated high satisfaction with the 2NITE protocol (mean score 29.66 out of 32 points). On average, there were statistical and clinically significant changes in all measures, including a 20.17-point decrease in the PTSD Checklist DSM-5, a 11.75-point decrease in the insomnia severity index, an 18.58-point increase in the World Health Organization Quality of Life index, a 11% increase in sleep efficiency, and a 51-min increase in total sleep time from the actigraphy data. Conclusions: Among individuals with insomnia and PTSD, integrating CBT-I and PE with the 2NITE protocol represents a logical, innovative, and empirically informed method for augmenting existing treatments and optimizing outcomes that justifies further investigation. Cone, Deborah Hill	2020	Double-Think, Double-Binds and the Secret History of Borderline Personality Disorder	Brit J Psychotherapy (British Journal of Psychotherapy)	36	2	294-302	<p>The clinical diagnosis of borderline personality disorder carries a uniquely pungent stigma. The literature repeatedly refers to these patients as manipulative, malignant and treatment resistant. In this paper, it is argued that when viewed within a broader matrix, the person with borderline organization exhibits unstable emotions and behaviour not because they are ?difficult? but because they lack the option of more socially sanctioned defences. This personality organization has developed because they have been trapped in some kind of irreconcilable circumstance (a double-bind) and yet also required to deny the truth of this (double-think). The author explores how this mechanism may be present in less obviously dysfunctional manifestations for many people, including herself, a 50-year-old psychotherapy student. This paper argues the person with borderline</p>

							organization is grappling with the paradoxical need for both merger and separation, but this may be better understood as not just trying to make meaning for themselves as an individual, but as bearing the psychic burden for generations who have gone before them, such as the indigenous Maori people of New Zealand (Aotearoa), who experienced the trauma of colonization.
Connery, Amy; Cavanna, Andrea E.; Coleman, Ross	2023	Can Stoicism inspire stuttering intervention? The clinical usefulness of an ancient philosophy	International journal of language & communication disorders	58	3	977–987	<p>BACKGROUND A range of psychotherapies are effective in managing an individual's personal reactions to stuttering and reducing the impact stuttering has on their lives. Many of these therapies, such as cognitive behavioural therapy, have their origins in Stoicism, an ancient Greek philosophy founded in 301 bce. Stoicism remains a relatively unexplored topic in the psychotherapy and speech and language therapy literatures.</p> <p>AIMS This paper aims to highlight the potential benefits of integrating Stoic principles and techniques into stuttering intervention.</p> <p>METHODS This aim is achieved through a discussion on Stoic philosophy and the range of techniques that have informed modern evidence-based psychotherapies that are effective with the stuttering population.</p> <p>MAIN CONTRIBUTION This paper initiates an important conversation on the usefulness of Stoicism to the field of stuttering. Key recommendations are provided for the integration of Stoic philosophy into future clinical and research practice related to stuttering.</p> <p>CONCLUSIONS Stoicism offers philosophical guidance for the art of</p>

						<p>living, but also provides a range of strategies and practical techniques that have potential to expand the clinical toolkit of modern psychotherapy and speech and language therapy. Scientific validation of the clinical application of Stoicism is recommended to exploit its effectiveness with the stuttering population.</p> <p>WHAT THIS PAPER ADDS</p> <p>What is already known on the subject Stoicism is an ancient philosophy that has informed modern-day psychotherapies including cognitive behavioural therapy (CBT) and acceptance and commitment therapy (ACT). Such therapies are recommended for use with individuals who stutter to target their personal reactions to stuttering and reduce any adverse impacts on their lives. What this paper adds to existing knowledge This paper discusses the principles and techniques of Stoicism with reference to how they align with modern psychotherapeutic approaches and speech and language therapy interventions used with individuals who stutter. Clinical implications and directions for future research are also presented. What are the potential or actual clinical implications of this work? Speech and language therapists (SLTs) are recommended to continue their use of psychotherapies such as CBT and ACT with individuals who stutter. In addition, SLTs are advised to explore Stoicism and its range of techniques to better understand the philosophical underpinnings of evidence-based psychotherapies and to expand their clinical toolkit.</p>
Connolly Gibbons, Mary Beth; Duong, Lang; Zoupou, Eirini; Kashden,	2023	Randomized controlled trial evaluating feedback to community-	Journal of consulting and clinical psychology	91	6	<p>Objective: Patient trust/respect toward their therapists may be an important component of patient–therapist relationships. This randomized controlled trial evaluated the impact of providing weekly feedback to therapists regarding patient ratings of trust/respect toward their</p>

Jody; Fisher, Jena; Crits-Christoph, Paul		based therapists based on patient reports of trust and respect					<p>therapist. Method: Adult patients seeking mental health treatment at four community clinics (two community mental health centers and two community-based intensive treatment programs) were randomized to either having their primary therapist receive weekly symptom feedback-only or symptoms plus trust/respect feedback. Data were collected both prior to and during COVID-19. The primary outcome measure was a measure of functioning obtained weekly at baseline and the subsequent 11 weeks, with the primary analysis focusing on patients who received any treatment. Secondary outcomes included measures of symptoms and trust/respect. Results: Among 233 consented patients, 185 had a postbaseline assessment and were analyzed for the primary and secondary outcomes (median age of 30 years; 5.4% Asian, 12.4% Hispanic, 17.8% Black, 67.0% White, 4.3% more than 1 race, and 5.4% unknown; 64.4% female). On the Patient-Reported Outcomes Measurement Information System Social Roles and Activities scale (primary outcome), the trust/respect plus symptom feedback group had significantly greater improvements over time than the symptom alone feedback group ($p = .0006$, effect size $d = .22$). Secondary outcome measures of symptoms and trust/respect also showed statistically significant greater improvement for the trust/respect feedback group. Conclusions: In this trial, trust/respect feedback to therapists was associated with significantly greater improvements in treatment outcomes. Evaluation of the mechanisms of such improvements is needed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Conradi, Henk Jan;	2018	Effectiveness of the 'Hold me	Family process	57	3	613–628	While evidence-based couple therapies are available, only a minority of troubled couples seek help and they

Dingemanse, Pieter; Noordhof, Arjen; Finkenauer, Catrin; Kamphuis, Jan H.		Tight' Relationship Enhancement Program in a Self-referred and a Clinician-referred Sample: An Emotionally Focused Couples Therapy-Based Approach					often do this too late. To reach more couples earlier, the couple relationship education (CRE) group program "Hold me Tight" (HmT) based on Emotionally Focused Couples Therapy (EFCT) was developed. This study is the first to examine the effectiveness of HmT. Using a three-wave (waiting period, treatment, and follow-up) within-subject design, HmT was delivered to 79 self-referred couples and 50 clinician-referred couples. We applied a comprehensive outcome measure battery. Our main findings were that (1) self-referred couples significantly improved during HmT on all measures, that is relationship satisfaction, security of partner-bond, forgiveness, daily coordination, maintenance behavior, and psychological complaints, with a moderate-to-large mean effect size ($d=.63$), which was maintained ($d=.57$) during the 3.5month follow-up; (2) in clinician-referred couples, who were vulnerable in terms of insecure attachment status and psychopathology, the improvement during HmT was moderate ($d=.42$), but this was reduced during the 3.5-month follow-up to a small effect ($d=.22$); (3) emotional functioning (typical HmT target) as well as behavioral functioning (typical Behavioral Couples Therapy-based CRE target) improved during HmT; and (4) individual psychological complaints, although not specifically targeted, were reduced during HmT. These findings suggest that HmT is a promising intervention for enhancement of relationship functioning. Clinical implications are discussed. 2017 Family Process Institute.
Conroy, Eilis; Vélez-Gómez, Beatriz; O'Brien, David; Heverin,	2023	IMPACT-ALS: summary of results from a European	Amyotrophic lateral sclerosis &			1-10	OBJECTIVE: The IMPACT-ALS survey collected the experiences of people living with ALS (plwALS) across nine European countries. We aimed to better understand the functional burden of ALS to ensure the experiences of

Mark; Hardiman, Orla; Mcdermott, Christopher; Galvin, Miriam		survey of people living with ALS	frontotemporal degeneration				plwALS inform the development of person-centered therapies. METHODS: The content was informed by the US IMPACT-ALS survey, with adjustments relevant to the European population. Questionnaires consisted of four modules, each of which was pilot tested in advance of distribution. Data were captured using the Qualtrics software and were analyzed in SPSS. RESULTS: 857 respondents completed the survey, with a participation rate ranging from 0.2% to 6.3% across the nine participating countries. The majority were male and aged 55-74 years old. In the previous 2 weeks, symptoms experienced included weakness (81%), fatigue (61%), speech impairment (38%), pain (27%), and depression and other mood changes (23%). Eighty-two percent of respondents reported fears, of which the most common were leaving family too soon (68%) and death from respiratory failure (50%). Lifestyle changes since diagnosis were reported by 89% of respondents, with less time spent doing most daily activities but more time on the internet (81%), reading (56%) and communicating with family and friends (55%). Stopping progression of ALS was the most desired impact for a new therapy for 68% respondents. CONCLUSIONS: The European IMPACT-ALS survey has generated insights into the complex experiences of plwALS. The data provide unique patient perspectives on common symptoms, fears, functional limitations, lifestyle changes, and wishes for future therapies that will enhance patient-centric care in ALS.

Constantino, Michael J.; Laws, Holly B.; Coyne, Alice E.; Greenberg, Roger P.; Klein, Daniel N.; Manber, Rachel; Rothbaum, Barbara O.; Arnow, Bruce A.		Change in patients' interpersonal impacts as a mediator of the alliance-outcome association in treatment for chronic depression	Journal of consulting and clinical psychology	84	12	Objective: Theories posit that chronically depressed individuals have hostile and submissive interpersonal styles that undermine their interpersonal effectiveness and contribute to the cause and maintenance of their depression. Recent findings support this theory and demonstrate that chronically depressed patients' interpersonal impacts on their therapist become more adaptive (i.e., less hostile and submissive, and more friendly and assertive) during a targeted chronic depression treatment: cognitive-behavioral analysis system of psychotherapy (CBASP). In this study, the authors examined whether such changes in interpersonal impacts (as rated by clinicians' experiences of interacting with their patients) mediated the association between early patient-rated alliance quality and final session depression. Method: Data derived from a large trial for chronic depression that compared the efficacy of CBASP, nefazodone, and their combination. The current subsample (N = 220) included patients in the CBASP and combined conditions who completed at least 1 depression assessment and the alliance measure, and whose therapists completed at least 1 interpersonal impacts assessment. Mediation models were fit using a bootstrapping procedure for assessing indirect effects. Results: As hypothesized, results supported a mediating effect; higher early alliance predicted decreases in patient hostile-submissiveness during therapy, which in turn related to lower final session depression (indirect effect $B = -.02$, 95% confidence interval: $-.07, -.001$). This indirect effect accounted for 13% of the total effect of alliance on depression. There was no moderating effect

							of treatment condition on the indirect effect. Conclusions: Results further support CBASP change theory and suggest a candidate mechanism of the alliance's effect on outcome. (PsycINFO Database Record (c) 2016 APA, all rights reserved)
Constantino, Michael J.; Morrison, Nicholas R.; Coyne, Alice E.; Goodwin, Brien J.; Santorelli, Gennarina D.; Angus, Lynne	2017	Patients' Perceptions of Corrective Experiences in Naturalistically Delivered Psychotherapy	Journal of clinical psychology	73	2	139-152	Corrective experiences (CEs), which suggest transformative experience(s) for the psychotherapy patient, have a rich theoretical history; yet there is little empirical information on patients' own perceptions of what gets "corrected" from therapy, and what is "corrective" (i.e., the mechanisms driving the CE). To address this gap, we investigated 14 patients' posttreatment accounts of both CE elements in the context of naturalistically delivered individual psychotherapy, using a consensual qualitative research methodology. Extending prior research focused on patients' accounts of CEs while still engaged in treatment (Heatherington et al., 2012), the present results revealed that patients retrospectively identified an array of categories that were deemed corrected, such as positive changes in cognitions, interpersonal problems, self-concepts, symptoms, and behaviors. Patients also identified CEs that may have led to those shifts/transformations, including their therapist's actions (especially giving feedback), their own agentic actions (especially engaging in the therapeutic process), and the patient-therapist collaborative and engaged relationship. Clinical practice implications are discussed.
Constantinou, Constantina; Kolokotroni, Ourania; Mosquera,	2020	Developing a holistic contingency plan: Challenges and	Cancer medicine	9	17	6082-6092	During the first quarter of 2020 the world is experiencing a pandemic of Severe Acute Respiratory Syndrome-Coronavirus-2 (SARS-CoV-2), a novel beta coronavirus that is responsible for the 2019 novel coronavirus disease (COVID-19). The COVID-19 pandemic revealed that

<p>Maria-Cecilia; Heraclides, Alexandros; Demetriou, Christiana; Karayiannis, Peter; Quattrocchi, Annalisa; Charalambous, Andreas</p>		<p>dilemmas for cancer patients during the COVID-19</p>					<p>healthcare systems around the world were not prepared to deal with either the direct effects of the pandemic or with the indirect effects that are imposed on the health of patients with chronic disorders such as cancer patients. Some challenges and dilemmas currently faced during the pandemic include the management of cancer patients during the treatment and follow-up phases, the assessment of the safety of treatments currently used for the management of SARS-CoV-2 for use in cancer patients, the development of psychoeducation and emotional support for cancer patients and the safe conduct of clinical trials involving participation of cancer patients. Evidence from the literature supports the need for the urgent development of a holistic contingency plan which will include clear guidelines for the protection and comprehensive care of cancer patients. The implementation of such a plan is expected to have many beneficial effects by mainly minimizing the increased morbidity and mortality of cancer patients that could result as an adverse consequence of the COVID-19 or future pandemics.</p>
<p>Contractor, Ateka A.; Jin, Ling; Weiss, Nicole H.</p>	<p>2023</p>	<p>Open label pilot study on posttrauma health impacts of the Processing of Positive Memories Technique (PPMT)</p>	<p>Journal of Psychotherapy Integration</p>	<p>33</p>	<p>2</p>	<p>213–234</p>	<p>Processing of Positive Memories Technique (PPMT) was proposed as a novel intervention for posttraumatic stress disorder (PTSD). PPMT comprises of 5 sessions focused on identifying and processing positive memories. As an open label pilot study, we explored PPMT's effects on PTSD severity, depression severity, affect and cognitive processes, and therapeutic alliance. A sample of 12 trauma-exposed participants seeking services at a University Psychology Clinic participated in 5 PPMT sessions (Mage = 29.25 years; 58.30% women). We used the reliable change indices and clinically significant change score approach. The following number of</p>

							<p>participants showed statistically reliable changes: 9 participants for PTSD severity (8 recovered/improved); 6 participants for depression severity (5 improved); 5 participants for positive affect levels (2 recovered/improved); 9 participants for negative affect levels (8 recovered); 9 participants for posttrauma cognitions (7 recovered/improved); 5 participants for positive emotion dysregulation (4 recovered); 11 participants for number of retrieved positive memories (3 recovered); and 5 participants for therapeutic alliance (4 recovered). PPMT may impact certain posttrauma targets more effectively (PTSD, depression, negative affect, posttrauma cognitions). PPMT may be more helpful in improving regulation rather than levels of positive affect. PPMT, if supported in further investigations, may add to the clinician's tool-box of PTSD interventions. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Convoy, Sean P.; Westphal, Richard J.; Convoy, Dana W.	2019	Concordant Actions in Suicide Assessment Model	The Nursing clinics of North America	54	4	533-539	<p>This article offers an alternative conceptualization from which a health care provider can consider and respond to client-based suicidal ideation and behavior. Pragmatically explored through the prism of locus of control, Rogerian psychotherapy principles, Peplau's theory of interpersonal relations, and the work of Kay Redfield Jamison, the Concordant Actions in Suicide Assessment (CASA) model frames clinical decision making along a continuum defined by concordant and state-based action. Therein, cognitive reframes are offered to illustrate how to apply the CASA model in clinical practice.</p>
Cook, Tina; Noone, Steven; Thomson, Megan	2019	Mindfulness-based practices with family carers of adults with learning	Health expectations : an international journal of public participation in	22	4	802-812	<p>BACKGROUND: Family carers of adults with learning disability and behaviours that challenge lead complex and stressful lives. Their caring role can leave them isolated and unsupported. In the UK, effective services designed to build resilience for people in long-term caring</p>

		disability and behaviour that challenges in the UK: Participatory health research	health care and health policy				<p>roles are lacking. There are none (to our knowledge) designed using a participatory health research (PHR) approach with family carers and professionals.</p> <p>OBJECTIVE: With positive behaviour support (PBS) and mindfulness and acceptance and commitment therapy (ACT) as key elements, a PHR approach was used to understand the basis for a successful course that supported the capabilities and resilience of family members in long-term caring roles. DESIGN: The research was guided by the principles of PHR with participation as the defining principle throughout. Central to the research were reflexive conversations (communicative spaces) where diverse knowledges were shared and critiqued. FINDINGS: Mindfulness/ACT can change long-standing response behaviours and build personal resilience and improve mental health. Elements enabling positive change included a facilitation approach for collaborative reflexivity and the complementary, interactive approach to collaborative enquiry for learning and decision making afforded by PHR. DISCUSSION: The use of PHR accessed knowledges that would have been lost to more traditional, professional-expert driven processes and facilitated change in constructs for action for both professionals and family carers. Findings challenge service providers to consider how experiential knowledge has agency in professional practice and service design. Reflection on the PHR process across the FaBPos project led to a re-consideration of quality issues in relation to PHR and participation.</p>
Cooper, Denise C.; Bates, Mark J.	2019	Military Health Provider Training and Evaluation of a Problem-	Military medicine	184	5-6	e303-e311	<p>INTRODUCTION: Department of Defense (DoD) has identified problem-solving training (PST) as a promising prevention/early intervention for mental health disorders. PST is a four-session group intervention that emphasizes</p>

		Solving Intervention to Reduce Distress and Enhance Readiness Among Service Members					building problem-solving and coping skills to mitigate emotional dysregulation and the adverse effects of stressful events. It was adapted from problem-solving therapy, which is an evidence-based, cognitive-behavioral approach that has shown effectiveness with treating depression and managing suicide risk. The current evaluation examined a pilot program that: (1) trained DoD providers in the delivery of PST, (2) conducted PST intervention groups with active duty personnel, and (3) developed PST master trainers to train other providers. MATERIALS AND METHODS: Clinical (e.g., psychologists) and non-clinical (e.g., chaplains) providers attended a 2.5-day workshop of didactic coursework and experiential training on conducting PST, with a subset of providers selected to attend an additional workshop to become master trainers in PST. Providers (n = 82) who attended a PST Facilitator Workshop completed pre- and post-workshop assessments of self-efficacy in PST skills. Eight providers evaluated a Master Trainer Workshop. After completing workshop training, providers conducted PST intervention groups with service members (n = 435), who were experiencing distress, with or without a mental health diagnosis, and whose needs were appropriate for a prevention/resiliency-based skills group. Service members completed the following pre- and post-PST group outcome measures: (a) Outcome Questionnaire-30 (OQ-30) and Patient Health Questionnaire-9 (PHQ-9) as measures of distress; and (b) Brief Resilience Scale (BRS) to assess resilience, which contributes to readiness. They also completed the Social Problem Solving Inventory-Revised: Short Form (SPSI-R:S), as a process measure for the intervention. The SPSI-R:S, which assesses how individuals cope when faced with problems, includes the
--	--	---	--	--	--	--	---

							<p>following subscales: (1) positive problem orientation, (2) negative problem orientation, (3) rational problem-solving, (4) impulsivity/carelessness style, and (5) avoidance style. Service members also completed a post-group evaluation of PST. Data were analyzed with descriptive statistics, paired sample t-tests, and correlational analyses. RESULTS: Providers showed pre- to post-facilitator workshop increases in self-efficacy of PST skills (all $p < 0.001$) and those selected as master trainers evaluated their workshop training favorably, particularly the role-playing exercises. Analyses of pre- vs. post-PST group intervention measures among service members indicated that OQ-30 and PHQ-9 scores declined, while BRS and SPSI-R:S total scores increased (all $p < 0.001$). In addition, correlational analyses of change scores showed that the SPSI-R:S subscales negative problem orientation and avoidance style were negatively correlated with BRS and positively correlated with OQ-30 and PHQ-9 (all $p < 0.001$). Service members gave positive post-group evaluations of PST effectiveness and program materials. CONCLUSION: DoD providers reported increased self-efficacy in skills required for the delivery of a four-session PST group intervention after participating in a pilot program of training workshops. The pilot of the PST group intervention showed an association with improvements on service members' self-reported measures related to distress, readiness, and coping. In addition, changes in problem-solving measures were associated with changes in outcome measures. Follow-on research is needed to further investigate if PST is effective in preventing more severe forms of distress.</p>
Cooper, Mick; Norcross, John	2019	Psychotherapy preferences of	Psychotherapy	56	2	205–216	What do patients prefer in their psychotherapy? Do laypersons and mental health professionals (as patients)

C.; Raymond-Barker, Brett; Hogan, Thomas P.		laypersons and mental health professionals: Whose therapy is it?					want the same, or different, things? The authors systematically examined patients' psychotherapy preferences and quantitatively compared two samples of laypersons (N = 228, 1,305) with one sample of mental health professionals (N = 615) on the four dimensions of the Cooper–Norcross Inventory of Preferences: Therapist Directiveness Versus Client Directiveness, Emotional Intensity Versus Emotional Reserve, Past Orientation Versus Present Orientation, and Warm Support Versus Focused Challenge. On average, laypersons wanted therapist directiveness and emotional intensity. Robust differences were found between laypersons' and professionals' preferences on these two dimensions: Mental health professionals wanted less therapist directiveness than did laypersons ($g_s = 0.92$ and 1.43 between groups) and more emotional intensity ($g_s = 0.49$ and 1.33). Women also wanted more warm support than men ($g_s = 0.40$ and 0.57). These findings suggest that psychotherapists should be mindful of their own treatment preferences and ensure that these are not inappropriately generalized to patients. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Cooper, Mick; Xu, Dan	2023	Goals Form: Reliability, validity, and clinical utility of an idiographic goal-focused measure for routine outcome monitoring in psychotherapy	Journal of clinical psychology	79	3	641–666	<p>OBJECTIVE This study aimed to assess the reliability, validity, and clinical utility of an idiographic, goal-focused patient-reported outcome measure: The Goals Form.</p> <p>METHODS Data were analyzed from 88 participants, across three samples, who had participated in collaborative-integrative psychotherapy at university-based clinics in the UK. The samples were approximately 70% female with mean age of 30 years old.</p> <p>RESULTS</p>

							<p>The psychometric properties of the Goals Form were generally good. Noncompletion of individual items was low, temporal stability tended to be at target levels, and mean change scores showed moderate to good convergent validity against measures of psychological distress. The measure appeared sensitive to change in psychotherapy and was experienced by most patients as helpful.</p> <p>CONCLUSIONS</p> <p>The Goals Form shows acceptable psychometric and clinical properties for routine outcome monitoring in psychotherapy.</p>
Corbin, J. Hope; Sanmartino, Mariana; Hennessy, Emily Alden; Urke, Helga Bjørnøy	2021	Arts and Health Promotion: Tools and Bridges for Practice, Research, and Social Transformation					
Cordeiro, Kristina; Wyers, Cassandra; Oliver, Meghan; Foroughe, Mirisse; Muller, Robert T.	2022	Caregiver maltreatment history and treatment response following an intensive Emotion Focused Family Therapy workshop	Clinical psychology & psychotherapy	29	5	1728–1741	<p>This single-arm, repeated measures study investigated the impact caregiver trauma history may have on treatment response following an intensive, 2-day Emotion Focused Family Therapy (EFFT) caregiver workshop. Caregivers (n = 243) completed questionnaires regarding their child's emotion regulation and clinical symptoms, as well as their own childhood trauma history (i.e., exposure to various forms of child maltreatment), caregiver self-efficacy and caregiver blocks (e.g., fears) to support their child's treatment and recovery. Questionnaires were administered prior to and immediately following the workshop and again 4, 8 and 12 months later. At baseline, caregivers who reported experiences of childhood</p>

						<p>maltreatment demonstrated more blocks compared with caregivers who did not ($B = 6.35$, $SE = 2.62$, $p < 0.05$). Results indicated that caregivers with and without maltreatment histories reported similar, significant gains in their child's total difficulties ($B = 0.64$, $SE = 0.41$, $p = 0.12$) and emotional negativity and lability ($B = 0.51$, $SE = 0.48$, $p = 0.29$) at 12-month post-workshop. Caregivers with maltreatment histories reported greater improvements in caregiver blocks ($B = 5.15$, $SE = 1.34$, $p < 0.001$) and child emotion regulation ($B = 0.90$, $SE = 0.18$, $p < 0.001$) than caregivers without maltreatment histories. They also report less, but still significant, improvement in parental self-efficacy ($B = -0.68$, $SE = 0.26$, $p < 0.01$) when compared with caregivers without maltreatment histories. Findings suggest that EFFT workshops may be an acceptable and effective trans-diagnostic intervention for families presenting with complex histories, including caregiver exposure to childhood maltreatment.</p>
<p>Cornelis, Shana; Desmet, Mattias; Meganck, Reitske; Cauwe, Joachim; Inslegers, Ruth; Willemsen, Jochem; van Nieuwenhove, Kimberly; Vanheule, Stijn; Feyaerts, Jasper;</p>		<p>Interactions between obsessional symptoms and interpersonal dynamics: An empirical single case study</p>		<p>34</p>	<p>4</p>	<p>Both classical and contemporary psychoanalytic theories stress the importance of interpersonal dynamics in treating neurotic symptoms. Associations between the symptomatic and interpersonal level were formally represented in the symptom specificity hypothesis (Blatt, 1974, 2004), which linked obsessional symptoms to an autonomous interpersonal stance. Findings from cross-sectional group studies on symptom specificity, however, do not converge, possibly indicating that the complexity of associations is underestimated. This article presents a theory-building case study specifically aiming at refinement of the classical symptom specificity hypothesis by quantitatively and qualitatively describing the longitudinal clinical interplay between obsessional</p>

Vandenbergen, Jan						symptoms and interpersonal dynamics throughout a psychodynamic psychotherapy. Interpersonal functioning was assessed by means of the core conflictual relationship theme method (Luborsky & Crits-Cristoph, 1998). Findings affirm a close association between symptoms and interpersonal dynamics. However, obsessional symptoms proved to be determined by profound ambivalences—manifesting both within and between relationships—between dependent and autonomous interpersonal behavior. Psychodynamic interventions focusing on interpersonal conflicts were associated with symptomatic alterations. Conceptual and methodological considerations, limitations and future research indications are discussed. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Cornish, Marilyn A.; Hanks, Madison A.; Gubash Black, Sharon M.	2020	Self-forgiving processes in therapy for romantic relationship infidelity: An evidence-based case study	Psychotherapy	57	3	Self-forgiveness is related to positive connections with self and others and may be particularly important for clients who have hurt others. Relational hurt is heightened within the most intimate relationships and is particularly salient in cases of romantic relationship infidelity. Therefore, self-forgiveness may be indicated for romantic partners who have engaged in infidelity. This evidence-based case study examines the treatment of a Caucasian woman in her early 50s who presented with self-unforgiveness following marital infidelity. An 8-week manualized individual counseling program for self-forgiveness was used, which incorporates emotion-focused therapy techniques and principles of positive psychology to facilitate clients' engagement with a 4-component therapeutic model of self-forgiveness—responsibility, remorse, restoration, and renewal. This evidence-based case study demonstrated the importance of emotion-focused techniques in the client's

							emotional recovery, as well as the ways in which the intervention served as a eudaimonic process that resulted in the client's personal and relational well-being. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Coronado, Rogelio A.; Master, Hiral; Bley, Jordan A.; Robinette, Payton E.; Sterling, Emma K.; O'Brien, Michael T.; Henry, Abigail L.; Pennings, Jacquelyn S.; Vanston, Susan W.; Myczkowski, Brittany; Skolasky, Richard L.; Wegener, Stephen T.; Archer, Kristin R.	2022	Patient-Centered Goals After Lumbar Spine Surgery: A Secondary Analysis of Cognitive-Behavioral-Based Physical Therapy Outcomes From a Randomized Controlled Trial	Physical therapy	102	9		OBJECTIVE: The purpose of this study was to examine the association between goal attainment and patient-reported outcomes in patients who engaged in a 6-session, telephone-based, cognitive-behavioral-based physical therapy (CBPT) intervention after spine surgery. METHODS: In this secondary analysis of a randomized trial, data from 112 participants (mean age = 63.3 [SD = 11.2] years; 57 [51%] women) who attended at least 2 CBPT sessions (median = 6 [range = 2-6]) were examined. At each session, participants set weekly goals and used goal attainment scaling (GAS) to report goal attainment from the previous session. The number and type of goals and percentage of goals met were tracked. An individual GAS t score was computed across sessions. Participants were categorized based on goals met as expected (GAS t score ≥ 50) or goals not met as expected (GAS t score < 50). Six- and 12-month outcomes included disability (Oswestry Disability Index), physical and mental health (12-Item Short-Form Health Survey), physical function (Patient-Reported Outcomes Measurement Information System), pain interference (Patient-Reported Outcomes Measurement Information System), and back and leg pain intensity (numeric rating scale). Outcome differences over time between groups were examined with mixed-effects regression. RESULTS: Participants set a median of 3 goals (range = 1-6) at each session. The most common goal categories were recreational/physical activity (36%), adopting a CBPT strategy (28%), exercising (11%), and

							performing activities of daily living (11%). Forty-eight participants (43%) met their goals as expected. Participants who met their goals as expected had greater physical function improvement at 6 months (estimate = 3.7; 95% CI = 1.0 to 6.5) and 12 months (estimate = 2.8; 95% CI = 0.04 to 5.6). No other outcome differences were noted. CONCLUSIONS: Goal attainment within a CBPT program was associated with 6- and 12-month improvements in postoperative physical functioning. IMPACT: This study highlights goal attainment as an important rehabilitation component related to physical function recovery after spine surgery.

Cottis, Tamsin	2017	‘You Can Take it With You’: Transitions and Transitional Objects in Psychotherapy with Children Who have Learning Disabilities	Brit J Psychotherapy (British Journal of Psychotherapy)	33	1	17–30	
Counselman-Carpenter, Elisabeth A.	2018	Efficacy of the flipped classroom to teach play	International Journal of Play Therapy	27	3	146–156	This mixed-methods study, including quantitative and qualitative measures, evaluated how a flipped classroom learning environment that included a hands-on experiential skills lab to teach play therapy improved

		therapy: A mixed-methods study				<p>student's knowledge, attitude, and skills related to play therapy. Participating students (n = 18) completed the Play Therapy Knowledge, Attitudes, and Skills Survey (PTKASS) at the beginning and the end of the course. Students also reflected upon their experience in the skills lab each week in anonymous online feedback journals, which were analyzed at the conclusion of the semester for common themes by multiple coders. Students scores were significantly different on all subscales of the PTKASS: attitude (p = .0012), knowledge (p < .001), with the biggest growth in the skills subscale (p < .001). Through concurrent triangulation, these differences directly correlated to relevant qualitative themes that emerged from student feedback journals. The results of this study indicate strong support for the flipped classroom as an opportunity to develop graduate students' knowledge, attitudes, and skills in play therapy. Cowan, Nelson; Elliott, Emily M.	2023	Deconfounding serial recall: Response timing and the overarching role of grouping	Journal of Experimental Psychology: Learning, Memory, and Cognition	49	2	<p>We used the timing of serial recall in several situations to reveal important aspects of recall groupings that participants construct and the reasons those groupings occur. We examined the timing of responses in the recall of digit strings within two published experiments. Cowan, Saults, Elliott, and Moreno (2002) examined memory for nine-item lists in a way that deconfounded the presentation modality, input versus output serial position (using a varied starting point of recall), memory load from items not yet recalled (using whole vs. partial recall), and the presence or absence of the temporal grouping of the lists into triads. Accuracy was strikingly different in the two modalities, with grouping drastically changing recall of acoustic lists but with little difference between</p>

						grouped versus ungrouped visual lists. Despite the modality difference in recall, the present timing results show that participants imposed a similar grouped structure in recall for both modalities. When errors were made, the original grouping structure still was maintained in the output timing. Cowan et al. (2005, Experiment 1) presented ungrouped acoustic lists of varying lengths in a span task. In this case, there was never a grouping structure presented to the participant and the accuracy data did not reveal evidence of grouping, but we show clear grouping in the timing structure. This grouping structure varied with both the list length and an individual's span. Timing in both experiments shows that a grouping structure is imposed on responses in a manner that is dependent on several factors not present in the stimuli. Cowden, Richard G.; Captari, Laura E.; Chen, Zhuo J.; Kock, Johannes H. de; Houghtaling, Austin		Effectiveness of an intensive experiential group therapy program in promoting mental health and well-being among mass shooting survivors: A practice-based pilot study	Professional Psychology: Research and Practice	53	2	This longitudinal intervention study examines the effectiveness of a 6-day intensive experiential group therapy program for survivors of mass shootings. The sample consisted of 36 participants (83.33% female; Mage = 41.66, SDage = 22.52) who survived a mass shooting episode in the U.S. Self-reported mental health (i.e., PTSD, depression, and anxiety symptoms), physical health (i.e., sleep disturbance, subjective health complaints), and flourishing were assessed at baseline (T0), end of treatment (T1), 1-month follow-up (T2), 3-month follow-up (T3), and 6-month follow-up (T4). Satisfaction with the treatment was evaluated at T1. After controlling for relevant sociodemographic characteristics, multilevel modeling results revealed significant improvements in PTSD ($d = -0.86$, $p d = -0.76$, $p d = -0.89$, $p d = 0.52$, $p = .003$) at T1. There was weak

							evidence in support of an improvement in sleep disturbance from T0 to T1 ($d = -0.30, p = .054$), and the reduction in subjective health complaints was negligible ($d = -0.03, p = .847$). Posttreatment gains were largely maintained at T2 through T4, with some fluctuations and further gains evidenced over time. Treatment satisfaction ratings at the end of treatment were high. The findings of this practice-based study provide preliminary evidence demonstrating the medium-term effectiveness of a group experiential treatment in promoting the mental health and well-being of mass shooting survivors. Cox, Philip; Aella	2020	Whore phobia: The experiences of a dual-training sex worker-psychotherapist	Psychother Politics Int (Psychotherapy and Politics International)	18	2		
Coyne, Alice E.; Constantino, Michael J.; Ravitz, Paula; McBride, Carolina		The interactive effect of patient attachment and social support on early alliance quality in interpersonal psychotherapy	Journal of Psychotherapy Integration	28	1		As an established predictor of favorable patient outcomes across varied forms of psychotherapy, the patient-therapist alliance is widely viewed as the quintessential integrative process variable. Thus, researchers and clinicians are invested in understanding factors that influence alliance quality. Patients' insecure attachment dimensions (i.e., avoidant and anxious) are pandiagnostic patient characteristics that have been shown to relate negatively to the alliance. Although this direct effect is established, little is known about how other patient characteristics interact with attachment dimensions to influence alliance. Using archival data, we examined whether patient-perceived social support satisfaction interacted with both attachment dimensions to predict early alliance in interpersonal psychotherapy

							(IPT) for depression (a treatment centered on attachment relationships, interpersonal events, and social support in conceptualizing and ameliorating depression). This study was exploratory given no prior research on this interaction. Data derived from a naturalistic trial of depressed outpatients (N = 119) receiving 16 IPT sessions. Patient attachment and social support were assessed at baseline; alliance was assessed at Session 3. Data were analyzed with multiple imputation multiple regressions. Results failed to replicate the previous negative main effects of the insecure attachment dimensions on alliance. However, a significant avoidant attachment by social support interaction emerged; alliance quality was lowest for patients who reported more avoidant attachment and higher satisfaction with social supports. Results help clarify conditions under which patients' avoidant attachment influences alliance, and may help IPT therapists identify patients for whom early alliance formation is challenging, thereby placing them at greater risk for negative therapy outcomes. Cradock O'Leary, Julie; Kelley, Donna; Parrish, Cassandra	2020	From swallowing to savoring emotions: A therapeutic assessment case study using the Thurston Cradock Test of Shame as an	Rorschachiana	41	2	181-199	This article presents a Therapeutic Assessment case study of a 48-year-old Catholic nun who was evaluated for concerns related to recurrent depression, difficulty relating to others, trouble following through on tasks, and lack of self-care. Maria was given the Rorschach, MMPI-2-RF, Wartegg Drawing Completion Test, and Thurston Cradock Test of Shame (TCTS). Testing results suggested depression, problems regulating emotion, incongruence between external presentation and internal state, and impaired functional intelligence when negative emotions are triggered. Maria's TCTS protocol indicated a tendency

		assessment intervention					to deflate in the presence of shame or criticism. She used tentative language around emotion, did not access support, and struggled to resolve emotionally charged situations. The TCTS results appeared to access and explain Maria's core difficulties. TCTS Cards 6 and 8 were selected for an assessment intervention session (AIS) designed to help Maria understand what she does with negative feelings. Maria was asked to tell a story focusing on the main character. Through half-steps and affective scaffolding, Maria identified how she "swallows" her negative feelings and "isolates" when emotions are strong. The authors discuss how the AIS helped Maria access her split-off affect, and understand its relation to her symptoms, poor self-care, impaired follow-through, and relational difficulties. Crane, R. S.; Brewer, J.; Feldman, C.; Kabat-Zinn, J.; Santorelli, S.; Williams, J. M. G.; Kuyken, W.	2017	What defines mindfulness-based programs? The warp and the weft	Psychological medicine	47	6	990-999	There has been an explosion of interest in mindfulness-based programs (MBPs) such as Mindfulness-Based Stress Reduction (MBSR) and Mindfulness-Based Cognitive Therapy. This is demonstrated in increased research, implementation of MBPs in healthcare, educational, criminal justice and workplace settings, and in mainstream interest. For the sustainable development of the field there is a need to articulate a definition of what an MBP is and what it is not. This paper provides a framework to define the essential characteristics of the family of MBPs originating from the parent program MBSR, and the processes which inform adaptations of MBPs for different populations or contexts. The framework addresses the essential characteristics of the program and of teacher. MBPs: are informed by theories and practices that draw from a confluence of contemplative traditions, science, and the major disciplines of medicine,

							psychology and education; underpinned by a model of human experience which addresses the causes of human distress and the pathways to relieving it; develop a new relationship with experience characterized by present moment focus, decentering and an approach orientation; catalyze the development of qualities such as joy, compassion, wisdom, equanimity and greater attentional, emotional and behavioral self-regulation, and engage participants in a sustained intensive training in mindfulness meditation practice, in an experiential inquiry-based learning process and in exercises to develop understanding. The paper's aim is to support clarity, which will in turn support the systematic development of MBP research, and the integrity of the field during the process of implementation in the mainstream.
Creed, Torrey A.; Salama, Leah; Slevin, Roisin; Tanana, Michael; Imel, Zac; Narayanan, Shrikanth; Atkins, David C.	2022	Enhancing the quality of cognitive behavioral therapy in community mental health through artificial intelligence generated fidelity feedback (Project AFFECT): a study protocol	BMC health services research	22	1	1177	BACKGROUND: Each year, millions of Americans receive evidence-based psychotherapies (EBPs) like cognitive behavioral therapy (CBT) for the treatment of mental and behavioral health problems. Yet, at present, there is no scalable method for evaluating the quality of psychotherapy services, leaving EBP quality and effectiveness largely unmeasured and unknown. Project AFFECT will develop and evaluate an AI-based software system to automatically estimate CBT fidelity from a recording of a CBT session. Project AFFECT is an NIMH-funded research partnership between the Penn Collaborative for CBT and Implementation Science and Lyssn.io, Inc. ("Lyssn") a start-up developing AI-based technologies that are objective, scalable, and cost efficient, to support training, supervision, and quality assurance of EBPs. Lyssn provides HIPAA-compliant, cloud-based software for secure recording, sharing, and

							<p>reviewing of therapy sessions, which includes AI-generated metrics for CBT. The proposed tool will build from and be integrated into this core platform. METHODS: Phase I will work from an existing software prototype to develop a LyssnCBT user interface geared to the needs of community mental health (CMH) agencies. Core activities include a user-centered design focus group and interviews with community mental health therapists, supervisors, and administrators to inform the design and development of LyssnCBT. LyssnCBT will be evaluated for usability and implementation readiness in a final stage of Phase I. Phase II will conduct a stepped-wedge, hybrid implementation-effectiveness randomized trial (N = 1,875 clients) to evaluate the effectiveness of LyssnCBT to improve therapist CBT skills and client outcomes and reduce client drop-out. Analyses will also examine the hypothesized mechanism of action underlying LyssnCBT. DISCUSSION: Successful execution will provide automated, scalable CBT fidelity feedback for the first time ever, supporting high-quality training, supervision, and quality assurance, and providing a core technology foundation that could support the quality delivery of a range of EBPs in the future. TRIAL REGISTRATION: ClinicalTrials.gov; NCT05340738 ; approved 4/21/2022.</p>
<p>Crenshaw, Alexander O.; Libet, Julian; Petty, Karen; Teves, Jenna B.; Huang, Alice; Mitchell, Jerez</p>	2023	<p>Subjective emotion trajectories in couple therapy and associations with improvement in</p>	Family process	62	4	1542–1554	<p>Existing couple therapies are generally effective for reducing romantic relationship distress and divorce, but therapy outcomes remain poor for many. Outcomes can be improved through greater understanding of session-by-session therapeutic processes, particularly in real-world treatment settings. Modern couple therapy models commonly emphasize the importance of emotional experiences as key change processes, yet few empirical studies have tested the merits of this focus. The present</p>

		relationship satisfaction					study addresses this limitation by examining trajectories of subjective emotions and their association with change in a key relationship outcome, relationship satisfaction, among military veterans and their partners at a VA Medical Center. Partners rated their relationship satisfaction prior to couple therapy sessions and subjective emotions immediately after sessions. Consistent with hypotheses, both hard (e.g., anger) and soft (e.g., sadness) negative emotions decreased significantly over the course of therapy. Those couples with greater decreases in hard negative, but not soft negative, emotions showed significantly more improvement in relationship satisfaction. Positive emotions did not significantly change across couples in general, but those couples whose positive emotions did increase also showed more improvement in relationship satisfaction. These results suggest change in subjective emotions may be one process underlying improvement in couple therapy and lend empirical support to the emphasis on emotion-based change processes underlying acceptance-based and emotion-focused couple therapies.
Critchfield, Kenneth L.; Mackaronis, Julia E.; Benjamin, Lorna Smith	2017	Characterizing the integration of CBT and psychodynamic techniques in interpersonal reconstructive therapy for patients with severe and comorbid	Journal of Psychotherapy Integration		15 73- 36 96(Ele ctr oni c), 10 53- 04	460-475	A “unifying” approach to psychotherapy integration (Magnavita & Anchin, 2014) uses a metatheoretical framework to delineate mechanisms of psychopathology and change that cut across traditional theoretical orientations. Interpersonal Reconstructive Therapy (IRT; Benjamin, 2006, in press) is 1 such approach to treatment. In IRT, therapists view clinical symptoms and problems as natural consequences of maladaptive interpersonal patterns related to safety and threat that patients have learned and internalized in the context of close attachment relationships. Therapists may use

		personality pathology			79(Print)		<p>interventions from any tradition so long as use is consistent with the individual patient's case formulation and underlying treatment principles. Prior work has suggested that adherence to IRT principles, particularly a focus on internalized attachments, has strong links to retention and outcome (Critchfield et al., 2011). In the present work, 19 outpatient IRT sessions were sampled from a research archive of therapies conducted with complex cases identified as comorbid, often rehospitalized, dysfunctional, and suicidal (CORDS). Included were 9 sessions showing high adherence to IRT principles and 10 contrasting low adherence sessions. Trained raters applied the Comparative Psychotherapy Process Scale (CPPS; Hilsenroth, Blagys, Ackerman, Bonge, & Blais, 2005). As expected, adherent IRT sessions contained both psychodynamic–interpersonal and cognitive–behavioral techniques in ways that reflected integrative theory. Less expected was that rater reliability in identifying standard techniques varied systematically as a function of IRT adherence. This last finding has broad implications for psychotherapy integration research, especially with principles-based, unified models. (PsycINFO Database Record (c) 2018 APA, all rights reserved)</p>
Crosetti, Anne-Sophie	2020	The 'Converted Unbelievers': Catholics in Family Planning in French-Speaking Belgium (1947-73)	Medical history	64	2	267–286	<p>This paper looks at the journey of eleven counsellors in marital counselling centres in French-speaking Belgium, from the creation of the centres in 1953, to the 1970s, when contraception became legal, and abortion became a public issue. At the time of Humanae Vitae, groups of volunteers, working within Catholic organisations where counselling took place, began to structure their activity around Carl Rogers's ethics of client-centred therapy, placing their religious ideology in a secondary position to</p>

							focus on the problems experienced by the couples and women they were receiving in the centres. These were often challenges they were experiencing themselves in their own lives. The reiteration of the Catholic orthodox view on contraception through Humanae Vitae marked a gap between the counsellors and the Church. This contribution questions the identity-related tension of Catholics working in conjugal counselling centres and the type of commitments they made to both the conjugal centres and the Church in a moment where family planning was debated both in the Church and politically.
Crowe, Marie; Manuel, Jenni; Carlyle, Dave; Lacey, Cameron	2023	Psilocybin-assisted psychotherapy for treatment-resistant depression: Which psychotherapy?	Int J Mental Health Nurs (International Journal of Mental Health Nursing)	32	6	1766–1772	Abstract This perspective paper explores the choice of psychotherapy for psilocybin-assisted psychotherapy for treatment-resistant depression. There is evidence to support the use of some psychotherapies in treating ?treatment-resistant? depression, and emerging evidence for the efficacy of psilocybin. The next step which is the focus of this paper is to identify psychotherapies that are both effective and congruent with the psilocybin experience. The evidence for the efficacy of the psychotherapies is drawn from a Cochrane review and the analysis of their congruence with the psilocybin experience is drawn from a qualitative meta-synthesis of the experience of psilocybin. The paper will examine whether three one-to-one psychotherapies identified as effective in the treatment of treatment-resistant depression are compatible with the psilocybin experience. Each psychotherapy will be examined in relation to its congruence with the qualitative evidence that suggests the choice of psychotherapy needs to give priority to the subjective experience, facilitate emotional processing, support connectedness with others, acceptance of the self as emotional and support change

							based on the person's insights into their relationships with others and the world in which they live. We conclude that interpersonal psychotherapy and intensive short-term dynamic psychotherapy align with that experience, although others are currently being trialled.
Cuijpers, Pim		Four decades of outcome research on psychotherapies for adult depression: An overview of a series of meta-analyses	Canadian Psychology / Psychologie canadienne	58	1		In the past 4 decades about 500 randomized trials have examined the effects of psychological treatments of adult depression. In this article the results of a series of meta-analyses of these trials are summarised. Several types of psychotherapy have been examined, including cognitive behaviour therapy, behavioural activation therapy, interpersonal psychotherapy, problem-solving therapy, nondirective supportive therapy, and short-term psychodynamic psychotherapy. All therapies are effective and there are no significant differences between treatments. Psychotherapies are about equally effective as pharmacotherapy, and combined treatments are more effective than either of these alone. Therapies are also effective in specific target groups, such as older adults, college students, patients with general medical disorders, but may be somewhat less effective in chronic depression, and in patients with comorbid substance use disorders. Treatments are effective when delivered in individual, group, and guided self-help format. The effects of psychotherapies have been overestimated because of the low quality of many trials and due to publication bias. Future research should not be aimed at the development of new psychotherapies for depression, on specific treatment formats or on therapies in specific populations, because the evidence indicates that all types and formats with human involvement are effective in all specific target groups. Future research should instead focus on a further reduction of the disease burden of depression.

							Specifically, it should focus on the possibilities of preventing the onset of depressive disorders, treatments of chronic and treatment-resistant depression, relapse prevention, and scaling up treatments, for example by using more guided self-help interventions. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Cuijpers, Pim; Ebert, David D.; Acarturk, Ceren; Andersson, Gerhard; Cristea, Ioana A.	2016	Personalized Psychotherapy for Adult Depression: A Meta-Analytic Review	Behavior therapy	47	6	966–980	Personalized medicine is aimed at identifying which characteristics of an individual predict the outcome of a specific treatment, in order to get a better match between the individual and the treatment received. We conducted a systematic review and meta-analysis of randomized trials comparing two psychotherapies directly in a group of depressed patients with a specific characteristic. We focused on the six most examined types of psychotherapy for adult depression. Our searches resulted in 41 studies with 2,741 patients who met inclusion criteria. These 41 studies examined 27 specific characteristics of patients. Power calculations indicated that we would need 4 studies for each characteristic to find a clinically relevant effect size set at $g = 0.50$ and 16 studies for an effect size of 0.24. Only 3 patient characteristics were found to have sufficient power and to significantly moderate treatment outcomes. Cognitive-behavioral therapy was found to be more effective than other therapies in older adults ($g = 0.29$), in patients with comorbid addictive disorders ($g = 0.31$), and in university students ($g = 0.46$). Risk of bias was considerable in most of the included studies. It was estimated that it will take another 326 years to have sufficient statistical power for showing an effect size of $g = 0.50$ of the 27 characteristics, and 1,372 years to show an effect size of 0.24. Although several dozens of studies have compared the effects of psychotherapies in specific target groups, we will need to develop more powerful

							alternatives to comparative outcome studies in order to identify personalized treatments for depression.
Cuijpers, Pim; Karyotaki, Eirini	2021	The effects of psychological treatment of perinatal depression: an overview	Archives of women's mental health	24	5	801–806	Perinatal depression is an important public health problem. Psychological interventions play an essential role in the treatment of depression. In the current paper, we will present the results of a series of meta-analyses on psychological treatments of perinatal depression. We report the results of a series of meta-analyses on psychological treatments of depression, including perinatal depression. The meta-analyses are based on a database of randomized trials on psychotherapies for depression that has been systematically developed and updated every year. Psychological interventions are effective in the treatment of perinatal depression with a moderate effect size of $g = 0.67$, corresponding with a NNT of about 4. These effects were still significant at 12 months after the start of the treatment. These interventions also have significant effects on social support, anxiety, functional impairment, parental stress, and marital stress. Possibly the effects are overestimated because of the use of waiting list control groups, the low quality of the majority of trials and publication bias. Research on psychotherapies for depression in general has shown that there are no significant differences between the major types of therapy, except for non-directive counseling that may have somewhat smaller effects. CBT can also be delivered in individual, group, telephone, and guided self-help format. Interventions in subthreshold depression are also effective and may prevent the onset of a full-blown depressive disorder, while therapies may be less effective in chronic depression. Psychological interventions are effective and

							deserve their place as first-line treatment of perinatal depression.
Cuijpers, Pim; Karyotaki, Eirini; Wit, Leonore de; Ebert, David D.	2020	The effects of fifteen evidence-supported therapies for adult depression: A meta-analytic review	Psychotherapy research : journal of the Society for Psychotherapy Research	30	3	279–293	Objective: In the past decades, many different types of psychotherapy for adult depression have been developed. Method: In this meta-analysis we examined the effects of 15 different types of psychotherapy using 385 comparisons between a therapy and a control condition: Acceptance and commitment therapy, mindfulness-based cognitive behavior therapy (CBT), guided self-help using a self-help book from David Burns, Beck's CBT, the "Coping with Depression" course, two subtypes of behavioral activation, extended and brief problem-solving therapy, self-examination therapy, brief psychodynamic therapy, non-directive counseling, full and brief interpersonal psychotherapy, and life review therapy. Results: The effect sizes ranged from $g = 0.38$ for the "Coping with Depression" course to $g = 1.10$ for life review therapy. There was significant publication bias for most therapies. In 70% of the trials there was at least some risk of bias. After adjusting studies with low risk of bias for publication bias, only two types of therapy remained significant (the "Coping with Depression" course, and self-examination therapy). Conclusions: We conclude that the 15 types of psychotherapy may be effective in the treatment of depression. However, the evidence is not conclusive because of high levels of heterogeneity, publication bias, and the risk of bias in the majority of studies.
Cuijpers, Pim; Miguel, Clara; Ciharova, Marketa; Harrer,	2024	Non-directive supportive therapy for depression: A	Journal of affective disorders	349		452–461	BACKGROUND: Non-directive supportive therapy (NDST) is an important treatment of adult depression, but no recent meta-analysis has integrated the randomized trials examining its effects. METHODS: We conducted a meta-analysis comparing NDST to control conditions and to

Mathias; Karyotaki, Eirini		meta-analytic review					<p>other therapies, by using an existing database of randomized trials of psychological treatments of depression in adults. This database was built through searches in PubMed, PsycINFO, Embase and the Cochrane Library. RESULTS: 48 randomized controlled trials (5075 participants), with 20 comparisons between NDST and a control group and 49 comparisons between NDST and another psychotherapy were included. Random effects meta-analyses found an effect size of NDST compared with control conditions of $g = 0.53$ (95 % CI, 0.34; 0.72) with moderate heterogeneity ($I(2) = 51$; 95 % CI: 18; 71; $PI = -0.02$ to 1.09). NDST was less effective than other therapies ($g = -0.21$; 95 % CI: -0.31; -0.11). The difference with other therapies was significantly larger in studies in which NDST was used as a control group ($p = .003$). There was no significant difference between NDST and other therapies in which NDST was not used as a control group ($k = 14$; $g = -0.05$; 95 % CI: -0.17; 0.07). CONCLUSIONS: NDST probably is an effective treatment of depression. The effects may be somewhat smaller than those of other therapies, but that may also be an artefact, because NDST is often used as a control group and may be designed as an "intent-to-fail" intervention in some studies.</p>
Cuijpers, Pim; Quero, Soledad; Noma, Hisashi; Ciharova, Marketa; Miguel, Clara; Karyotaki, Eirini; Cipriani, Andrea; Cristea,	2021	Psychotherapies for depression: a network meta-analysis covering efficacy, acceptability and long-term	World psychiatry : official journal of the World Psychiatric Association (WPA)	20	2	283–293	<p>The effects of psychotherapies for depression have been examined in several hundreds of randomized trials, but no recent network meta-analysis (NMA) has integrated the results of these studies. We conducted an NMA of trials comparing cognitive behavioural, interpersonal, psychodynamic, problem-solving, behavioural activation, life-review and "third wave" therapies and non-directive supportive counseling with each other and with care-as-usual, waiting list and pill placebo control conditions.</p>

Ioana A.; Furukawa, Toshi A.		outcomes of all main treatment types				<p>Response (50% reduction in symptoms) was the primary outcome, but we also assessed remission, standardized mean difference, and acceptability (all-cause dropout rate). Random-effects pairwise and network meta-analyses were conducted on 331 randomized trials with 34,285 patients. All therapies were more efficacious than care-as-usual and waiting list control conditions, and all therapies - except non-directive supportive counseling and psychodynamic therapy - were more efficacious than pill placebo. Standardized mean differences compared with care-as-usual ranged from -0.81 for life-review therapy to -0.32 for non-directive supportive counseling. Individual psychotherapies did not differ significantly from each other, with the only exception of non-directive supportive counseling, which was less efficacious than all other therapies. The results were similar when only studies with low risk of bias were included. Most therapies still had significant effects at 12-month follow-up compared to care-as-usual, and problem-solving therapy was found to have a somewhat higher long-term efficacy than some other therapies. No consistent differences in acceptability were found. Our conclusion is that the most important types of psychotherapy are efficacious and acceptable in the acute treatment of adult depression, with few significant differences between them. Patient preference and availability of each treatment type may play a larger role in the choice between types of psychotherapy, although it is possible that a more detailed characterization of patients with a diagnosis of depression may lead to a more precise matching between individual patients and individual psychotherapies.</p>

<p>Cumming, Paul; Scheidegger, Milan; Dornbierer, Dario; Palner, Mikael; Quednow, Boris B.; Martin- Soelch, Chantal</p>	<p>2021</p>	<p>Molecular and Functional Imaging Studies of Psychedelic Drug Action in Animals and Humans</p>	<p>Molecules (Basel, Switzerland)</p>	<p>26</p>	<p>9</p>	<p>Hallucinogens are a loosely defined group of compounds including LSD, N,N-dimethyltryptamines, mescaline, psilocybin/psilocin, and 2,5-dimethoxy-4-methamphetamine (DOM), which can evoke intense visual and emotional experiences. We are witnessing a renaissance of research interest in hallucinogens, driven by increasing awareness of their psychotherapeutic potential. As such, we now present a narrative review of the literature on hallucinogen binding in vitro and ex vivo, and the various molecular imaging studies with positron emission tomography (PET) or single photon emission computer tomography (SPECT). In general, molecular imaging can depict the uptake and binding distribution of labelled hallucinogenic compounds or their congeners in the brain, as was shown in an early PET study with N(1)-([11C]-methyl)-2-bromo-LSD ([11C]-MBL); displacement with the non-radioactive competitor ketanserin confirmed that the majority of [11C]-MBL specific binding was to serotonin 5-HT(2A) receptors. However, interactions at serotonin 5HT(1A) and other classes of receptors and pleotropic effects on second messenger pathways may contribute to the particular experiential phenomenologies of LSD and other hallucinogenic compounds. Other salient aspects of hallucinogen action include permeability to the blood-brain barrier, the rates of metabolism and elimination, and the formation of active metabolites. Despite the maturation of radiochemistry and molecular imaging in recent years, there has been only a handful of PET or SPECT studies of radiolabeled hallucinogens, most recently using the 5-HT(2A/2C) agonist N-(2-[(11)CH(3)O]-methoxybenzyl)-2,5-dimethoxy-4-bromophenethylamine ([11C]Cimbi-36). In addition to PET studies of target</p>
---	-------------	--	---	-----------	----------	--

							engagement at neuroreceptors and transporters, there is a small number of studies on the effects of hallucinogenic compounds on cerebral perfusion ([¹⁵ O]-water) or metabolism ([¹⁸ F]-fluorodeoxyglucose/FDG). There remains considerable scope for basic imaging research on the sites of interaction of hallucinogens and their cerebrometabolic effects; we expect that hybrid imaging with PET in conjunction with functional magnetic resonance imaging (fMRI) should provide especially useful for the next phase of this research.
Cunha, Carla; Mendes, Ins; Ribeiro, Antnio P.; Angus, Lynne; Greenberg, Leslie S.; Gonaves, Miguel M.	2017	Self-narrative reconstruction in emotion-focused therapy: A preliminary task analysis	Psychotherapy research: journal of the Society for Psychotherapy Research	27	6	692–709	This research explored the consolidation phase of emotion-focused therapy (EFT) for depression and studies-through a task-analysis method-how client-therapist dyads evolved from the exploration of the problem to self-narrative reconstruction. Innovative moments (IMs) were used to situate the process of self-narrative reconstruction within sessions, particularly through reconceptualization and performing change IMs. We contrasted the observation of these occurrences with a rational model of self-narrative reconstruction, previously built. This study presents the rational model and the revised rational-empirical model of the self-narrative reconstruction task in three EFT dyads, suggesting nine steps necessary for task resolution: (1) Explicit recognition of differences in the present and steps in the path of change; (2) Development of a meta-perspective contrast between present self and past self; (3) Amplification of contrast in the self; (4) A positive appreciation of changes is conveyed; (5) Occurrence of feelings of empowerment, competence, and mastery; (6) Reference to difficulties still present; (7) Emphasis on the loss of centrality of the problem; (8) Perception of change

							as a gradual, developing process; and (9) Reference to projects, experiences of change, or elaboration of new plans. Central aspects of therapist activity in facilitating the client's progression along these nine steps are also elaborated.
Currier, Joseph M.; McDermott, Ryon C.; McCormick, Wesley H.	2017	Mental health treatment-related stigma and professional help seeking among student veterans	Psychological Services	14	4		Record numbers of military veterans are enrolling at colleges/universities across the United States. Although a substantive subset might suffer from mental health problems, the majority of these students might not be amenable to utilizing services. The purpose of this study was to examine the role of treatment-related stigma in intentions to seek professional help among undergraduate student veterans at a university on the U.S. Gulf Coast. Focusing on 251 veterans and a gender-matched comparison group of 251 nonveterans, student veterans endorsed higher probabilities of seeking care from physicians ($d = .77$) and psychologists or other professionals ($d = .67$). In addition, nonveteran students had greater self-stigma about seeking help ($d = -.27$) but veterans had more negative beliefs about treatment efficacy ($d = 1.07$). When compared with veterans who did not exceed clinical thresholds, those with a probable need for treatment had more stigma ($ds = .63$). Multivariate analyses also revealed an inverse main effect of self-stigma on intentions to seek help from both professional categories. However, military experience differentially moderated associations between treatment-related beliefs and intentions to seek mental health services. Finally, exploratory analyses identified that student veterans were most likely to engage in therapy/counseling at a Veterans Affairs Medical Center or Clinic, Vet Center, or other noninstitutionally sponsored settings in the community (e.g., private

							practices, faith-based organizations). Looking ahead, these findings will inform research and the provision of services for addressing the mental health needs of this substantive subpopulation of college students in the United States. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Currier, Joseph M.; Pearce, Michelle; Carroll, Timothy D.; Koenig, Harold G.	2018	Military veterans' preferences for incorporating spirituality in psychotherapy or counseling	Professional Psychology: Research and Practice	49	1	39-47	Amassing research findings suggests that religious faith and/or spirituality (R/S) can both help and hinder recovery from mental health conditions that might prompt military veterans to seek psychotherapy or counseling. As such, there is increasing interest among psychologists and other professionals working with military populations in the helpfulness of addressing the R/S domain. However, research has yet to examine veterans' actual preferences for integrating R/S in their treatment. Drawing on two samples with heterogeneity in R/S backgrounds and military-related experiences, results revealed that veterans generally viewed incorporating R/S in psychotherapy or counseling as "somewhat" important. When compared to more concrete approaches assessed in the study, they also gave greater importance to interventions that assumed an exploratory and affirming approach to R/S. In addition, when focusing on veterans with a probable need for treatment for posttraumatic stress disorder (PTSD) and/or major depressive disorder (MDD) at the time of the study, other results illuminated several factors that might shape these preferences. Namely, veterans from ethnic minority groups and those who were highly religious and/or had a strong belief in God's existence were more interested in a spiritually integrative treatment. This final set of analyses also revealed that veterans with clinical levels of PTSD/MDD symptoms who were experiencing R/S struggles endorsed

							stronger preferences, particularly with respect to moral struggles. Overall, these findings support the need for a patient-centered approach with veterans in which clinicians are not ignorant of R/S concerns but also do not assume that this domain should be targeted in every case. Currier, Joseph M.; Stevens, L. Taylor; McDermott, Ryon C.; Hinkel, Hannah M.; Salcone, Sarah; Davis, Edward B.; Lacey, Ethan K.; Park, Crystal L.	2022	Exploring the roles of god representations in spiritual struggles among Christians seeking spiritually integrated psychotherapies	Spirituality in Clinical Practice			No Paginat ion Specified -No Paginat ion Specified	The overall purpose of this study was to examine the role of core dimensions of theistic relational spirituality (doctrinal God representations, experiential God representations, and doctrinal-experiential congruence) in divine spiritual struggles among Christians engaging in spiritually integrated psychotherapies. In total, 189 clients completed a modified version of Johnson et al.'s (2015) A/B God Scales as well as quantitative and qualitative assessments of divine spiritual struggles. When accounting for religious commitment and depression symptoms as covariates, clients with stronger authoritarian and benevolent representations of God were more and less likely, respectively, to be experiencing spiritual struggles (assessed with Exline et al.'s 2014 Religious and Spiritual Struggles Scale [RSS]). In addition, doctrinal-experiential discrepancy in benevolent God representations was associated with RSS scores as well as qualitative themes reflecting ways in which religious attachment provided comfort (e.g., stronger relationship with God, finding meaning or purpose, seeking support from God) and/or strain (e.g., disconnect or strain with God, feeling punished by God, reappraisal of divine power) in clients' lives. Specifically, clients who endorsed greater theological or conceptual knowledge of a loving God relative to their felt experience of divine love, on average, reported more spiritual struggles and were less

							able to draw comfort from their religious attachment bond at the time of the study. Findings affirm the need for further research on doctrinal-experiential congruence and support the value of clinicians conducting spiritually integrated psychotherapies with Christians to adequately attend to benevolent and authoritarian God representations that might facilitate or hinder their clients' progress in treatment. Curtis, David F.; Elkins, Sara R.; Duran, Patty; Venta, Amanda C.	2016	Promoting a climate of reflective practice and clinician self-efficacy in vertical supervision	Training and Education in Professional Psychology	10	3	133-140	Supervision in psychology, particularly related to psychotherapy, aims to promote clinical and professional competencies for learners while ultimately ensuring the effective and ethical delivery of patient care. Although clinical psychologists receive intensive education and training in reflective practices for psychotherapy, they typically receive little preparation for applying these practices to clinical supervision. A task force of the American Psychological Association recently released a comprehensive set of clinical supervision guidelines asserting the essential role of reflective communication in clinical supervisory practice (APA, 2015). The purpose of this paper is to introduce ways of incorporating reflective practice into clinical supervision in order to enhance the learner's clinical self-efficacy and independence. First presented is an operational definition of reflective practices accompanied by illustrations of ways in which these practices can extend the quality of evidence-based clinical interventions. Second, a vertical supervision model is introduced, and a variety of supervision modalities for enhancing reflective practices are presented. Finally, the implications of these processes for scaffolding the development of clinician self-efficacy for a range of learners from a variety of

							disciplines are discussed. These processes are highlighted further within a series of personal reflections shared from clinicians across these different developmental stages. (PsycINFO Database Record (c) 2017 APA, all rights reserved)
Curtis, David F.; Heath, Corey L.; Hogan, William J.	2021	Child skills training for attention-deficit/hyperactivity disorder (ADHD): A randomized controlled trial of structured dyadic behavior therapy (SDBT)	Psychotherapy	58	1	68–80	This pilot study examined structured dyadic behavior therapy (SDBT) as a novel, child skills training intervention for attention-deficit/hyperactivity disorder (ADHD). The purpose of this study was to (a) pilot the feasibility of SDBT, a manualized, child skills training intervention, (b) determine the potential clinical benefits of SDBT as an independent psychotherapy for ADHD, and (c) examine parents' intervention acceptability. Children of 8-12 years of age with ADHD-combined type (N = 34) were randomly assigned to either SDBT or an "attention control" condition receiving child-centered dyadic therapy (CCDT). SDBT targeted high-frequency behavioral and social demands often challenging for children with ADHD. CCDT provided nondirective, experiential psychotherapy without any contingency management methods. Descriptive data revealed a high level of treatment attendance and completion (90%) for both conditions. General linear modeling techniques (multivariate analysis of variance) examined group differences in ADHD outcomes. Results indicated statistically significant differences between the two groups, with greater ADHD symptom reduction for SDBT (Wilks' $\lambda = .61$), $F(3, 30) = 6.36$, $p = .002$, $\eta(p)^2 = .39$. SDBT also demonstrated clinically meaningful changes, with ADHD symptom severity reduced below categorical levels of functional impairment. Despite superior behavioral outcomes for SDBT, intervention acceptability did not significantly differ for the two psychotherapies. Results support SDBT as a

							feasible, clinically promising, and acceptable intervention for ADHD. Parent satisfaction ratings suggest dyadic therapies may benefit participants beyond symptom reduction. Implications for intervention portability and treating ADHD without direct adult participation are discussed. (PsycInfo Database Record (c) 2021 APA, all rights reserved).
Cwik, Jan Christopher; Teismann, Tobias	2017	Misclassification of Self-Directed Violence	Clinical psychology & psychotherapy	24	3	677–686	<p>BACKGROUND Inconsistent nomenclature and classification of suicidal behaviour have plagued the field of suicidology for a long time. Recently, the United States Centers for Disease Control (CDC) advocated for the usage of a specific classification system. Aim of the current study was to determine the extent of misdiagnosed acts of self-directed violence—controlling for the level of expertise in psychology/psychotherapy. Additionally, the effect of gender and diagnosis on misclassifications was assessed.</p> <p>METHOD A total of 426 participants (laypersons, psychology students, psychotherapists-in-training, licensed psychotherapists) were presented with an array of case vignettes describing different acts of self-directed violence (e.g., non-suicidal self-directed violence, suicide attempt, suicide ideation) and were asked to make a classification. Gender and given diagnosis were varied systematically in two vignettes.</p> <p>RESULTS Overall 51.6% of the cases were misclassified (according to the Self-Directed Violence Classification System). The level of expertise was almost unrelated to classification correctness. Yet, psychotherapists were more confident about their judgments. Female gender of the character</p>

							<p>described in the vignette and an ascribed diagnosis of Borderline Personality Disorder were associated with higher misclassification rates.</p> <p>LIMITATIONS</p> <p>The validity of case vignettes is discussible.</p> <p>CONCLUSIONS</p> <p>The results highlight the importance of more methodological and diagnostic training of psychologists regarding suicidal issues. Copyright © 2016 John Wiley & Sons, Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Misclassification of non-suicidal and suicidal events is common. Expertise is only weakly associated with classification correctness. Misclassification of suicide attempts occurs more often in women. Misclassification of suicide attempts occurs more often in Borderline Personality Disorder. The use of standardized diagnostic tools in relation to self-directed violence is highly recommended.</p>
Cyniak-Cieciura, Maria; Białaszek, Wojciech; Dudek, Joanna; Ostaszewski, Paweł	2023	Temperament, life satisfaction, and the role of psychological flexibility: Preliminary study applying the person-centered approach	Journal of Individual Differences	44	4	223–233	<p>Temperament is related to well-being. Establishing mediators of this relationship, especially mediators which can be influenced through psychological interventions, may contribute to tailoring these interventions to people’s needs determined by temperament. Psychological flexibility may be considered such a mediator. This study aims to examine the relationships between temperament traits and structures, satisfaction with life, and psychological flexibility, with the latter as a possible mediator of the relationship between temperament structures and life satisfaction. 538 participants (18–93 years old) took part in the study. They filled a set of self-reported questionnaires. Psychological flexibility explained a significant part of the variance in life</p>

							satisfaction above and beyond temperament traits. People with harmonized temperament structures and higher stimulation processing capabilities (sanguine) exhibited higher psychological flexibility and satisfaction with life. Three temperament structures: phlegmatic, choleric, and melancholic in comparison to sanguine were found to be linked to lower satisfaction with life through lower psychological flexibility. The results suggest a meaningful role of stimulation processing capabilities in the development of both psychological flexibility and satisfaction with life. Cyr, Francine; Poitras, Karine; Godbout, Élisabeth	2020	An Interdisciplinary Case Management Protocol for Child Resistance or Refusal Dynamics†	J. Psychiatr. Ment. Health Nurs. (Journal of psychiatric and mental health nursing)	58	2	560–575	High-conflict parental separation cases associated with child's estrangement or contact refusal take an unusually large amount of court time and generate high emotional costs for parents and children. This paper reports on a study of a research-based pilot project and protocol, called the Parenting Conflict Resolution (PCR), which is intended to reduce parental conflict, improve interparental communication, and support or restore the parent-child relationship. The protocol was developed at the Superior Court in Quebec City (Canada), and involves single judge case management, and lawyers' commitment to have the child's best interests as their primary consideration and to guide their clients to trust the process. The assigned judge and lawyers have the ongoing involvement of a mandated psychotherapist, taking a family systems approach with the case. The PCR also requires the parents to participate in a psycho-educational, introspective group program to work on co-parenting and communication skills. Ongoing communication between the professionals involved in the PCR is required to ensure cohesion and accountability.

							<p>This pilot project was implemented with 10 high-conflict families, 6 of which presented with the child's resistance or refusal to see one parent. A qualitative data study was undertaken into the experiences of all the participants. The most salient result is the resumption of parent-child contact in all six contact refusal cases. Discussion highlights key elements to successfully address these cases: (a) interdisciplinary program delivery, (b) systemic understanding of the contact problems, (c) focus on the child's best interest, (d) single judge assigned to the case, (e) lawyers' support of the parents' participation, and (f) psychotherapist reporting to the court.</p>
Czekóová, Kristína; Shaw, Daniel J.; Urbánek, Tomáš	2018	Personality systems, spirituality, and existential well-being: A person-centered perspective	Psychology of Religion and Spirituality	10	4	307-317	<p>Recent research on the salutogenic benefits of spirituality and religiosity has yielded inconsistent findings. It is suggested that such discrepancies reflect individual differences in personality, but this cannot be investigated with variable-driven approaches. The present study measured the influence of personality on the relationship between spirituality and existential well-being (EWB) from the perspective of Personality Systems Interaction theory—an approach focused on functional relationships between cognitive and affective systems, using Latent Profile Analysis. Three major results emerged: First, we identified discrete Analytical, Intuitive, and Flexible personality profiles resembling closely the prototypes reported elsewhere. Second, while preferences for intuitive cognitive processing resulted in high scores on all dimensions of spirituality and EWB, the reverse was true for individuals prone to analytical information processing, replicating previous research. Third, EWB operates independently from other spirituality dimensions, and relates differentially to distinct</p>

							personality profiles. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Da Finger, Igor Rosa; Freitas, Breno Irigoyen de; Da Oliveira, Margareth Silva	2020	Psychological inflexibility in overweight and obese people from the perspective of acceptance and commitment therapy (ACT)	Eating and weight disorders : EWD	25	1	169–175	<p>PURPOSE: To identify the psychological inflexibility (PI) processes (experiential avoidance, cognitive fusion, poor contact with the present moment, unclear personal values and lack of commitment to action) associated with body mass index (BMI), depression, anxiety and stress symptoms and binge eating in overweight and obese people by drawing on the acceptance and commitment therapy (ACT) framework. METHODS: A cross-sectional study of 243 people with a BMI of at least 25 and aged from 18 to 60 years old. The following instruments were used: Acceptance and Action Questionnaire II (AAQ-II), Acceptance and Action Questionnaire-Weight (AAQ-W), Valued Living Questionnaire (VLQ), Cognitive Fusion Questionnaire (CFQ-7), Cognitive Fusion Questionnaire-Body Image (CFQ-BI), Mindful Eating Questionnaire (MEQ), Binge Eating Scale (BES) and Depression, Anxiety and Stress Scale (DASS-21). Data were analyzed using one-way ANOVA and t tests. RESULTS: There were no differences between BMI categories with respect to PI variables, but PI was positively related to the severity of binge eating and to symptoms of depression, anxiety and stress. CONCLUSION: The development of interventions focused on psychological inflexibility can be useful for the treatment of symptoms associated with overweight and obesity. LEVEL OF EVIDENCE: Level V, cross-sectional descriptive study.</p>
Da Ponte, Guida; Ouakinin, Sílvia; Santo, Jorge Espírito;	2020	Process of therapeutic changes in Meaning-Centered Group	Palliative & supportive care	18	3	254–262	<p>OBJECTIVE: The aim was to understand the processes of therapeutic changes in Meaning-Centered Group Psychotherapy (MCGP) in a Portuguese sample. METHOD: Adult cancer patients with distress motivated to participate in MCGP were identified; descriptive and</p>

<p>Amorim, Inês; Gameiro, Zita; Fitz-Henley, Mindi; Breitbart, William</p>		<p>Psychotherapy adapted to the Portuguese language: A narrative analysis</p>				<p>narrative analyses were performed on the session content. RESULTS: The sample had 24 participants (mean age: 63.43 years); the majority were females (75%), with a median academic degree (54%). Breast cancer was most frequent (67%) at the localized stage (71%). The narrative analysis defined seven categories according to the MCGP themes. In "Moments with Meaning (MwM)," the most relevant dimensions were related to interpersonal relations, the moment of diagnosis, and personal achievements. This category established relations with almost all other categories, as did the category "historical sources of meaning (SoM)." The category "identity before and after cancer diagnosis" was only related to "attitudinal SoM" and "transitions." Historical SoM had two dimensions, "past" and "present and future" legacies, in which prominent topics related to family, childhood, achieved goals, and values to pass to others explored. Attitudinal SoM established relations only with the category "creative SoM," in which "courage" and "responsibility" were the main dimensions, which were also related to "MwM," "historical," and "attitudinal SoM." Experiential SoM, with the main dimension "love," was related to "MwM" and "historical SoM." Transitions only established relations with "historical SoM" and "identity before and after cancer." SIGNIFICANCE OF RESULTS: The findings that "MwM" and "historical SoM" were the categories which established a solid pattern of relations suggest that these are the main psychotherapy topics that can have more influence for the participants; one explanation is that these categories imply a concrete way of thinking, which is easier to understand. This process of therapeutic changes must be integrated in a cultural</p>
--	--	---	--	--	--	--

							context, as it is well known to have an impact upon the "meaning" of life.
Dadomo, Harold; Grecucci, Alessandro; Giardini, Irene; Ugolini, Erika; Carmelita, Alessandro; Panzeri, Marta	2016	Schema Therapy for Emotional Dysregulation: Theoretical Implication and Clinical Applications	Frontiers in psychology	7		1987	The term emotional dysregulation refers to an impaired ability to regulate unwanted emotional states. Scientific evidence supports the idea that emotional dysregulation underlies several psychological disorders as, for example: personality disorders, bipolar disorder type II, interpersonal trauma, anxiety disorders, mood disorders and post-traumatic stress disorder. Emotional dysregulation may derive from early interpersonal traumas in childhood. These early traumatic events create a persistent sensitization of the central nervous system in relation to early life stressing events. For this reason, some authors suggest a common endophenotypical origin across psychopathologies. In the last 20 years, cognitive behavioral therapy has increasingly adopted an interactive-ontogenetic view to explain the development of disorders associated to emotional dysregulation. Unfortunately, standard Cognitive Behavior Therapy (CBT) methods are not useful in treating emotional dysregulation. A CBT-derived new approach called Schema Therapy (ST), that integrates theory and techniques from psychodynamic and emotion focused therapy, holds the promise to fill this gap in cognitive literature. In this model, psychopathology is viewed as the interaction between the innate temperament of the child and the early experiences of deprivation or frustration of the subject's basic needs. This deprivation may lead to develop early maladaptive schemas (EMS), and maladaptive Modes. In the present paper we point out that EMSs and Modes are associated with either dysregulated emotions or with dysregulatory strategies that produce and maintain problematic

							emotional responses. Thanks to a special focus on the therapeutic relationship and emotion focused-experiential techniques, this approach successfully treats severe emotional dysregulation. In this paper, we make several comparisons between the main ideas of ST and the science of emotion regulation, and we present how to conceptualize pathological phenomena in terms of failed regulation and some of the ST strategies and techniques to foster successful regulation in patients.
Dahl, Hanne-Sofie Johnsen; Høglend, Per; Ulberg, Randi; Amlo, Svein; Gabbard, Glen O.; Perry, John Christopher; Christoph, Paul Crits	2017	Does Therapists' Disengaged Feelings Influence the Effect of Transference Work? A Study on Countertransference	Couns and Psychother Res (Counselling and Psychotherapy Research)	24	2	462-474	Exploration of the patient-therapist relationship (transference work) is considered a core active ingredient in dynamic psychotherapy. However, there are contradictory findings as for whom and under what circumstances these interventions are beneficial. This study investigates long-term effects of transference work in the context of patients' quality of object relations (QOR) and therapists' self-reported disengaged feelings. Therapists' disengaged feelings may negatively influence the therapeutic process, especially while working explicitly with the transference since discussing feelings that are present in the session is an essential aspect of transference work. One hundred outpatients seeking psychotherapy for depression, anxiety and personality disorders were randomly assigned to one year of dynamic psychotherapy with transference work or to the same type and duration of treatment, but without transference work. Patients' QOR-lifelong pattern was evaluated before treatment and therapists' feelings were assessed using the Feeling Word Checklist-58 after each session. Outcome was measured with self-reports and interviews at pre-treatment, mid-treatment, post-treatment, one year and three years after treatment termination. A significant interaction of treatment group (transference

						<p>work versus no transference work) by QOR by disengaged therapist feelings was present, indicating that disengaged feelings, even small amounts, were associated with negative long-term effects of transference work, depending on QOR Scale scores. The strengths of the negative association increased significantly with lower levels of QOR. The negative association between even a small increase in disengaged therapist feelings and long-term effects of transference interpretation was substantial for patients with poor QOR, but small among patients with good QOR. Copyright ? 2016 John Wiley & Sons, Ltd. Key Practitioner Message Therapists' emotional reactions to their patients (countertransference) seem to have a significant impact on both the treatment process and outcome of psychotherapy. Therapists' heightened level of disengaged feelings over a treatment period shows an adverse impact on the effect of transference work for all patients, and especially so for patients with a history of poor, non-mutual and complicated relationships. For patients with a history of reciprocal, sound relationships the negative influence of therapists' disengaged countertransference is minimal. Higher therapist disengagement is strongly related to inferior therapists' skill for patients with a history of poor relationships and/or more personality disorder pathology. Training and supervision should provide direct feedback and focus on therapists' internal thought processes and emotional reactions. Therapists need to recognize and understand their feelings and attitudes in order to use the countertransference as a tool to understand the interpersonal process in therapy.</p>

Dahling, V.; May, S.; Peter, S. V.; Schwarz, J.; Ignatyev, Y.; Scheibner, H.; Heinze, M.	2022	Expectations of patients and relatives for modern hospital care in geriatric psychiatry	Zeitschrift fur Gerontologie und Geriatrie	55	6	476–481	OBJECTIVE: In order to improve health care in geriatric psychiatry, users must be granted a larger role in shaping their treatment. To this aim we identify factors that are essential to psychiatric care from users' perspectives. METHODS: Focus groups and interviews (n = 12) were conducted to identify the health care factors that were most essential to its users. In addition, patients (n = 72) and relatives (n = 62) evaluated the current health care in a questionnaire. RESULTS: The most essential factors were longer consultations with doctors and treatment providers, comprehensive and comprehensible information, individualized procedures and therapies, having clearly defined scopes for each professional group, environmental factors and the integration of relatives into the therapy process. CONCLUSION: The reported factors could help improve health services in geriatric psychiatry by pointing towards potential changes and room for optimization in health care on both structural and process levels.
D'Amico, Ferdinando; Magro, Fernando; Caron, Benedicte; Dignass, Axel; Jairath, Vipul; Hart, Ailsa; Kotze, Paulo Gustavo; Paridaens, Kristine; Awadhi, Sameer	2023	iSTART-II: An Update on the i Support Therapy-Access to Rapid Treatment (iSTART) Approach for Patient-Centered Therapy in Mild-to-Moderate Ulcerative Colitis	Journal of clinical medicine	12	3		The i Support Therapy-Access to Rapid Treatment (iSTART) was an initiative to improve patient-centered management in mild-to-moderate ulcerative colitis (UC). Our aim was to update the iSTART recommendations in order to include fecal calprotectin (FC) in the monitoring of patients with UC and improve their management. Twelve physicians from nine countries worldwide attended a virtual international consensus meeting on 4 May 2022. Data from three systematic reviews were analyzed, and a new systematic review investigating all studies reporting measurement of FC at home was conducted. Based on literature evidence, statements were formulated, discussed, and approved by voting. Statements were considered approved if at least 75% of

Al; Kobayashi, Taku; Siegmund, Britta; Peyrin-Biroulet, Laurent; Danese, Silvio							participants agreed with a proposed statement. Fourteen statements were approved. Based on this consensus, FC measurement should be routinely performed for monitoring patients with mild-to-moderate UC to identify disease relapses early and initiate an appropriate treatment. Further studies are needed to assess whether self-monitoring of FC is associated with better disease control and improved patients' quality of life.
Danböck, Sarah K.; Liedlgruber, Michael; Franke, Laila K.; Miedl, Stephan F.; Hettegger, Sabrina E.; Weber, Rainer-Christian; Wilhelm, Frank H.	2024	Acute dissociation as part of the defense cascade: Associations with behavioral, autonomic, and experiential threat responses in posttraumatic stress disorder	Journal of Psychopathology and Clinical Science	133	1	76–89	Dissociative symptoms, such as depersonalization and derealization, are experienced by about half of individuals with posttraumatic stress disorder (PTSD). Theoretical models propose that acute dissociation is accompanied by specific behavioral, physiological, and experiential alterations and contributes to unfavorable PTSD symptom course. Yet, empirical evidence is scarce. Here, we explored associations between dissociative and behavioral, physiological, and experiential threat responses as well as effects of dissociative responding on PTSD symptom course. Individuals with PTSD (N = 71) participated in a preregistered script-driven imagery study including exposure to standardized, detail-enriched trauma, and neutral scripts. Stabilometry, eye-tracking, facial electromyography, autonomic psychophysiology, and self-report data were collected. Moreover, PTSD symptoms were assessed before and 3 months after testing. Analyses did not link acute dissociation to bodily and facial immobility or staring in response to trauma scripts. However, dissociation displayed an inverted U-shaped relationship with heart rate and was linked to higher nonspecific skin conductance fluctuation and higher high-frequency heart rate variability in response to trauma scripts. Moreover, acute dissociation was linked to higher self-reported negative affect responses to

							<p>trauma scripts and displayed a U-shaped relationship with unfavorable PTSD symptom course. While results did not confirm hypothesized behavioral markers of dissociation, they do support defense-cascade model assumptions of an inverted U-shaped relationship between dissociation and psychophysiological arousal resulting from a progression of parasympathetic versus sympathetic dominance with increasing dissociation. On an experiential level, results did not confirm posttraumatic dissociation-induced emotional numbing, questioning theoretical notions. The observed nonlinear associations may help explain the heterogeneity of prior findings and might inform an updated conceptualization of posttraumatic dissociation. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
<p>Danese, Silvio; Banerjee, Rupa; Cummings, Fraser [JR]; Dotan, Iris; Kotze, Paulo G.; Leong, Rupert Wing Loong; Paridaens, Kristine; Peyrin-Biroulet, Laurent; Scott, Glyn; van Assche, Gert; Wehkamp, Jan; Yamamoto-Furusho, Jesús K.</p>	2018	<p>Consensus recommendations for patient-centered therapy in mild-to-moderate ulcerative colitis: the iSupport Therapy-Access to Rapid Treatment (iSTART) approach</p>	<p>Intestinal research</p>	16	4	522–528	<p>Symptomatic ulcerative colitis (UC) can be a chronic, disabling condition. Flares in disease activity are associated with many of the negative impacts of mild-to-moderate UC. Rapid resolution of flares can provide benefits to patients and healthcare systems. iSupport Therapy-Access to Rapid Treatment (iSTART) introduces patient-centered care for mild-to-moderate UC. iSTART provides patients with the ability to self-assess symptomology and self-start a short course of second-line treatment when necessary. An international panel of experts produced consensus statements and recommendations. These were informed by evidence from systematic reviews on the epidemiology, mesalazine (5-ASA) treatment, and patient use criteria for second-line therapy in UC. Optimized 5-ASA is the first-line treatment in all clinical guidelines, but may not be sufficient to induce remission in all patients. Corticosteroids should be prescribed as second-line therapy when needed, with</p>

							budesonide MMX® being a preferred steroid option. Active involvement of suitable patients in management of UC flares has the potential to improve therapy, with patients able to show good accuracy for flare self-assessment using validated tools. There is a place in the UC treatment pathway for an approach such as iSTART, which has the potential to provide patient, clinical and economic benefits.
Danner, Dennis	2016	JA zu mir!. Trauma und seelisches Wachstum					Aus einer personenzentrierten Haltung heraus werden die Erkenntnisse der Traumaforschung für das Konzept einer integrativen Psychotherapie und für die Förderung von Persönlichkeitsentwicklung nutzbar gemacht. Durch das Prinzip des Bejahens und Beachtens wird die Förderung seelischen Wachstums ermöglicht. Bejahter Widerstand ist dabei das Potential eines jeden bei der Verarbeitung von Traumata. Unbewusster Widerstand wird als zerstörerische Kraft gesehen, die die Aufspaltung der Traumastruktur begünstigt. Es werden Grundprinzipien beschrieben, wie mit Widerstand umgegangen werden kann, um von Zerstörung zu Bejahung zu gelangen. - Inhalt: (1) Was ist ein Trauma. (2) Ein Modell zur Traumaanalyse. (3) Traumatische Situation. (4) Bindungstrauma. (5) erlebnismuster. (6) Krise. (7) Zusammenfassung. (8) Niederlagen als Chance. (9) Stabilisieren oder Schritte. (10) Selbstbeachten als Weg. (11) Therapeutische Schritte. (12) Bejahende Arbeit mit dem Widerstand. (13) Innere Autorität.
Darcy, Alison M.; Fitzpatrick, Kara K.; Lock, James	2016	Cognitive remediation therapy and cognitive behavioral therapy with an	Psychotherapy	53	2	232-240	Cognitive remediation therapy represents a new approach to the treatment of anorexia nervosa (AN) emerging from research, suggesting that adults with chronic AN have specific neurocognitive inefficiencies. Specifically, adults with AN demonstrate an overly detailed cognitive processing bias (Roberts, Tchanturia, &

		older adult with anorexia nervosa: A brief case report					Treasure, 2013) and difficulties shifting set quickly and efficiently (Roberts, Tchanturia, Stahl, Southgate, & Treasure, 2007). These characteristics manifest as rigid, rule-bound, and detail-focused cognitions, beliefs, and behaviors. Versions of these problems appear to persist after weight restoration (Tchanturia et al., 2004) and are observable in patient's healthy sisters (Roberts et al., 2013). Thus, central coherence difficulties and set-shifting problems have been proposed as endophenotypes and maintaining factors of AN (Roberts et al., 2013). Daszkowski, Alexandra	2021	Wenn Gefhle Farben formen: Kunsttherapie und emotionsfokussierte Psychotherapie	Musik-, Tanz- und Kunsttherapie	31	2	212-225	Emotionsfokussierte Psychotherapie ist ein evidenzgesttztes Verfahren, das Emotionen fr die Funktionalitt eines Menschen und seinen therapeutischen Vernderungsprozess als zentral erachtet. Der Beitrag befasst sich mit der Rolle von Kunsttherapie in der emotionsfokussierten psychiatrisch-psychotherapeutischen Behandlung. berschneidungsbereiche zwischen emotionsfokussierter Psychotherapie und Kunsttherapie werden aufgezeigt und mit Erfahrungen aus der Praxis belegt. Ein Fallbeispiel zeigt, wie auf Bilderebene im Laufe eines kunsttherapeutischen Prozesses verschiedene authentische Gefhlsqualitten und Ressourcen sichtbar sowie besprechbar wurden und in einer Bilderreihe sinnhaft miteinander verbunden werden konnten. Aus dem integrativen Ansatz und dem vielversprechenden Verlauf ergibt sich die Empfehlung, spezifische emotionsfokussierte Kunsttherapie in das multiprofessionell ausgerichtete psychotherapeutische Behandlungskonzept, welches auf eine frderliche

							Modifikation problematischer Gefühle abzielt, einzubeziehen.
Datta, Nandini; Matheson, Brittany; Walker, Avery Carter; van Wye, Eliza; Lock, James D.	2023	Psychoeducational and motivational treatment for low-weight Avoidant/Restrictive Food Intake Disorder (ARFID): Three case reports in school-aged children	Clinical child psychology and psychiatry	28	3	1123–1134	BACKGROUND: Individuals with Avoidant/Restrictive Food Intake Disorder (ARFID) experience restrictive or highly selective eating problems that interfere with growth and development. Despite the increasing number of referrals for ARFID, no evidence-based treatments exist. This compilation of case composites describes a novel manualized treatment, Psychoeducational and Motivational Treatment (PMT) for children with ARFID, focusing on exploring motivation to change eating behaviors. This approach is based on motivational non-directive psychotherapy models, psychoeducational interventions, and the usefulness of play to support psychotherapeutic learning in school-age children. CASE PRESENTATIONS: Three cases of children with ARFID treated using PMT are presented: a 7-year-old, a 10-year-old, and a 12-year-old. These cases illustrate how a clinician delivers PMT interventions in the context of developmental abilities and common comorbidities associated with ARFID. CONCLUSION: PMT is a promising therapy for ARFID in school-age children. Challenges and strategies are discussed, including ways to address obstacles such as young age, comorbidities, and use of the virtual environment.
Davis, Sean D.; Hsieh, Alexander L.	2019	What Does it Mean to be a Common Factors Informed Family Therapist?	Family process	58	3	629–640	The common factors paradigm in couple and family therapy has gained popularity over the past several decades, leading many therapists to refer to themselves as common factors family therapists. Despite this, no consensus exists on what it means to be a common factors family therapist, or if such a designation even makes sense given that the common factors paradigm is not a model. Synthesizing the existing common factors

							literature, a case is made for the designation "common factors informed family therapist," and the following six core principles are outlined that characterize this designation: (1) sees overlap among theories; (2) passionate about theory, not a theory; (3) client centered; (4) monitors hope and the therapeutic alliance; (5) views clients as people rather than objects; and (6) prioritizes healing over therapy. Each of the concepts is discussed in depth, and clinical implications are provided.
de Almeida Sampaio, Thiago Pacheco; Jorge, René Cabral; Martins, Daniel Santos; Gandarela, Lucas Marques; Hayes-Skelton, Sarah; Bernik, Márcio Antonini; Lotufo-Neto, Francisco	2020	Efficacy of an acceptance-based group behavioral therapy for generalized anxiety disorder	Depression and anxiety	37	12	1179–1193	BACKGROUND: Generalized anxiety disorder (GAD) shows the weakest treatment response among anxiety disorders. This study aimed at examining whether an acceptance-based group behavioral therapy (ABBT) for patients in a Brazilian anxiety disorders program, combining mindfulness and exposure strategies, can improve clinical outcome when compared with a standard nondirective supportive group therapy (NDST). METHODS: Ninety-two individuals diagnosed with GAD were randomized to receive 10 sessions of either ABBT or NDST. Assessments at pretreatment, midtreatment, posttreatment, and 3-month follow-up comprised the following outcome measures: Hamilton Anxiety Rating Scale (HAM-A), Penn State Worry Questionnaire (PSWQ), Depression Anxiety and Stress Scale (DASS), and the Clinical Global Impressions (CGI). The World Health Organization Quality of Life (WHOQOL) was administered at pretreatment and posttreatment. RESULTS: The mixed-effects regression models for DASS-stress, Hamilton Anxiety Interview, and CGI showed a significant effect for Time and the Time × Treatment effect, but not for the Treatment main effect. Similarly, there was a significant Time × Treatment effect for the PSWQ, but not main effects of Time or Treatment. Altogether, these data

							indicate that symptoms decreased in both conditions across treatment and follow-up, and that the rate of change was more rapid for those participants in the ABBT condition. We found no differences between groups from pretreatment to posttreatment in DASS-anxiety or any secondary outcome measure, but for the physical health domain of WHOQOL, which was faster in ABBT. CONCLUSIONS: Both groups showed good clinical outcomes, but in general, participants of the ABBT group improved faster than those in the NDST group.
Dean, Suzanne; Tonge, Bruce; Beaufoy, Jeanette; Godfrey, Celia; Grady, Jacqueline; Pullen, Jill; Smale, Sarina; Hill, Christine; Ivey, Gavin; Taffe, John	2023	The Melbourne Study of Psychoanalytic Psychotherapy low-cost clinic I: Implementation , mental health and life functioning gains	Appl Psychoanal Studies (International Journal of Applied Psychoanalytic Studies)	20	4	551-572	
Decelis, Karen; Falzon, Ruth	2022	I cannot do that...I'm a counsellor: Implications of professional boundaries on counsellors' public life as entertainers	Couns and Psychother Res (Counselling and Psychotherapy Research)	22	2	480-490	
DeCou, Christopher R.;	2017	Assault-related shame	Psychological Trauma: Theory,	9	2	166-172	[Correction Notice: An Erratum for this article was reported in Vol 10(2) of Psychological Trauma: Theory,

<p>Cole, Trevor T.; Lynch, Shannon M.; Wong, Maria M.; Matthews, Kathleen C.</p>	<p>mediates the association between negative social reactions to disclosure of sexual assault and psychological distress</p>	<p>Research, Practice, and Policy</p>			<p>Research, Practice, and Policy (see record 2018-08774-001). In the article, there was an error in the coding of missing values thus effecting the abstract, Methods, Results, and Discussion sections. The frequency counts for sexual assault victimization, reactions to social disclosure, and assault-related shame were calculated incorrectly due to an error in the coding of missing values, and have been corrected in the description of participants and in the results and discussion sections. In addition, the sample size was incorrectly reported as N = 207, and should have appeared as “N = 208.” The sample size and corresponding percentages have been corrected throughout the text. Two transcription errors for the indirect effects via PTSD and global distress were also corrected. These indirect effects were incorrectly reported as “PCL-C; $\beta = .27$,” and “OQ-45.2; $\beta = .21$,” and should have appeared as “PCL-C; $\beta = .26$,” and “OQ-45.2; $\beta = .20$.”] Objective: Several studies have identified associations between social reactions to disclosure of sexual assault and psychological distress; however, no studies have evaluated shame as a mediator of this association. This study evaluated assault-related shame as a mediator of the associations between negative social reactions to disclosure of sexual assault and symptoms of posttraumatic stress disorder (PTSD), depression, and global distress and hypothesized that there would be an indirect effect of social reactions to disclosure upon symptoms of psychopathology via assault-related shame. Method: Participants were 207 female psychology undergraduates who reported past history of completed or attempted sexual assault and had disclosed the assault to at least 1 other person. Participants completed self-report measures of social reactions to sexual assault</p>
--	--	---------------------------------------	--	--	---

						disclosure, assault-related shame, and symptoms of psychopathology. Results: Participants reported significant histories of attempted or completed sexual assault and indicated clinically significant symptoms of depression and subthreshold symptoms of PTSD and global distress, on average. Evaluation of structural models confirmed the hypothesized indirect effect of negative social reactions to sexual assault disclosure upon symptoms of PTSD ($z = 5.85, p < .001$), depression ($z = 4.56, p < .001$), and global distress ($z = 4.82, p < .001$) via assault-related shame. Conclusions: These findings offer new insight concerning the intervening role of assault-related shame and highlight the importance of shame as a target for therapeutic intervention. This study suggests the need for future research concerning the role of shame in the etiology of PTSD and process of disclosure among survivors of attempted or completed sexual assault. DeDios-Stern, Samantha; Lee, Eun-Jeong		Blame, coping, and psychosocial outcomes in caregivers of individuals with brain injury	Rehabilitation Psychology	62	3	Objective: Acquired brain injury (ABI) is associated with many physical and psychiatric conditions. Oftentimes, the individual's family members are responsible for providing long-term care, leaving caregivers vulnerable to negative effects of caregiving including stress, depression, and decreased quality of life. Attribution theory suggests that caregivers may blame the individual with the ABI for their injury as a way to understand their own circumstances. The objective of this study was to investigate caregiver coping strategies as possible mediators between caregiver family member blame and caregiver psychosocial outcomes among caregivers of individuals with ABI. Method: Caregivers of individuals with ABI ($n = 94$) completed an online survey of self-report

							measures regarding coping (emotion-focused, problem-focused, and dysfunctional strategies), blame (direct, indirect, and preoccupation with blame), depressive symptoms, and quality of life (QOL). Bootstrapping mediation analyses were conducted to investigate the mediating role of caregiver coping strategies between blame attributions, and either depressive symptoms or QOL. Results: Results demonstrated that the use of more dysfunctional coping strategies significantly mediated the relationship between indirect blame, and depressive symptoms and QOL. Furthermore, using more dysfunctional coping strategies also significantly mediated the relationship between preoccupation with blame and depressive symptoms. Conclusions: Results of this study point to the important role blame attributions play in the use of coping strategies and subsequent psychosocial outcomes. By understanding the relationships between blame attributions, coping behavior, and psychosocial outcomes, clinicians may better tailor treatments to optimize QOL and promote the psychological well being of caregivers and care recipients. Deemer, Ashley D.; Massof, Robert W.; Rovner, Barry W.; Casten, Robin J.; Piersol, Catherine V.	2017	Functional Outcomes of the Low Vision Depression Prevention Trial in Age-Related Macular Degeneration	Investigative ophthalmology & visual science	58	3	1514–1520	PURPOSE: To compare the efficacy of behavioral activation (BA) plus low vision rehabilitation with an occupational therapist (OT-LVR) with supportive therapy (ST) on visual function in patients with age-related macular degeneration (AMD). METHODS: Single-masked, attention-controlled, randomized clinical trial with AMD patients with subsyndromal depressive symptoms (n = 188). All subjects had two outpatient low vision rehabilitation optometry visits, then were randomized to in-home BA + OT-LVR or ST. Behavioral activation is a

						structured behavioral treatment aiming to increase adaptive behaviors and achieve valued goals. Supportive therapy is a nondirective, psychological treatment that provides emotional support and controls for attention. Functional vision was assessed with the activity inventory (AI) in which participants rate the difficulty level of goals and corresponding tasks. Participants were assessed at baseline and 4 months. RESULTS: Improvements in functional vision measures were seen in both the BA + OT-LVR and ST groups at the goal level ($d = 0.71$; $d = 0.56$ respectively). At the task level, BA + OT-LVR patients showed more improvement in reading, inside-the-home tasks and outside-the-home tasks, when compared to ST patients. The greatest effects were seen in the BA + OT-LVR group in subjects with a visual acuity $\geq 20/70$ ($d = 0.360$ reading; $d = 0.500$ inside the home; $d = 0.468$ outside the home). CONCLUSIONS: Based on the trends of the AI data, we suggest that BA + OT-LVR services, provided by an OT in the patient's home following conventional low vision optometry services, are more effective than conventional optometric low vision services alone for those with mild visual impairment. (ClinicalTrials.gov number, NCT00769015.).
Deepeshwar, Singh; Nagendra, H. R.; Rana, Bal Budhi; Visweswaraiyah, Naveen Kalkuni	2019	Evolution from four mental states to the highest state of consciousness: A neurophysiological basis of meditation as	Progress in brain research	244	31–83	This chapter provides a theoretical introduction to states of consciousness and reviews neuroscientific investigations of meditation. The different states of consciousness consist of four mental states, i.e., cancalata (random thinking), ekagrata (non-meditative focusing), dharna (focused meditation), and dhyana (meditation) as defined in yoga texts. Meditation is a self-regulated mental process associated with deep relaxation and increased internalized attention. Scientific investigations on meditation reported changes in

		defined in yoga texts					<p>electrophysiological signals and neuroimaging measures. But most outcomes of meditation studies showed inconsistent results, this may be due to heterogeneity in meditation methods and techniques evolved in the last 200 years. Traditionally, the features of meditation include the capacity to sustain a heightened awareness of thoughts, behaviors, emotions, and perceptions. Generally, meditation involves non-reactive effortless monitoring of the content of experience from moment to moment. Focused meditation practice involves awareness on a single object and open monitoring meditation is a non-directive meditation involved attention in breathing, mantra, or sound. Therefore, results of few empirical studies of advanced meditators or beginners remain tentative. This is an attempt to compile the meditation-related changes in electrophysiological and neuroimaging processes among experienced and novice practitioners.</p>
Degerli, Yusuf Islam; Dogu, Feridun; Oksuz, Cigdem	2022	Manufacturing an assistive device with 3D printing technology - a case report	Assistive technology : the official journal of RESNA	34	1	121-125	<p>Our aim is to define the design and procedure of a 3D printed assistive device and to produce a prototype assistive device for an individual with quadriplegia in order to enable him/her to independently conduct daily living activities. For the design and production of the 3D assistive device, we followed six steps. In the first step-determination of problematic activity/client-centered approach-writing activity was determined as the most problematic activity as a result of the interview with a paraplegic patient. Then, 2D drawings of the assistive device were created as the second step. For the third step the 3D scan of the individual's right hand was obtained. 3D scan of the right hand was transferred to CATIA program and the 3D printer is used in the manufacturing process for the fourth step. In the fifth step, we produced</p>

							a low-cost novel writing assistive device. The writing device was introduced to the disabled individual and training was given regarding its practical use in the final step teaching the use of the device. As 3D printing technology progresses and becomes more reliable, we believe that the production of assistive devices will become much easier and their use will become more prevalent.
Del Carmen Espinoza, María	2020	The use of collaborative/therapeutic assessment with oppositional defiant disorder: A longitudinal case study	Rorschachiana	41	2	200–222	The aim of the present single case study was to demonstrate the effectiveness of a therapeutic evaluation model (CTA) used for 4 years with a teenage girl (13–17 years of age) with oppositional defiant disorder (ODD). Clinical evaluations using autobiography as well as the Millon Adolescent Clinic Inventory, House–Tree–Person Drawing, and Rorschach test (Comprehensive System) were conducted at each of four time points: 13, 14, 15, and 17 years of age. An average of four evaluation sessions were carried out at each time point following feedback of the results to the client, reflections about her experience with the evaluation process and with results obtained were requested in writing. Progressive findings reveal a gradual decrease in ODD markers and increasing sophistication, organization, and realism in the configuration of the drawings. The Rorschach test gradually indicated a decrease in aggression content and improvement in the quality of responses. In conclusion, the longitudinal design used in the case shows a strengthening of the self, a notable decrease in oppositional defiant behavior, and an adaptation and adjustment to reality as expected for a young woman of the client's age. Deleo, Andrea; Romero, Roberta; Zelaya, Enmanuelle A.	2021	Movimiento Ventana: An Alternative Proposal to Mental Health in Nicaragua				295–311	<p>This chapter describes the experience of Movimiento Ventana as a self-managed social movement and the use of arts-based alternative therapies—Biodanza and Art Therapy—in a group non-directive methodology under an approach of recovery and restitution of rights in the Psychosocial Hospital of Managua, Nicaragua. These therapies and approaches seek to promote health, positively influence the recovery of mental health users and reduce the social stigma associated with mental health. Biodanza and Art Therapy have proven to be effective techniques when working with people living with mental disorders, generating benefits at both the individual and social levels and developing areas where hegemonic therapies are limiting. As well, the use of art as a transformative tool fosters social participation and a more active role of participants in the activities. At the same time, it influences volunteers, transforming what is understood by “madness” and “being crazy” and recognizing the importance of mental health. Finally, it is recognized the need to question our own stigmas and roles of power in order to create more horizontal spaces where human rights, freedom, and the autonomy of people living with mental disorders are ensured and respected.</p>
Delgadillo, Jaime; Gonzalez Salas Duhne, Paulina		Targeted prescription of cognitive–behavioral therapy versus person-centered counseling for depression	Journal of consulting and clinical psychology	88	1		<p>Objective: Depression is a highly common mental disorder and a major cause of disability worldwide. Several psychological interventions are available, but there is a lack of evidence to decide which treatment works best for whom. This study aimed to identify subgroups of patients who respond differentially to cognitive–behavioral therapy (CBT) or person-centered counseling for depression (CfD). Method: This was a retrospective analysis of archival routine practice data for</p>

		using a machine learning approach					1,435 patients who received either CBT (N = 1,104) or CfD (N = 331) in primary care. The main outcome was posttreatment reliable and clinically significant improvement (RCSI) in the PHQ-9 depression measure. A targeted prescription algorithm was developed in a training sample (N = 1,085) using a supervised machine learning approach (elastic net with optimal scaling). The clinical utility of the algorithm was examined in a statistically independent test sample (N = 350) using chi-square analysis and odds ratios. Results: Cases in the test sample that received their model-indicated "optimal" treatment had a significantly higher RCSI rate (62.5%) compared to those who received the "suboptimal" treatment (41.7%); $\chi^2(df = 1) = 4.79, p = .03, OR = 2.33$ (95% CI [1.09, 5.02]). Conclusion: Targeted prescription has the potential to make best use of currently available evidence-based treatments, improving outcomes for patients at no additional cost to psychological services. Demir, Sati; Ercan, Feride	2022	The effectiveness of cognitive behavioral therapy-based group counseling on depressive symptomatology, anxiety levels, automatic thoughts, and coping ways Turkish nursing students: A randomized controlled trial	Perspectives in psychiatric care	58	4	2394–2406	<p>PURPOSE This study aimed to evaluate the effectiveness of cognitive behavioral therapy (CBT)-based group counseling focused on depressive symptoms, anxiety levels, automatic thoughts, and coping ways among undergraduate nursing students with mild to moderate depressive symptoms.</p> <p>DESIGN AND METHODS A randomized, nonblinded, controlled trial was conducted. The study was completed with a total of 63 participants (n = 31, intervention group; n = 32, control group). The effect of the intervention was evaluated with Beck depression inventory, Beck anxiety inventory, automatic thoughts questionnaire, and ways of coping questionnaire. The measurements were taken three times: pretest, posttest, and 2-months posttest.</p> <p>FINDINGS CBT-based group counseling was found to reduce depressive symptoms, automatic thoughts, and ineffective coping with stress and to increase effective coping with stress. In both groups, 2-months posttest mean anxiety score was lower than the pre-test mean score.</p> <p>PRACTICE IMPLICATIONS CBT-based group counseling reduced depressive symptoms, automatic thoughts, and emotion-focused/ineffective ways for coping with stress.</p>
Demir, Selin; Schwarz,	2022	Therapy from my point of view: A case	Journal of clinical psychology	78	10	2029–2040	Lately, the use of patient-reported outcome measures (PROM) to adapt and improve ongoing psychotherapeutic treatments has become more widespread. Their main

Franziska; Kaiser, Tim		illustration of routine outcome monitoring and feedback in psychotherapeutic interventions					purpose is to support data-informed, collaborative treatment decisions which include the patient's point of view on their progress. In case of nonresponse or deterioration, these systems are able to warn clinicians and guide the process "back on track" in treatment. In this case illustration, the Greifswald Psychotherapy Navigator System (GPNS) detected the deterioration of 19-year-old Sarah during the first eight sessions of cognitive-behavioral therapy for social anxiety and depression. Here, the GPNS helped the therapist gain insight as to how Sarah's social anxiety affected their treatment and adjust her strategy accordingly. Using the symptom curves and progress scales of the GPNS, the therapist was able to then address her patient's struggles in detail during their sessions and with her supervisor. After adapting her therapeutic approach, the patient's deterioration could be averted while simultaneously strengthening their communication in the process. Clinical implications and the benefits of using PROM systems for evidence-based personalization of psychotherapy are presented.
Demisch, Anja Maja; Kuchinke, Lars	2022	Do the relationships between age and the personality of psychotherapists differ from expected trajectories? A cross-sectional study	Couns and Psychother Res (Counselling and Psychotherapy Research)	22	4	970-981	Abstract Objectives Large-scale panel data suggest that older people tend to be less neurotic, extraverted and open-minded, but more agreeable and conscientious. In this study, the relationships between age and the Big Five dimensions were examined for 324 German psychotherapists. Methods A model uncertainty and robustness approach was applied to evaluate the stability of relationships between age and the Big Five measures across a multiverse of regression analyses when controlling for job experience, gender, psychotherapeutic orientation, and occupational demands. Results Older psychotherapists were found to be more open and less

							neurotic, and conscientious. Relationships were found to be linear and were not moderated by occupational demands. Conclusions The observed relationships between age and psychotherapists' personality are discussed in consideration of social investment theories and a close connection between personal and professional development as a distinct feature of psychotherapeutic work. Those patterns parallel clients' preferences and likely contribute to therapy outcomes, which should be addressed in future studies in psychotherapy research.
Dempewolf, Eva; Fink, Birgit	2021	Wie gut die Wahrheit tut. Rogers' drei Sulen in der Kommunikation zu Coronazeiten - Und darber hinaus	Gesprchspsych ootherapie und Personzentrierte Beratung	52	1	28-30	In der personzentrierten Ausbildung werden die drei Sulen des Ansatzes von Carl Rogers vermittelt: wertschtzende Akzeptanz, Kongruenz (oder Authentizitt) und Empathie. Seit vielen Jahren arbeiten die Autorinnen nicht nur auf dieser Basis mit Klienten und Patienten, die drei Sulen sind auch zu einer Grundhaltung geworden, die ihre eigene Kommunikation bestimmt - im beruflichen Kontext wie im privaten Bereich. Jetzt - mitten im Lockdown - gewinnt diese Haltung eine neue Dimension. Denn alle Betroffene und haben hnliche Gefhle: Sorgen, Angst, Wut, Hilflosigkeit. Diese Last wird getragen, egal, mit wem kommuniziert wird. Die Last ist allgegenwrtig und damit immer im Weg. Tatschlich? Die Autorinnen beschftigt, dass Rogers' Thesen gerade in diesen sonderbaren Zeiten besonders hilfreich sein knnen, und wie verzwick es sein kann, diese zur Zeit selbst zu leben.
Dennis, Cindy-Lee E.	2004	Treatment of postpartum depression, part 2: a critical review of	The Journal of clinical psychiatry	65	9	1252-1265	BACKGROUND While postpartum depression is a common mental condition with significant burden, it often remains undiagnosed and untreated. The objective of this article is to critically review the literature to determine the current state of scientific knowledge related to the treatment of

		nonbiological interventions				<p>postpartum depression from a nonbiological perspective.</p> <p>DATA SOURCES Databases searched for this review included MEDLINE, PubMed, CINAHL, PsycINFO, EMBASE, ProQuest, the Cochrane Library, and the WHO Reproductive Health Library from 1966 to 2003. The search terms used were postpartum/postnatal depression and randomized controlled/clinical trials. Published peer-reviewed articles in English from 1990 to 2003 were included in the review, although select earlier studies were also included based on good methodological quality and/or the absence of more recent work.</p> <p>METHOD The criteria used to evaluate the interventions were based on the standardized methodology developed by the U.S. Preventive Services Task Force and the Canadian Task Force on Preventive Health Care.</p> <p>RESULTS Twenty-one studies that met inclusion criteria were examined. These studies included interpersonal psychotherapy, cognitive-behavioral therapy, peer and partner support, nondirective counseling, relaxation/massage therapy, infant sleep interventions, infant-mother relationship therapy, and maternal exercise. Although some of these interventions have been better studied for depression unrelated to childbirth, methodological limitations render their efficacy equivocal for postpartum depression.</p> <p>CONCLUSIONS Definite conclusions cannot be reached about the relative effectiveness of most of the nonbiological treatment approaches due to the lack of well-designed investigations. Randomized controlled trials are needed</p>
--	--	-----------------------------	--	--	--	---

							to compare different treatment modalities, examine the effectiveness of individual treatment components, and determine which treatments are most useful for women with different risk factors or clinical presentations of postpartum depression.
Depp, Colin A.; Parrish, Emma M.; Chalker, Samantha A.; Ehret, Blaire C.; Kamarsu, Snigdha; Perivoliotis, Dimitri; Granholm, Eric	2023	Pilot feasibility trial of a brief mobile-augmented suicide prevention intervention for serious mental illness	Psychiatric Rehabilitation Journal	46	1		Objective: People with serious mental illnesses (SMIs) are at high risk for suicidal ideation and behavior, and yet few suicide prevention interventions have been customized for this group. We describe the outcomes of a pilot trial of Mobile SafeTy And Recovery Therapy (mSTART), a four-session suicide-focused cognitive behavioral intervention for SMI, designed for the transition from acute to outpatient care and augmented with ecological momentary intervention to reinforce intervention content. Methods: The primary objective of this pilot trial was to evaluate the feasibility, acceptability, and preliminary effectiveness of START. Seventy-eight people with SMI and elevated suicidal ideation were randomized to either: (a) mSTART or (b) START alone (i.e., without mobile augmentation). Participants were evaluated at baseline, 4 weeks (end of in-person sessions), 12 weeks (end of mobile intervention), and 24 weeks. The primary outcome of the study was change in suicidal ideation severity. Secondary outcomes included psychiatric symptoms, coping self-efficacy, and hopelessness. Results: A total of 27% of randomized persons were lost to follow-up after baseline, and engagement with mobile augmentation was variable. There was clinically significant improvement ($d = 0.86$) in suicidal ideation severity scores sustained over 24 weeks, with similar effects seen for secondary outcomes. Preliminary comparison indicated a medium effect size ($d = 0.48$) advantage at 24 weeks of mobile augmentation in suicidal ideation severity scores.

							Treatment credibility and satisfaction scores were high. Conclusions and Implications for Practice: START, regardless of mobile augmentation, was associated with sustained improvement in suicidal ideation severity and secondary outcomes in people with SMI at-risk for suicide in this pilot trial. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Deres-Cohen, Keren; Dolev-Amit, Tohar; Peysachov, Galit; Ramseyer, Fabian T.; Zilcha-Mano, Sigal	2021	Nonverbal synchrony as a marker of alliance ruptures	Psychotherapy	58	4	499–509	Findings from the past 5 decades of empirical research on the working alliance suggest its importance in psychotherapy. Recent studies have sought to identify markers of the alliance, of which one of the most promising candidates is nonverbal synchrony. Delving into processes that constitute the alliance, such as alliance ruptures, may shed light on underlying mechanisms of the association between nonverbal synchrony and the therapeutic relationship. The present study examines whether nonverbal synchrony can serve as a marker of alliance ruptures. To achieve this aim, 418 sessions of 75 therapeutic dyads were coded for ruptures, using the Rupture Resolution Rating System, and for nonverbal synchrony, using motion energy analysis. A mixed-method analysis, integrating multilevel nested models with a case study analysis, was implemented. The results of the multilevel nested models suggest that nonverbal synchrony is significantly associated with confrontational ruptures, whereas withdrawal ruptures showed no such association. The findings of the case analysis suggest that moments of especially high nonverbal synchrony during a rupture are those in which the therapist made great efforts to be attentive to the patient when the patient acted in a confrontational manner. The findings of the present study demonstrate the potential of nonverbal synchrony to

							serve as a marker of confrontational ruptures. The findings support the social glue assumption, according to which therapists may seek higher levels of nonverbal synchrony with patients to maintain a strong alliance in the face of difficulties. Desai, Raj; Sonawane, Kalyani	2019	Depression treatment use among stroke individuals with depression: A cross-sectional analysis of the Medical Expenditure Panel Survey	Research in social & administrative pharmacy : RSAP	15	11	1338–1343	BACKGROUND: Depression is the most prevalent psychiatric comorbidity among stroke individuals. Despite the effectiveness of antidepressants and psychotherapy, data on the use of these treatments among stroke survivors is limited. OBJECTIVE: The main objective of this study was to document prevalence of antidepressant use, types of antidepressants utilized, and adherence to antidepressants among stroke individuals. METHODS: Retrospective, cross-sectional data obtained from the Medical Expenditure Panel Surveys (MEPS), for the years 2011, 2013 and 2015, was utilized for this study. Treatment for depression was categorized into three mutually exclusive categories: 1) antidepressants only, 2) antidepressants and psychotherapy (combination), and 3) No treatment. Adherence to antidepressants was measured using the Proportion of Days Covered (PDC) ratio. Adherence between antidepressant only and combination therapy group was compared using Student's t-test. A multinomial logistic regression analysis was used to further examine the association between patient characteristics and likelihood of receiving depression treatment. RESULTS: A total of 759 stroke individuals with comorbid depression were identified. Of these, 51.2% utilized only antidepressants, 12.6% utilized a combination treatment of antidepressants and psychotherapy and 31.7% did not receive treatment for depression. Selective Serotonin

							<p>Reuptake Inhibitors (SSRI's) was the most commonly used antidepressants in the stroke population. Males (P = 0.04), age group of 40-64 years (P < 0.001), and African Americans (P = 0.02) constituted for the highest proportions of untreated stroke survivors. Among treated stroke individuals, adherence was higher for combination therapy users compared to those using antidepressants only (mean PDC = 65.8 ± 6.89 and 57.6 ± 3.74, respectively). CONCLUSION: Almost 70% of stroke individuals received some form of treatment for depression and several patient-related factors (gender, age, race, marital status, and comorbidity burden) were associated with the utilization of depression treatment. Future researchers need to investigate the factors responsible for lack of depression treatment in stroke individuals and policy makers should aim for a more patient centered care.</p>
Dettke, Monika	2018	Die personenzentrierte Beratung von Multiple-Sklerose-Kranken und Angehörigen	Gesprächspsychotherapie und Personenzentrierte Beratung	49	3	159-160	<p>Vorgestellt wird das Projekt "Betroffene beraten Betroffene" der Deutschen Multiple Sklerose Gesellschaft (DMSG). Angesprochen werden Inhalte der Ausbildung, die sich an den Prinzipien der personenzentrierten Beratung und dem Peer Counseling orientiert, sowie Herausforderungen in der praktischen Tätigkeit der Laienberater und -beraterinnen.</p>
Di Malta, Gina; Oddli, Hanne W.; Cooper, Mick	2019	From intention to action: A mixed methods study of clients' experiences of goal-oriented practices	Journal of clinical psychology	75	10	1770-1789	<p>OBJECTIVES Goal-oriented practices are central to many contemporary psychotherapies. The aim of this study was to explore clients' experiences of this work.</p> <p>DESIGN Mixed methods, with a main qualitative part and a smaller quantitative component. Participants were 22 clients in integrative psychotherapy (15 females, 6 males, 1 "other"). Semistructured interviews after session 4 and at</p>

							<p>endpoint were analyzed thematically. On the basis of the identified themes, "goal attitude" scores were developed and their correlations with outcomes investigated.</p> <p>RESULTS</p> <p>Goal-oriented practices could help clients move from intention to action through increased awareness and focus, setting manageable tasks, and progress monitoring. However, they had the potential to hinder clients' awareness of their intentions, feel irrelevant, disorientating, or demotivating. Effectiveness hinged on client's management of their expectations, flexible working, and time. Positive attitudes toward goal-oriented practices were associated with improvement.</p> <p>CONCLUSIONS</p> <p>Goal-oriented practices can enhance psychotherapeutic work but need to be individually tailored and implemented collaboratively.</p>
Diamond, Gary M.; Boruchovitz-Zamir, Rotem; Nir-Gotlieb, Ofir; Gat, Inbal; Bar-Kalifa, Eran; Fitoussi, Priel-Yehoshua; Katz, Shira	2022	Attachment-based family therapy for sexual and gender minority young adults and their nonaccepting parents	Family process	61	2	530–548	<p>This pilot open trial examined the efficacy of attachment-based family therapy (ABFT) for Israeli sexual and gender minority (SGM) young adults and their persistently nonaccepting parents. Thirty families received up to 26 weeks of treatment, with parental rejection, parental acceptance, and young adults' attachment avoidance and attachment anxiety assessed at baseline, 8, 16, 24, and 36 weeks (three months post-treatment). Analyses using multilevel growth models revealed that both young adults and their mothers independently reported increases in mothers' acceptance of their young adult's same-sex orientation or noncisgender identity. In addition, young adults reported decreases in both parents' levels of rejection. Also, mothers, but not fathers, reported decreases in their own level of rejection. Finally, young adults reported a decrease in attachment</p>

							<p>avoidance in their relationships with both mothers and fathers, but not a decrease in attachment anxiety. Importantly, these treatment gains were maintained three months after the end of treatment. Together, these results suggest that ABFT-SGM, a manualized, affirmative, experiential, family-based treatment, may be effective in reducing long-standing parental rejection, promoting parental acceptance, and improving the quality of LGBTQ+ young adults' relationships with their parents. These findings are encouraging in light of the urgent need for efficacious interventions to reduce family generated minority stress and promote safer, more supportive environments for sexual and gender minority people.</p>
Diamond, Gary M.; Shahar, Ben; Sabo, Daphna; Tsvieli, Noa	2016	Attachment-based family therapy and emotion-focused therapy for unresolved anger: The role of productive emotional processing	Psychotherapy	53	1	34–44	<p>A growing body of research suggests that emotional processing is a central and common change mechanism across various types of therapies (Diener & Hilsenroth, 2009; Foa, Huppert, & Cahill, 2006; Greenberg, 2011). This study examined whether 10 weeks of attachment-based family therapy (ABFT), characterized by the use of in-session young adult–parent dialogues, were more effective than 10 weeks of individual emotion-focused therapy (EFT), characterized by the use of imaginal dialogues, in terms of facilitating productive emotional processing among a sample of 32 young adults presenting with unresolved anger toward a parent. This study also examined whether greater amounts of productive emotional processing predicted more favorable treatment outcomes. In contrast to our expectations, we found significantly more productive emotional processing in individual EFT than in conjoint ABFT. Results also showed that while both treatments led to significant and equivalent decreases in unresolved anger, state anger, attachment anxiety, and psychological</p>

							symptoms, only ABFT was associated with decreases in attachment avoidance. Although amount of emotional processing did not explain the unique decrease in attachment avoidance in ABFT, greater amounts of productive emotional processing predicted greater decreases in psychological symptoms (but not other outcome measures) across both treatments. Diamond, Guy S.; Kobak, R. Roger; Krauthamer Ewing, E. Stephanie; Levy, Suzanne A.; Herres, Joanna L.; Russon, Jody M.; Gallop, Robert J.	2019	A Randomized Controlled Trial: Attachment-Based Family and Nondirective Supportive Treatments for Youth Who Are Suicidal	Journal of the American Academy of Child and Adolescent Psychiatry	58	7	721-731	<p>OBJECTIVE: To evaluate the efficacy of attachment-based family therapy (ABFT) compared with a family-enhanced nondirective supportive therapy (FE-NST) for decreasing adolescents' suicide ideation and depressive symptoms. METHOD: A randomized controlled trial of 129 adolescents who are suicidal ages 12- to 18-years-old (49% were African American) were randomized to ABFT (n = 66) or FE-NST (n = 63) for 16 weeks of treatment. Assessments occurred at baseline and 4, 8, 12, and 16 weeks. Trajectory of change and clinical recovery were calculated for suicidal ideation and depressive symptoms. RESULTS: There was no significant between-group difference in the rate of change in self-reported ideation (Suicidal Ideation Questionnaire-Jr; $F(1,127) = 181, p = .18$). Similar results were found for depressive symptoms. However, adolescents receiving ABFT showed a significant decrease in suicide ideation ($t(127) = 12.61, p < .0001$; effect size, $d = 2.24$). Adolescents receiving FE-NST showed a similar significant decrease ($t(127) = 10.88, p < .0001$; effect size, $d = 1.93$). Response rates (ie, $\geq 50\%$ decrease in suicide ideation symptoms from baseline) at post-treatment were 69.1% for ABFT versus 62.3% for FE-NST. CONCLUSION: Contrary to expectations, ABFT did not perform better than FE-NST. The 2 treatments produced substantial decreases in suicidal ideation and</p>

							depressive symptoms that were comparable to or better than those reported in other more intensive, multicomponent treatments. The equivalent outcomes could be attributed to common treatment elements, different active mechanisms, or regression to the mean. Future studies will explore long-term follow up, secondary outcomes, and potential moderators and mediators. CLINICAL TRIAL REGISTRATION INFORMATION: Attachment-Based Family Therapy for Suicidal Adolescents; http://clinicaltrials.gov ; NCT01537419.
Dichter, Martin Nikolaus; Quasdorf, Tina; Schwab, Christian Günter Georg; Trutschel, Diana; Haastert, Burkhard; Riesner, Christine; Bartholomeyczi k, Sabine; Halek, Margareta	2015	Dementia care mapping: effects on residents' quality of life and challenging behavior in German nursing homes. A quasi-experimental trial	International psychogeriatrics	27	11	1875–1892	BACKGROUND Person-centered care (PCC) is a widely recognized concept in dementia research and care. Dementia Care Mapping (DCM) is a method for implementing PCC. Prior studies have yielded heterogeneous results regarding the effectiveness of DCM for people with dementia (PwD). We aimed to investigate the effectiveness of DCM with regard to quality of life (QoL) and challenging behavior in PwD in nursing homes (NHs). METHODS Leben-QD II is an 18-month, three-armed, pragmatic quasi-experimental trial. The sample of PwD was divided into three groups with three living units per group: (A) DCM applied since 2009, (B) DCM newly introduced during the study, and (C) a control intervention based on a regular and standardized QoL rating. The primary outcome was QoL measured with the Quality of Life-Alzheimer's Disease (QoL-AD) proxy, and the secondary outcomes were QoL (measured with QUALIDEM) and challenging behavior (measured with the Neuropsychiatric Inventory Nursing Home version, NPI-NH). RESULTS

							<p>There were no significant differences either between the DCM intervention groups and the control group or between the two DCM intervention groups regarding changes in the primary or secondary outcomes. At baseline, the estimated least square means of the QoL-AD proxy for groups A, B, and C were 32.54 (confidence interval, hereafter CI: 29.36-35.72), 33.62 (CI: 30.55-36.68), and 30.50 (CI: 27.47-33.52), respectively. The DCM groups A (31.32; CI: 28.15-34.48) and B (27.60; CI: 24.51-30.69) exhibited a reduction in QoL values, whereas group C exhibited an increase (32.54; CI: 29.44-35.64) after T2.</p> <p>CONCLUSIONS</p> <p>DCM exhibited no statistically significant effect in terms of QoL and challenging behavior of PwD in NHs. To increase the likelihood of a positive effect for PwD, it is necessary to ensure successful implementation of the intervention.</p>
DiCorcia, Marina; Iwakabe, Shigeru; Thoma, Nathan C.; Yamazaki, Wakako	2023	Transformational process scale: An initial validation and application to the first psychotherapy session	Journal of Psychotherapy Integration	33	3	248-264	<p>In order to understand the process of emotional transformation in psychotherapy, the development of objective measures of patient emotional processing that capture clinically important aspects of the patient affective state is crucial. The Transformational Process Scale (TPS) is an observer-based measure of patient emotional processing based on the phenomenology of transformation in Accelerated Experiential Dynamic Psychotherapy (AEDP) that captures the process of emotional change in four sequential phases of distinct affective experiences. TPS categorizes 1-min segments of therapy sessions into one of the four states and also notes the intensity of the emotion experienced on a 5-point Likert scale. One of its unique features is that it categorizes different classes of positive emotions. This</p>

							paper details the TPS and its empirical utility. First, the theoretical background of the scale is described. Second, an initial validation study is presented. Third, the scale is illustrated with clinical vignettes representing each state of TPS. As an initial validation of the TPS scale, a subset of sessions was scored by two raters. A satisfactory level of interrater reliability at the level of the four major affective categories and their intensity was demonstrated. The TPS ratings showed that productive first sessions involved higher frequency and intensity of classes of positive emotions. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Dictado, Jermaine; Torres-Harding, Susan R.	2023	Predictors of therapy trainees' pathologizing and invalidating microaggressions with sexual and racial minority therapy clients	Training and Education in Professional Psychology		19 31-39 26(Electronic), 19 31-39 18(Print)	304-313	Providing culturally affirmative clinical care entails taking care not to engage in therapy microaggressions nor invalidate the client's own experiences of microaggressions. The present study aimed to understand if therapy trainees enact microaggressions of overpathologization and invalidation toward racial and/or sexual orientation minority clients and to understand whether factors such as countertransference, perceived multicultural competence, empathy, heterosexism, and colorblindness contributed to the likelihood of enacting those microaggressions. One hundred and ten participants were randomly assigned to read one of four clinical vignettes of a client who reported experiencing discrimination because of her identity. Conditions differed by client race (White or African American) and sexual orientation (heterosexual or lesbian). Participants did not overpathologize racial and sexual minority clients. However, participants who reported greater overwhelmed/disorganized countertransference and greater colorblindness were more likely to overpathologize their clients. Participants invalidated the

							<p>microaggression experiences of the White heterosexual client the most when compared to the other conditions. Additionally, participants who reported experiencing overwhelmed/disorganized countertransference reactions and more colorblindness were less likely to believe the client's experiences of microaggressions, whereas having greater helpless/inadequate countertransference and positive countertransference was associated with being more likely to believe the client. Results suggest that therapy training programs might facilitate therapy trainees' engagement in self-reflection around countertransference reactions and help students minimize colorblindness so that trainees will better acknowledge and sensitively address clients' experiences with microaggressions. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Diepeveen, Sanne; van Haaften, Leenke; Terband, Hayo; Swart, Bert de; Maassen, Ben	2020	Clinical Reasoning for Speech Sound Disorders: Diagnosis and Intervention in Speech-Language Pathologists' Daily Practice	American journal of speech-language pathology	29	3	1529–1549	<p>Purpose This study aims to give an insight in clinical reasoning (diagnosis and intervention) of speech-language pathologists (SLPs) in the Netherlands for children with speech sound disorder (SSD). Method The study featured a mixed-method (qualitative and quantitative) design. Semistructured interviews containing nondirective, open-ended questions were conducted with 33 SLPs, which were analyzed using a constant comparative analysis. Other SLPs (137) filled out a questionnaire on the same topics. Multiple-choice questions were analyzed by descriptive frequencies, while open-ended questions were analyzed thematically. Results The results indicate that SLPs use a variety of assessments to diagnose SSD, complemented by observation and, often, case history. In total, 85 different diagnostic labels were reported. The choice of intervention is based on what is appealing to the child</p>

							and what matches his or her age as well as on the specific diagnosis and severity. Interventions are used for multiple speech disorders, and according to SLPs, parents play a large role in diagnostics and intervention. Conclusion These results reveal the need for (a) a clear and consistent terminology of diagnoses in the field of pediatric SSD, (b) a fast and easy-to-administer comprehensive differential diagnostic instrument in combination with an instrument to assess participation in everyday life, and (c) a tool to conduct a case history online.
Diepholz, Annerieke; Mensing, Heidi	2017	Psychosoziale Beratung in Familien mit chronisch kranken Kindern	Gesprächspsychotherapie und Personenzentrierte Beratung	48	1	35–39	Grundlagen der psychosozialen Beratung in Familien mit chronisch kranken Kindern werden erörtert. Anhand von Erfahrungen aus dem Projekt KOMPASS, einem psychologischen Beratungsangebot für betroffene Familien, werden Beratungsbedürfnisse im Kontext einer chronischen Erkrankung dargestellt. Dabei wird ein Blick auf den Umgang mit chronischer Erkrankung, die Gestaltung des Familienalltags und die Krankheitsbewältigung geworfen. Vor diesem Hintergrund werden Ziele der Beratung skizziert.
Dillon, Andrew; Timulak, Ladislav; Greenberg, Leslie S.	2018	Transforming core emotional pain in a course of emotion-focused therapy for depression: A case study	Psychotherapy research: journal of the Society for Psychotherapy Research	28	3	406–422	To investigate the pattern of change in emotional states over a course of emotion-focused therapy using the model of sequential emotional processing as an initial framework for analysis. This was a single case study observational design examining 15 sessions of therapy with one client. A qualitative analysis of moment-to-moment shifts in client emotional events was conducted. This conceptualised the interplay between experienced emotions using the sequential emotional processing model as an interpretative framework. The analysis was triangulated by using existing observer-based rating scales and reliability assessed with an independent rater.

							<p>The sequential emotional processing model was found to be an effective means to explain the sequence of expressed emotional events, although some emotional events and emotion scheme change processes pertaining to this particular case required additional explanation than provided in the original model descriptions. Observed nuances in this specific case included highlighting triggers to emotional experience and avoidance processes fuelled by anticipatory fear. The observations included a process of change through accessing core feelings of shame, fear, and loneliness and their transformation through the generation of self-compassion and assertive anger. Implications for practice are discussed in terms of case conceptualisation and therapeutic strategy.</p>
Diltsch, Ulla	2018	Gruppenarbeit in der Integrativen Gestalttherapie. Theoretische Grundlagen und Perspektiven für die Praxis					<p>Es wird eine Übersicht über theoretische Grundlagen und Aspekte geboten, die zu einem fachspezifischen Verständnis von Gruppen und Gruppenprozessen in der integrativen Gestalttherapie beitragen. Zunächst werden der geschichtliche Hintergrund und der Entwicklungskontext in Bezug auf Gruppenarbeit und Gruppentherapie in der integrativen Gestalttherapie dargestellt und danach wird der aktuelle Forschungsstand skizziert. Relevante sozialpsychologische und gruppendynamische Grundlagen werden fokussiert beschrieben. Perspektiven für die Praxis ergänzen die theoretischen Ausführungen. Den Abschluss bildet eine Auseinandersetzung mit folgender Frage: Was braucht eine Gruppe, um eine Gruppe zu werden - was unterstützt Einzelne dabei, das Risiko von Kontakt in einer Gruppe einzugehen?</p>
DiMauro, Jennifer;	2019	PTSD and relationship	Psychological Trauma: Theory,	11	5	534–541	<p>Objective: Intimate relationships are critical to posttrauma functioning and recovery. The vast majority of</p>

Renshaw, Keith D.		satisfaction in female survivors of sexual assault	Research, Practice, and Policy				research focusing on PTSD and relationship functioning has focused exclusively on male combat veterans, from whom female sexual assault survivors may differ in critical ways. This study investigates the strength of the association between PTSD symptoms and relationship satisfaction, as well as the role of three interpersonal processes (sexuality, communication, and hostility) in female sexual assault survivors. Method: Data was collected from female survivors of sexual assault in romantic relationships via online survey. Results: PTSD symptom severity and relationship satisfaction were not significantly correlated. The direct effect of PTSD symptom severity on relationship satisfaction was positive, whereas indirect effects through negative communication, positive communication, and sexual satisfaction were all significantly negative, as expected. Finally, the correlation of PTSD symptom severity with relationship satisfaction differed depending on whether or not participants were in treatment. Results suggest that for those not in treatment, greater PTSD symptoms are associated with poorer relationship satisfaction. Conclusions: Preliminary evidence suggests that communication and sexual satisfaction may be particularly salient issues for sexual assault survivors' posttrauma psychopathological and relationship functioning, but participation in treatment may be associated with reduced impact of PTSD symptoms on interpersonal functioning. Dinić, Bojana M.; Sadiković, Selka; Wertag, Anja	2021	Factor mixture analysis of the Dark Triad and Dark Tetrad:	Journal of Individual Differences	42	2	74–83	The aim of this research was to examine the structure of the Dark Triad and Tetrad traits by answering the question whether a person-centered or a variable-centered approach is more suitable for their description, or its

		Could sadism make a difference?					combination. Moreover, we examined whether the inclusion of sadism into the dark traits constellation would change the results. On a sample of 404 participants, both short and full-length measures of the Dark Triad were used, while sadism was assessed via Short Sadistic Impulse Scale. The results of the factor mixture analysis showed that the variable-centered approach is better at describing the Dark Triad, but the inclusion of sadism resulted in qualitatively different latent profiles, suggesting that the person-centered approach could serve in describing the Dark Tetrad. Inclusion of sadism led to the isolation of higher Dark Tetrad-sadism profile in both short and full-length measures and this profile showed the higher risk behaviors and interpersonal problems. Other isolated profiles could be interpreted as lower and higher Dark Tetrad profiles, with some specificities. Results showed that inclusion of sadism contributed to the isolation of profile more prone to sadism, but also to isolation of other profiles, suggesting that it could change the relations among dark traits. Dinkel, Andreas	2018	Psychotherapeutische Anstze zur Behandlung von Progredienzangst bei Patienten mit einer Krebserkrankung	Verhaltenstherapie und Verhaltensmedizin	39	2	198–210	Progredienzangst (PA) bezeichnet die Angst vor dem Fortschreiten oder dem Wiederauftreten einer körperlichen Erkrankung und den damit verbundenen Folgen. Auch wenn PA als eine prinzipiell angemessene, zu erwartende Reaktion auf die reale Bedrohung durch eine Krebserkrankung anzusehen ist, kann sie ein Ausmaß erreichen, das klinisch bedeutsam und behandlungswürdig ist. Im vorliegenden Beitrag wird ein Überblick über die wichtigsten vorliegenden Therapieansätze gegeben. Es zeigt sich, dass neben kognitiv-verhaltenstherapeutischen Interventionen auch

							<p>zahlreiche weitere Anstze zum Einsatz kamen, so zum Beispiel Metakognitive Therapie, Supportiv-Erfahrungsorientierte Therapie, Dankbarkeitsorientierte Intervention oder Achtsamkeitsbasierte Stressreduktion. Es liegen gruppen- und einzeltherapeutische Anstze sowie telefonuntersttze und Online-Interventionen vor. Die Mehrzahl der Therapiestudien belegte eine Abnahme der PA in den Interventionsgruppen. Somit ist festzuhalten, dass PA einer psychotherapeutischen Reduktion zugnglich ist, wobei verschiedene psychotherapeutische Anstze erfolgversprechend zu sein scheinen.</p>
DiPerna, James Clyde; Lei, Puiwa; Cheng, Weiyi; Hart, Susan Crandall; Bellinger, Jillian	2018	A cluster randomized trial of the Social Skills Improvement System-Classwide Intervention Program (SSIS-CIP) in first grade	Journal of Educational Psychology	110	1	1-16	<p>The purpose of this study was to evaluate the efficacy of a universal social skills program, the Social Skills Improvement System Classwide Intervention Program (SSIS-CIP; Elliott & Gresham, 2007), for students in first grade. Classrooms from 6 elementary schools were randomly assigned to treatment or business-as-usual control conditions. Teachers assigned to the treatment condition implemented the SSIS-CIP over a 12-week period. Students' social skills, problem behaviors, and approaches to learning were assessed via teacher ratings and direct observations of classroom behavior. In addition, their early literacy and numeracy skills were measured via computer-adaptive standardized tests. SSIS-CIP participation yielded small positive effects in students' social skills (particularly empathy and social engagement) and approaches to learning (academic motivation and engagement). Students' problem behaviors and academic skills, however, were unaffected by SSIS-CIP exposure. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>

<p>Ditlefsen, Ingrid Tande; Nissen-Lie, Helene Amundsen; Andenæs, Agnes; Normann-Eide, Eivind; Johansen, Merete Selsbak; Kvarstein, Elfrida Hartveit</p>	<p>2021</p>	<p>“Yes, there is actually hope!”—A qualitative investigation of how patients experience mentalization-based psychoeducation tailored for borderline personality disorder</p>	<p>Journal of Psychotherapy Integration</p>	<p>31</p>	<p>3</p>	<p>257–276</p>	<p>Common factors, such as the working alliance, positive expectations, and psychoeducation have been robustly related to outcome in studies of psychotherapy. As a multicomponent treatment for borderline personality disorder (BPD), Mentalization-based treatment (MBT) includes introductory group-based psychoeducation on core features of personality functioning, BPD, the treatment program and disorder-related personal management. Generally, few studies have investigated patients’ views on how psychoeducation works. This study aimed to explore their experience of the group-based psychoeducation. Twelve patients who had attended the introductory group-based psychoeducation in MBT participated. Qualitative interviews were analyzed using Interpretative Phenomenological Analysis. MBT psychoeducation was found helpful in itself and in the further treatment process. Identified experiences related to the group (feeling less ashamed, learning from others, feeling different from others), acquisition of “tools” for better personal management (the psychoeducational content; putting new knowledge into practice), preparation for longer term therapy (therapy became more trustworthy, easier to understand, felt more effective), and demanding aspects (problems with attendance or concentration). This qualitative study is the first to present patients’ own experiences of psychoeducation as part of MBT and suggests that psychoeducation is a powerful and facilitating intervention. Careful patient selection may further optimize its potential. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>

Ditye, Thomas; Rodax, Natalie; Welleschik, Lisa	2023	Alexinomia: The fear of using personal names	Frontiers in psychology	14		1129272	INTRODUCTION: Preliminary research based on everyday observations suggests that there are people, who experience severe fear when addressing others with their personal names. The aim of this study was to explore the extent to which this hitherto little-known psychological phenomenon really exists and to investigate its characteristic features, considering the everyday experience of not being able to use names and its impact on affected individuals and their social interactions and relationships. METHODS: In this mixed-methods study based on semi-structured interviews and psychometric testing, 13 affected female participants were interviewed and evaluated using self-report measures of social anxiety, attachment-related vulnerability, and general personality traits. An inductive content analysis and inferential statistical methods were used to analyze qualitative and quantitative data, respectively. RESULTS: Our findings show that affected individuals experience psychological distress and a variety of negative emotions in situations in which addressing others with their name is intended, resulting in avoidance behavior, impaired social interactions, and a reduced quality of affected relationships. DISCUSSION: The behavior can affect all relationships and all forms of communication and is strongly linked to social anxiety and insecure attachment. We propose calling this phenomenon Alexinomia, meaning "no words for names".
Dmitryeva, Nadezhda; Chernov, Nikita; Kostyuk, Georgiy; Lysaker, Paul H.	2021	Utilizing MERIT to promote recovery in schizotypal personality disorder: An	Journal of clinical psychology	77	8	1798– 1806	Abstract Introduction Difficulties forming an integrated sense of oneself, others, and one's place in the community have been observed to pose a barrier to recovery from schizophrenia spectrum disorders (SSD). This has promoted the development of metacognitive approaches to psychotherapy that seek to assist persons

		illustrative case study					in making sense of and managing their psychosocial challenges. One of these approaches, Metacognitive Reflection Insight Therapy (MERIT), has begun to be more broadly explored among adults with schizophrenia. Persons with other forms of SSD, including schizotypal personality disorder (SPD), also experience difficulties forming an integrated sense of themselves and others and could potentially be amenable to MERIT. Methods To explore this possibility, this study reports the application of MERIT to an adult with SPD in a unique cultural context. Results Evidence of acceptability and meaningful resultant clinical gains are described. Conclusions Taken as a whole, this study provides a rich illustration of how metacognition can be successfully targeted by MERIT in forms of SSD potentially less severe than schizophrenia, including SPD in a unique cultural setting.
Dockweiler, Christoph; Kupitz, Anna; Hornberg, Claudia	2018	Acceptance of Online-based Therapy by Patients with Light to Moderate Depressive Disorders	Gesundheitswesen (Bundesverband der Ärzte des Öffentlichen Gesundheitsdienstes (Germany))	80	11	1013–1022	OBJECTIVES: Over the past few years, there has been a considerable increase in online-based therapeutic services for people affected by depressive disorders. The efficacy and efficiency of these programmes is well documented by now. User acceptance is considered as a significant factor of success in establishing this new patient-centered care. Theory-based acceptance surveys can provide valuable scientific knowledge regarding long-term introduction. METHODS: A nationwide online survey was conducted to determine the attitude towards web-based psychotherapy services for depressive disorders, the current state of knowledge and the intention of 186 participants (124 female and 62 male participants; aged 21 and above) to use these services. The participants were recruited from support groups for depressive disorders. The determinants of the intention to use online therapy, which is included in the binary logistic

							<p>regression, are based upon the Unified Theory of Acceptance and Use of Technology (UTAUT). RESULTS: Nearly two-thirds of the respondents could conceive making use of online-based therapeutic services in the near future. The perceived performance and expected effort proved to be significantly influential predictors regarding the intention to use. Specifically, these included an evaluation of the use of E-Mental Health to assist disease management, and better assessment of the course of one's disease. CONCLUSION: The actual contribution of E-Mental Health is closely connected to technical and jurisprudential assessments. But also, it significantly depends on evidence-based issues as well as user orientation in research, development and implementation. The results offer an initial theory-based approach to an increased user-oriented technology research in health care, with further diversity criteria to be taken into account in the future.</p>
Documet, P. I.; Macia, L.; Boyzo, R.; Thompson, A. F.; Amruthapuri, R.	2020	Outcomes from a Male-to-Male Promotores Intervention in an Emerging Latino Community	Journal of immigrant and minority health	22	4	717–726	<p>Emerging Latino communities experience social isolation and lack services tailored to their culture. Few male-to-male promotores (community health workers in Spanish) interventions exist. This 6-month participatory study aimed to improve social support, healthcare access, depressive symptoms, and decrease alcohol consumption among Latino immigrant men. Promotores delivered non-directive social support to participants recruited from community venues. We analyzed baseline and 6-month questionnaires data (n = 89) using paired chi square tests. All participants were immigrants; 47% had not finished high school, 29% had depression symptoms, 35% reported past month binge drinking and 93% were uninsured. The intervention significantly improved having a usual source of care (24 to 43%), doctor's visits (41 to</p>

							62%) and dentist's visits (27 to 42%) in the past year. Other outcomes did not improve. Male promotores increased healthcare access among vulnerable Latino men. Addressing drinking behavior and depression may require longer interventions or specialized providers.
Dohm, Lea; Niessen, Pia; van Bronswijk, Katharina	2020	"Was hast du damals dagegen getan?" - Psychotherapeutische Perspektiven auf die Klimakrise. Ein Beitrag der Bewegung "Psychologists/ Psychotherapists for Future"	Gesprächspsychotherapie und Personenzentrierte Beratung	51	4	6-8	ohne Abstract
Dolan, Megan; Jin, Ling; Sharma, Rachita; Weiss, Nicole H.; Contractor, Ateka A.		The relationship between number of trauma types, resilience, and psychological symptoms in ex-military personnel from India	Psychological Trauma: Theory, Research, Practice, and Policy	14	3		Objective: Traumatic event (TE) types have been shown to relate to adverse psychological outcomes. However, research in this area has relied almost exclusively on linear analysis and has been limited to Western countries with similar cultural values. Addressing these limitations, this study examined (a) presence and nature of relations between number of TE types and psychological outcomes and (b) minimum number of TE types predicting psychological symptoms in a culturally distinct sample of ex-military members from India. Method: The sample of 144 trauma-exposed Indian ex-military members (M _{age} = 43.49; 90.90% males) completed a web-based survey. Results: Curvilinear regression analyses indicated quadratic relationships between number of TE types and psychological symptoms (posttraumatic stress disorder

							<p>[PTSD], depression, and anxiety severity) and resilience. Exploratory analyses showed (a) linear relationships between number of directly experienced TE types and psychological outcomes, (b) quadratic relationships between number of Predominant Death Threat TEs and psychological symptoms, (c) linear relationship between number of Predominant Death Threat TEs and resilience, and (d) linear relationships between other TE categories and psychological outcomes. Nonparametric receiver operating characteristic curve analyses indicated that a threshold of at least 10.5 TE types provided the optimal balance between sensitivity and specificity in classifying participants with (vs. without) probable PTSD, depression, and generalized anxiety disorder. For those reporting directly experienced TE types, this threshold was 2.5–3.5 TE types. Conclusion: Study results enhance an understanding of psychological difficulties faced by Indian ex-military members who have experienced multiple TE types, which can inform psychotherapeutic treatments for this population. Dolev-Amit, Tohar; Eubanks, Catherine F.; Zilcha-Mano, Sigal	2021	A moderating factor for patients with vindictive interpersonal problems	Psychotherapy	58	3	343–352	<p>Individuals high in vindictive interpersonal problems tend to experience and express anger and irritability. In treatment, they have poor prognosis for alliance and outcome. We propose that positive expectation may serve as a moderating factor for these patients. In the current study, we examined the ability of expected alliance to act as a moderating factor in the early process and early progress of treatment for patients with vindictive interpersonal problems. A sample of 65 patients received short-term dynamic psychotherapy. At intake, before meeting the therapist, participants completed assessments for vindictive interpersonal</p>

						<p>problems and expected alliance. All therapy sessions were videotaped, and Session 2 was coded for confrontation ruptures. Early progress was assessed using the improvement from intake to Week 2 in the measure of distress from interpersonal relations. Our results show that, at high levels of vindictive interpersonal problems, higher expected alliance was associated with fewer confrontation ruptures. At high levels of vindictive interpersonal problems, higher expected alliance was associated with greater early improvement in distress from interpersonal relations. The findings demonstrate how positive expectations may function as a moderating factor that enables patients with vindictive tendencies to achieve a positive process and progress early in treatment. <p>Doll, Gayle A.; Cornelison, Laci J.; Rath, Heath; Syme, Maggie L.</p>	<p>2017</p>	<p>Actualizing culture change: The Promoting Excellent Alternatives in Kansas Nursing Homes (PEAK 2.0) program</p>	<p>Psychological Services</p>	<p>14</p>	<p>3</p>	<p>Nursing homes have been challenged in their attempts to achieve deep, organizational change (i.e., culture change) aimed at providing quality of care and quality of life for nursing home residents through person-centered care. To attain deep change, 2 well-defined components must be in place: a shared understanding of (a) the what, or content goals, and (b) the how, or process of change. However, there are few examples of this at a macro or micro level in long-term care. In an effort to enact true culture change in nursing homes statewide, the Kansas Department for Aging and Disability Services implemented the Promoting Excellent Alternatives in Kansas Nursing Homes program. This program is a Medicaid, pay-for-performance program that formalizes the content and process of achieving culture change through person-centered care principles. This article aims to detail the content (what) and process (how) of a</p>

							model macro-level program of culture change throughout the State of Kansas. Applications to the micro level (individual homes) are presented, and implications for psychologists' roles in facilitating culture change are discussed. (PsycINFO Database Record (c) 2017 APA, all rights reserved)
Dollberg, Daphna G.; Behrendt, Hadar; Shorer, Maayan; Bamberger, Esther	2023	Integrative parent psychotherapy: Using the cyclical psychodynamic s approach	Journal of Psychotherapy Integration	33	4	422-438	This article explores the ways in which the cyclical psychodynamics framework can be applied to parent psychotherapy to ameliorate a child's symptomatology. It is argued that working therapeutically with parents calls for an integrative approach that uses multiple concepts and different intervention modalities to address the bidirectional interplay between the intrapersonal sphere of the parent, the intrapersonal sphere of the child, and the interpersonal parent-child interactions, where the behavioral and relational spheres of both are expressed. Using this framework can serve to conceptualize how the child's symptoms emerged and are maintained and to identify points and ways in which change can occur. A case study of a child with encopresis is discussed. We show how creating a case formulation and conceptualizing the vicious and virtuous cycles in the parent-child relationship can contribute to forming an alliance with the parents, setting treatment goals, planning interventions, and eventually improving the child's symptoms and well-being. Then, a clinical vignette illustrates the integrative use of mentalization-based, cognitive-behavioral, and emotion-focused treatment strategies. We discuss how they each contribute to changes in intrapsychic and interpersonal patterns in the parents and the child. Finally, we discuss the merits and limitations of this therapeutic approach and suggest

							directions for future exploration and research. (PsycInfo Database Record (c) 2024 APA, all rights reserved)
Domhardt, Matthias; Baumeister, Harald	2018	Psychotherapy of adjustment disorders: Current state and future directions	World Journal of Biological Psychiatry, 2018				Objectives: This narrative review article provides an overview of current psychotherapeutic approaches specific for adjustment disorders (ADs) and outlines future directions for theoretically-based treatments for this common mental disorder within a framework of stepped care. Methods: Studies on psychological interventions for ADs were retrieved by using an electronic database search within PubMed and PsycINFO, as well as by scanning the reference lists of relevant articles and previous reviews. Results: The evidence base for psychotherapies specifically targeting the symptoms of AD is currently rather weak, but is evolving given several ongoing trials. Psychological interventions range from self-help approaches, relaxation techniques, e-mental-health interventions, behavioural activation to talking therapies such as psychodynamic and cognitive behavioural therapy. Conclusions: The innovations in DSM-5 and upcoming ICD-11, conceptualising AD as a stress-response syndrome, will hopefully stimulate more research in regard to specific psychotherapeutic interventions for AD. Low intensive psychological interventions such as e-mental-health interventions for ADs may be a promising approach to address the high mental health care needs associated with AD and the limited mental health care resources in most countries around the world.

Dong, Lu; Lee, Jason Y.; Harvey, Allison G.	Memory support strategies and bundles: A pathway to improving cognitive therapy for depression?	Journal of consulting and clinical psychology	85	3	<p>[Correction Notice: An Erratum for this article was reported in Vol 85(12) of Journal of Consulting and Clinical Psychology (see record 2017-53491-004). In the article, there was an error in Table 2 of the Results. In Table 2, the MS summary scores of the Total amount of MS are missing six descriptive statistics. They should have read as: 13.50, 8.54, 23, 18.32, 8.83, 23. The corrected table is included.] Objective: Therapist use of memory support (MS) alongside treatment-as-usual, with the goal of enhancing patient recall of treatment contents, has been of recent interest as a novel pathway to improve treatment outcome. The memory support intervention (MSI) involves treatment providers' using 8 specific MS strategies to promote patient memory for treatment. The present study examines to what extent therapist use of MS strategies and bundles improves patient recall of treatment contents and treatment outcome. Method: The data were drawn from a pilot RCT reported elsewhere. Participants were 48 adults (mean age = 44.27 years, 29 females) with major depressive disorder (MDD), randomized to receive 14 sessions of either CT + Memory Support (n = 25) or CT-as-usual (n = 23). Therapist use of MS was coded using the Memory Support Rating Scale. Patient memory and treatment outcomes were assessed at baseline, midtreatment (patient recall only), posttreatment, and 6-month follow-up. Results: Participants in CT + Memory Support received significantly higher amount of MS relative to CT-as-usual. Although not reaching statistical significance, small-to-medium effects were observed between MS strategies and patient recall in the expected direction. Although MS variables were not significantly associated with changes in continuous depressive symptoms, MS</p>
---	---	---	----	---	---

							was associated with better global functioning. MS also exhibited small to medium effects on treatment response and recurrence in the expected direction but not on remission, though these effects did not reach statistical significance. Conclusions: These results provide initial empirical evidence supporting an active method for therapists to implement MS strategies. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Doran, Churnalisa; Duits, Ashley; Tami, Adriana; Gerstenbluth, Izzy; Bailey, Ajay	2023	"It's very saddening, you keep on wondering when the symptoms will be over": A qualitative study exploring the long-term chikungunya disease impact on daily life and well-being, 6 years after disease onset	PLoS neglected tropical diseases	17	12	e0011793	BACKGROUND: Long-term chikungunya is a mosquito-borne disease, characterized by disabling rheumatic symptoms persisting for years, after infection with the chikungunya virus. Previous studies focused on assessing the well-being of affected individuals from a quantitative perspective using generic instruments, and have reported physical and psychological impairment. However, a common critique is that generic instrument's structured responses and pre-defined health domains selected by health professionals, may not capture the full extent of well-being impairment experienced by patients. This study aimed to explore in-depth to which extent long-term chikungunya disease impacts daily living and the physical, psychological, and social well-being from the experiences and perspective of affected individuals. METHODOLOGY/PRINCIPAL FINDINGS: Using open-ended questions, in-depth interviews were conducted with 20 purposively selected individuals with long-term chikungunya disease, in Curaçao. Interview audio-recordings were transcribed verbatim. The data were thematically analyzed. Living with persistent rheumatic symptoms affected the participant's daily living and well-being in several ways: experience of physical impact (restricted physical functioning and limitations in activities of daily life); experience of psychological impact

							<p>(altered emotional state, fear of walking and running, psychosocial aspects of footwear adaptations, and uncertainty about disease progression and future health); and experience of social impact (social isolation and impaired relational maintenance, social dependency, challenges of social support, at-work productivity loss, and giving up leisure activities after work).</p> <p>CONCLUSIONS/SIGNIFICANCE: This study, the first of its kind, indicated that the adverse impact of long-term chikungunya disease is currently underreported. The persistent rheumatic symptoms had a negative effect on functional ability, which in turn impacted broad aspects of daily life and well-being, beyond what is captured by generic instruments. In the view of the findings, physical exercise programs including manual therapy, aerobics, resistance and stretching exercises, and orthopaedic footwear interventions in a multidisciplinary patient-centred approach may improve physical function and subsequently overall well-being.</p>
Doran, Jennifer M.; Safran, Jeremy D.; Muran, J. Christopher	2016	The Alliance Negotiation Scale: A psychometric investigation	Psychological Assessment	28	8	885–897	<p>This study investigates the utility and psychometric properties of a new measure of psychotherapy process, the Alliance Negotiation Scale (ANS; Doran, Safran, Waizmann, Bolger, & Muran, 2012). The ANS was designed to operationalize the theoretical construct of negotiation (Safran & Muran, 2000), and to extend our current understanding of the working alliance concept (Bordin, 1979). The ANS was also intended to improve upon existing measures such as the Working Alliance Inventory (WAI; Horvath & Greenberg, 1986, 1989) and its short form (WAI-S; Tracey & Kokotovic, 1989) by expanding the emphasis on negative therapy process. The present study investigates the psychometric validity of the ANS test scores and interpretation—including</p>

							confirming its original factor structure and evaluating its internal consistency and construct validity. Construct validity was examined through the ANS' convergence and divergence with several existing scales that measure theoretically related constructs. The results bolster and extend previous findings about the psychometric integrity of the ANS, and begin to illuminate the relationship between negotiation and other important variables in psychotherapy research. Dorsey, Shannon; McLaughlin, Katie A.; Kerns, Suzanne E. U.; Harrison, Julie P.; Lambert, Hilary K.; Briggs, Ernestine C.; Revillion Cox, Julia; Amaya-Jackson, Lisa	2017	Evidence Base Update for Psychosocial Treatments for Children and Adolescents Exposed to Traumatic Events	Journal of clinical child and adolescent psychology : the official journal for the Society of Clinical Child and Adolescent Psychology, American Psychological Association, Division 53	46	3	303-330	Child and adolescent trauma exposure is prevalent, with trauma exposure-related symptoms, including posttraumatic stress, depressive, and anxiety symptoms often causing substantial impairment. This article updates the evidence base on psychosocial treatments for child and adolescent trauma exposure completed for this journal by Silverman et al. (2008). For this review, we focus on 37 studies conducted during the seven years since the last review. Treatments are grouped by overall treatment family (e.g., cognitive behavioral therapy), treatment modality (e.g., individual vs. group), and treatment participants (e.g., child only vs. child and parent). All studies were evaluated for methodological rigor according to Journal of Clinical Child & Adolescent Psychology evidence-based treatment evaluation criteria (Southam-Gerow & Prinstein, 2014), with cumulative designations for level of support for each treatment family. Individual CBT with parent involvement, individual CBT, and group CBT were deemed well-established; group CBT with parent involvement and eye movement desensitization and reprocessing (EMDR) were deemed probably efficacious; individual integrated therapy for complex trauma and group mind-body skills were

							deemed possibly efficacious; individual client-centered play therapy, individual mind-body skills, and individual psychoanalysis were deemed experimental; and group creative expressive + CBT was deemed questionable efficacy. Advances in the evidence base, with comparisons to the state of the science at the time of the Silverman et al. (2008) review, are discussed. Finally, we present dissemination and implementation challenges and areas for future research.
Douchis, Jennifer Zoler; Karam, Anna M.; Stein, Richard I.; Wilfley, Denise E.	2021	Subtyping patients with binge-eating disorder by dietary restraint and negative affect: Characteristics and treatment outcome	Journal of consulting and clinical psychology	89	12	1020–1025	Objective: This study examined patients with binge-eating disorder (BED) subtyped by dietary restraint (DR) and the negative affect (NA) dimension of depression, anxiety, hostility, and self-esteem, comparing clinical features and outcome of evidence-based psychological treatments. It was hypothesized that individuals with DR and high NA (DR-HNA) would have lower functioning and poorer immediate and long-term BED treatment outcomes compared to those with DR and low NA (DR-LNA). Method: Cluster analysis was conducted (n = 159) as a secondary analysis of data from a randomized group cognitive-behavioral therapy and interpersonal psychotherapy trial of women and men with BED. Results: At pretreatment, participants with DR-HNA were higher in eating disorder and general psychopathology, emotional eating, and poor social adjustment. At post-treatment, differences in binge days between cluster groups were small and statistically nonsignificant, and differences in rates of binge-eating abstinence were only marginally significant. However, by 1-year follow-up, patients with DR-HNA had a greater increase in binge days, less abstinence from binge eating, a higher risk for relapse, and were significantly less likely to be in BED remission than those with DR-LNA. Conclusions: DR-HNA served

							as a predictor of poorer maintenance of BED therapeutic improvement. Future directions to better sustain outcomes among patients with DR-HNA include developing a brief measure to assess for the full construct of NA prior to and throughout treatment, enhancing BED interventions by focusing more on NA, and augmenting treatment dose. Dowding, Kerry; Murphy, David; Everitt, Grant; Tickle, Anna	2023	Use of one-to-one psychotherapeutic interventions for people experiencing severe and multiple disadvantages: An evaluation of two regional pilot projects	Couns and Psychother Res (Counselling and Psychotherapy Research)	23	2	313-322	
Dowling, L. Emily; Jackson, Jeffrey B.; Landers, Ashley L.	2024	Gender role reversal: Civilian husbands of U.S. military servicewomen as tied-migrant workers	Fam Relat (Family Relations)	73	1	441-465	Abstract Objective This qualitative study examined the experiences of male spouses of female service members in the U.S. military (civilian husbands of servicewomen) in their positions as tied-migrant workers. Background Employment of civilian husbands of servicewomen is frequently affected when they geographically relocate due to their wives' military service. Because societal norms for husbands as primary breadwinners in marriages persist and the majority of military couples consist of male service members married to female civilian spouses, civilian husbands of servicewomen may experience a gender role reversal in their identities as a spouse and as a provider within their relationships and

						<p>military culture. Method Semistructured interviews were conducted with 22 civilian husbands who experienced at least one geographic relocation due to their wife's military service. Descriptive phenomenological analysis was used to discover the essence of participants' experiences. Results Themes around defining masculinity, minority experiences in the military, and nontraditional gender provider roles as tied-migrant workers emerged. Participants experienced a gender role reversal as tied-migrant workers and as military spouses, and they had some difficulties integrating into military communities. Participants expanded their masculine identities to include performing traditionally feminine tasks and valuing egalitarianism in their spousal relationships when they experienced barriers to breadwinning. Conclusion Findings indicated the importance of emotional support as civilian husbands navigate their masculine identities and relationships both with spouses and as gender minorities in their communities. Implications Clinical recommendations for psychotherapists are provided with an emphasis on using emotionally focused therapy with couples consisting of civilian husbands and servicewomen.</p>
Draxl, Katrin	2018	Essstörungen: Anorexie und Bulimie				<p>Rund 90 Prozent der an Essstörungen erkrankten Personen sind Mädchen und junge Frauen; Anorexie beginnt am häufigsten um das 14. Lebensjahr, der Krankheitsbeginn von Bulimie liegt um 2-3 Jahre später. Die Sterblichkeitsrate bei Anorexie wird in der Literatur mit 0-22 Prozent angegeben. Personen mit einer Essstörung sind meist schon seit einigen Jahren krank, bevor sie erstmals Hilfe in Anspruch nehmen. Grundsätzlich gilt: Je früher eine Essstörung erkannt und behandelt wird, desto besser sind die Chancen auf Gesundung. In diesem Artikel werden</p>

							nur die Anorexie und die Bulimie als prototypische Essstörungen besprochen. Essstörungen haben eine hohe Komorbidität mit Depression. Anorexie tritt häufig mit Zwangserkrankungen auf, Bulimie zusammen mit Angsterkrankungen. Die Borderline-Persönlichkeitsstörung wird immer wieder in Zusammenhang mit Bulimie genannt. Dreitzel, Hans Peter	2018	Die Rolle der Emotionen in der Gestalttherapie. Die Arbeit an der Ausdrucksfähigkeit unserer Gefühle	Psychotherapie im Dialog	19	1	93–98	Die Rolle der Emotionen in der Gestalttherapie wird erörtert. In der Gestalttherapie wird die Bedeutung der Emotionen vor allem in ihrer motivierenden und energetisierenden Funktion für das Handeln gesehen. Gefühle müssen allerdings ausgedrückt werden, um erlebt zu werden. Deshalb geht es in der Gestalttherapie um die Wiederbelebung der in neurotischen Prozessen verloren gegangenen emotionalen Ausdrucksfähigkeit und um eine Schulung des Bewusstseins für die Authentizität und die feinen Nuancen beim emotionalen Ausdruck. Eingegangen wird auch auf Störungen bei den aggressiven Gefühlen und die Rolle des Averbals in der gestalttherapeutischen Bearbeitung emotionaler Störungen.
Dreitzel, Hans Peter	2018	Die Sabotage von Introjekten. Einige Gedanken zur gestalttherapeutischen Bearbeitung von Introjekten in der sich verändernden Kultur	Gestalttherapie	32	2	26–48	Die gestalttherapeutische Bedeutung der Begriffe "Introjektion" und "Introjekt" wird erörtert, und es werden Hinweise zur ihrer therapeutischen Bearbeitung gegeben. Dabei wird die These vertreten, dass es der Knigsweg ihrer Bearbeitung ist, die fast immer und natürlicherweise auftretende "unbewusste Sabotage der Introjekte" therapeutisch zu unterstützen. Abschließend wird anhand einer Analyse der "politischen Korrektheit" unterschieden zwischen neurotischen Introjekten und gesunden, zivilisatorisch notwendigen Verinnerlichungen.

In ihrem Beitrag berichtet sie von ihren Erfahrungen und von den Rckmeldungen der Jugendlichen.
Drinane, Joanna M.; Owen, Jesse; Tao, Karen W.	2018	Cultural concealment and therapy outcomes	Journal of Counseling Psychology	65	2	239-246	Therapy is predicated on the need for clients to share intimate details about their lives, including their cultural values, attitudes, and beliefs. Previous studies have found that clients conceal certain aspects of their lives including, but not limited to their symptoms and their feelings about the therapy process. To date, there has not been an investigation focused on whether clients conceal aspects of their cultural identities, whether some therapists are more likely to have clients conceal aspects of their cultural identities, and if cultural concealment is associated with therapy outcomes. The present study attempted to do so utilizing the caseloads of 37 therapists who treated a total of 233 clients in a university

						<p>counseling center setting. Client data were collected at the end of treatment utilizing the Patient's Estimate of Improvement (PEI; Hatcher & Barends, 1996), a measure that assesses client change on domains including general functioning, symptom related distress, intimate and social relationships, work or school, feelings about oneself, behavior, control of life, and tolerance for and ability to share painful feelings. Cultural concealment was assessed via 5 items regarding the amount and circumstances under which clients withheld cultural identity based information in therapy. Results indicated that within therapists' caseloads, client's ratings of cultural concealment were negatively associated with therapy outcomes. Additionally, therapists whose clients rated more cultural concealment on average had clients with worse therapy outcomes. Lastly, there was a significant contextual effect indicating that within and between therapist cultural concealment were statistically different from one another. (PsycINFO Database Record (c) 2018 APA, all rights reserved)</p>
<p>Drinane, Joanna M.; Roberts, Tangela; Winderman, Kate; Freeman, Vanessa Frierson; Wang, Yu-Wei</p>	<p>2022</p>	<p>The myth of the safe space: Sexual orientation disparities in therapist effectiveness</p>	<p>Journal of Counseling Psychology</p>	<p>69</p>	<p>3</p>	<p>Psychotherapy has been shown to be effective on a broad level (e.g., Wampold & Imel, 2015); however, a growing body of literature has revealed that some therapists have outcome inequities within their caseloads. These inequities have been observed on the basis of social identities including race (see Imel et al., 2011, for example) and gender measured on the binary (Owen et al., 2009). However, despite the great need for further research on sexual minority populations in psychotherapy, this phenomenon has yet to be explored on the basis of sexual orientation (i.e., if a disparity exists within-therapist caseloads between queer-identified and heterosexual clients). The present study was comprised</p>

							of a sample of 1,725 clients treated by 50 therapists at a university counseling center (17.7% of the sample endorsed a sexual minority status). Multilevel modeling was used to analyze data from the Behavioral Health Measure-20 (BHM-20; Kopta & Lowry, 2002). The results indicated that clients' sexual orientation status was not significantly associated with any of the BHM-20 subscales or with the Global Mental Health Scale (GMH). Of interest was that therapists varied in the extent to which their clients' symptoms and GMH improved and how that improvement varied by client sexual orientation status. Thus, attention must be paid not only to which therapists are more and less effective overall, but also to the specifics of which clients (and the social identities those clients hold) are improving while under their care. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Dring, Else	2018	Das Gutachten zur Humanistischen Psychotherapie. Folgen für die Anerkennung der Gesprächspsychotherapie	Psychotherapie Aktuell	10	4	12-13	Im ablehnenden Gutachten des Wissenschaftlichen Beirates Psychotherapie (WBP) zur Humanistischen Psychotherapie wird festgestellt, dass die Gesprächspsychotherapie (GT) den Kriterien des aktuellen Methodenpapiers des WBP nicht mehr genügt und dass deshalb für die GT die wissenschaftliche Anerkennung nicht mehr gültig ist. Es wird der Frage nachgegangen, welche Konsequenzen sich aus dieser Beurteilung der GT für die Anerkennung der Ausbildungsinstitute durch die Landesbehörden, für die Weiterbildungsordnungen der Landeskammern und für approbierte oder weitergebildete Gesprächspsychotherapeuten ergeben.

Duberstein, Paul R.; Ward, Erin A.; Chaudron,		Effectiveness of interpersonal psychotherapy-trauma for	Journal of consulting and clinical psychology	86	10	<p>Background: Women with depression and childhood sexual abuse histories constitute more than 20% of the female patient population in publicly funded community mental health centers (CMHCs). Interventions are</p>

Linda H.; He, Hue; Toth, Sheree L.; Wang, Wenjuan; van Orden, Kimberly A.; Gamble, Stephanie A.; Talbot, Nancy L.		depressed women with childhood abuse histories					<p>needed that address depression and posttraumatic stress disorder (PTSD) symptoms and social health. Method: We compared Interpersonal Psychotherapy-Trauma (IPT-T), an IPT adaptation for this population and setting, to Clinic Psychotherapy (CP). CP clinicians were free to implement the psychotherapy of choice. Women (n = 162; 54% White, 10.5% Hispanic; 52.2% Medicaid-insured) with a major depressive episode (MDE) and history of sexual abuse before 18 were randomly assigned to IPT-T or CP. Participants were offered 16 free sessions of IPT-T or CP. Outcomes were MDE remission, improved depression (Beck Depression Inventory, Hamilton Depression Rating Scale) and PTSD symptoms (Modified PTSD Symptom Scale), and improved social health (e.g., UCLA Loneliness Scale). Weighted generalized estimating equations were used to examine outcomes at 8 (primary) and 20 (secondary) months postrandomization. Results: IPT-T led to greater improvements in PTSD symptoms and many social health indicators, including loneliness and social support, at both 8- and 20-month follow-up. Effect sizes ranged from .18 to .39 at the primary endpoint (8 months). IPT-T and CP yielded comparable improvements in depression symptoms and MDE remission. Conclusion: Evidence-based psychotherapies like IPT-T are needed in CMHCs, where some of the most vulnerable patients receive treatment. With comparable findings for depression, IPT's superior improvements in social health and PTSD symptoms are cause for optimism. IPT-T should be evaluated in dissemination trials. Duffy, Kate E. M.; Simmonds-Buckley,		Early response as a prognostic indicator in	Journal of Counseling Psychology	69	6		Currently, no reports exist on the phenomenon of early response in humanistic–experiential therapies. This study investigated the prognostic value of early response on

Melanie; Saxon, David; Delgadillo, Jaime; Barkham, Michael		person-centered experiential therapy for depression				<p>posttreatment outcomes in person-centered experiential therapy (PCET) for depression within the English Improving Access to Psychological Therapies program. The design of the study was a retrospective observational cohort study. Routine clinical data were drawn from N = 3,321 patients with depression symptoms. The primary outcome was reliable and clinically significant improvement (RCSI) on the Patient Health Questionnaire-9 (PHQ-9) self-report depression measure at the end of treatment. Early response was operationalized as reliable improvement, defined as a PHQ-9 change score ≥ 6 from baseline to Session 4. Early response was examined as a predictor of RCSI using logistic regression controlling for baseline depression severity. In sensitivity analyses, therapist effects were controlled using multilevel modeling. A total of 38.7% of patients met the criterion for early response. Patients who experienced an early response to treatment were six times more likely to recover at the end of treatment compared to patients who did not have an early response. The early response effect was still evident after accounting for individual variability between therapists. However, a quarter of patients displayed a pattern of eventual response, reaching recovery at end of treatment despite not experiencing an initial improvement early in therapy. Early response to PCET is a reliable predictor of treatment outcome. Different response patterns evidenced in this study indicate that identifying subgroups of patients associated with early and eventual response could support clinical decision-making. Dulsster, Dries; Vanheule, Stijn;	2021	Lacanian discourse	Psychoanalytic Psychology	38	4	The present study aims at mapping and interpreting factors that stand out as being relevant to personal

<p>Cauwe, Joachim; Ingouf, Junior; Hennissen, Vicky; Miller, Alexander Reid</p>		<p>theory and the process of change in Lacanian-oriented talking therapies</p>				<p>change through Lacanian-oriented psychoanalytic talking therapy, starting from accounts offered by Lacanian psychoanalysts of therapies they conducted. Using interview data on how these psychoanalysts perceived the therapeutic journey of their patients, we applied a thematic analysis to gain insight into what these psychoanalysts believed effectuated change that occurred for their patients. Second, we interpret the data within the context of Lacan’s discourse theory, one of the models proposed by Lacan to grasp the process of psychoanalysis. We discerned three principal themes. Participants indicated that their patients entered therapy with an insisting question related to their own functioning, which was further provoked by the analysts. Second, by embodying the element of the unsaid, the analysts focused on the speech of their patients, creating a space to critically listen to what their patients were saying, so their patients were able to reflect on the motives that could have been influencing their words and actions. The psychoanalysts focused on the subjective logic of patients’ functioning; the specific ways patients dealt with challenges in the subject–other relationship. Lacanian structural diagnoses served as a means of reorienting treatment toward a person-centered case construction. Third, the articulation of subjectively important symbolic material (master signifiers) was a key, allowing patients to “let go” of the repetitive impact these master signifiers had on their life. Remarkably, while positioned in the analytic discourse, analysts nonetheless used other discourses to incite further elaboration, intervening with surprising flashes. Duncan, Barry L.; Reese, Robert J.; Lengerich,	2021	Measurement-based care in integrated health care: A	Families, Systems, & Health	39	2	<p>Introduction: Many suggest that the next step for integrated care is widespread implementation of measurement-based care (MBC). Although the measures most associated with MBC are standardized, no</p>

Alexander J.; DeSantis, Brian; Comeau, Cassie V.; Johnson- Esparza, Yajaira		randomized clinical trial					<p>randomized clinical trial has demonstrated their use to improve psychotherapeutic outcomes with embedded behavioral health providers in integrated care. Two evidence-based MBC systems have been studied in a variety of behavioral health environments, but neither system has been investigated in integrated health care. Addressing this gap in the literature, the present study evaluated the use of MBC, specifically the Partners for Change Outcome Management System, in three integrated care sites. Method: Using a randomized design within routine care, treatment as usual (TAU; n = 133) was compared using the Outcome Rating Scale (ORS) and Patient Health Questionnaire–9 (PHQ–9) with a feedback condition (n = 147) in which behavioral health providers had access to patient-generated outcome (ORS only) and alliance information at each session. Results: Patients in the feedback condition demonstrated significantly more improvement than those in the TAU condition posttreatment on the ORS. Patients in the feedback condition also achieved significantly more clinically significant change as measured by both the ORS and PHQ–9. Feedback condition patients also attended significantly more sessions and dropped out significantly less than TAU patients. Discussion: Although our findings need to be replicated, this study offers evidence that the improved outcomes and reduced dropouts associated with MBC in traditional behavioral health centers also occur in integrated care settings. Dunn, Nicole A.; Luchner, Andrew F.	2022	The emotional impact of self-criticism on self-reflection and rumination	Psychology and psychotherapy	95	4	1126–1139	<p>OBJECTIVES</p> <p>The goals of this study were to determine whether self-reflection is a beneficial exercise for highly self-critical individuals and to examine the effects of self-focused thought including reflection and rumination on mood. This was investigated by measuring the levels of self-criticism, as well as mood before and after exposure to a reflective prompt or a ruminative prompt.</p> <p>DESIGN</p> <p>Experimental design with random assignment to reflection, rumination or control groups.</p> <p>METHODS</p> <p>243 participants from a sample recruited on prolific provided demographic information and completed measures of current mood and self-criticism. All participants were then asked to remember a time they made a mistake that had a significant impact on them and describe the mistake briefly. Participants were then randomly assigned to a self-focus condition (reflection, rumination or control). After being assigned and completing the prompt, their mood was measured again.</p> <p>RESULTS</p> <p>Hierarchical multiple regressions were used to measure the potential combined effects of self-criticism and self-focused thought on change in emotion. The results showed that participants with high levels of maladaptive self-criticism (hated self-subscale) experienced a significant decrease in negative emotions, indicating improved mood.</p> <p>CONCLUSIONS</p>

							This suggests that reflection may be a beneficial exercise for highly self-critical individuals. Participants in the rumination group experienced no significant change in emotion, indicating how rumination can perpetuate negative affect and is therefore an important issue to be addressed in psychotherapy.
Dunne, John D.; Thompson, Evan; Schooler, Jonathan	2019	Mindful meta-awareness: sustained and non-propositional	Current opinion in psychology	28		307–311	Meta-awareness appears to be essential to nearly all forms of mindfulness practice, and it plays a key role in processes that are central to therapeutic effects of mindfulness training, including decentering - shifting one's experiential perspective onto an experience itself - and dereification or metacognitive insight - experiencing thoughts as mental events, and not as the things that they seem to represent. Important advances in the conceptualization of meta-awareness in mindfulness have recently been made, yet more clarity is required in order to characterize the type of meta-awareness implicated in the ongoing monitoring of attention and affect, even while attention itself is focused on an explicit object of awareness such as the breath. To enhance research on this form of meta-awareness cultivated in at least some styles of mindfulness, a construct of sustained, non-propositional meta-awareness is proposed.
Duquette, Patrice	2020	More Than Words Can Say: A Multi-Disciplinary Consideration of the Psychotherapeutic Evaluation	Frontiers in psychiatry	11		433	Alexithymia is a disorder that stands at the border of mind and body, with psychological/affective and physiological/experiential disturbances. The purpose of this article is to propose a new clinical access point for the evaluation and treatment of the deficits in emotional awareness demonstrated in alexithymia. This will be based on insights from recent neuroscientific research, which is adding to the psychodynamic understanding of alexithymia, regarding clinical presentation and etiology.

		and Treatment of Alexithymia					<p>Following a brief review of definitions, forms of measurement, and potential etiologic elements of alexithymia, current neuroscientific theory and research into "predictive processing" approaches to brain function will be outlined, including how "interoception" and "interoceptive inference" underpins emotion and emotional awareness. From this synergistic perspective, I will outline how interoceptive inference provides a key to the link between: problems in early life relational experiences and the patient's long held, but suboptimal models of their inner and outer world. This is reflected in the deficits in affective experiencing and emotional awareness described in alexithymia. Three clinical cases will be presented to illustrate this nuanced consideration of alexithymic etiology and treatment. The implications of the historical, psychological, and somatic aspects of experience will be considered, regarding the patients' diminished ability to: experience and represent emotional experience as distinct feeling states; signify the relevant meaning of affective experience; and incorporate such with cognitions to adaptively guide behavior. These will be addressed using psychometric, psychological, neuro-cognitive, and neurocomputational approaches. Elements from current theory, research, and treatment of alexithymia, will be highlighted that are salient to the clinician, in order to support their understanding of patients against the backdrop of current psychodynamic and neuroscientific research, which will thereby increase treatment options and benefits. The focus, and conclusion, of this article is the role that attention to interoception can play (within the safety of the therapeutic relationship and within any therapeutic</p>
--	--	------------------------------	--	--	--	--	--

							process) in allowing updating of the patient's strongly held but dysfunctional beliefs.
Dwyer, Jennifer B.; Stringaris, Argyris; Brent, David A.; Bloch, Michael H.	2020	Annual Research Review: Defining and treating pediatric treatment-resistant depression	Journal of child psychology and psychiatry, and allied disciplines	61	3	312–332	<p>BACKGROUND</p> <p>Adolescent major depressive disorder (MDD) is a significant health problem, associated with substantial morbidity, cost, and mortality. Depression is a significant risk factor for suicide, which is now the second leading cause of death in young people. Up to twenty per cent of adolescents will experience MDD before adulthood, and while a substantial proportion will improve with standard-of-care treatments (psychotherapy and medication), roughly one third will not.</p> <p>METHODS</p> <p>Here, we have reviewed the literature in order to discuss the concept of treatment-resistant depression (TRD) in adolescence, examine risk factors, diagnostic difficulties, and challenges in evaluating symptom improvement, and providing guidance on how to define adequate medication and psychotherapy treatment trials.</p> <p>RESULTS</p> <p>We propose a staging model for adolescent TRD and review the treatment literature. The evidence base for first- and second-line treatments primarily derives from four large pediatric clinical trials (TADS, TORDIA, ADAPT, and IMPACT). After two medications and a trial of evidence-based psychotherapy have failed to alleviate depressive symptoms, the evidence becomes quite thin for subsequent treatments. Here, we review the evidence for the effectiveness of medication switches, medication augmentation, psychotherapy augmentation, and interventional treatments (i.e., transcranial magnetic stimulation, electroconvulsive therapy, and ketamine) for adolescent TRD. Comparisons are drawn to the adult TRD</p>

							literature, and areas for future pediatric depression research are highlighted. CONCLUSIONS As evidence is limited for treatments in this population, a careful consideration of the known risks and side effects of escalated treatments (e.g., mood stabilizers and atypical antipsychotics) is warranted and weighed against potential, but often untested, benefits.
Dymoke, Katy	2019	Touching the untouchables	Psychother Politics Int (Psychotherapy and Politics International)	17	3		
Dyurich, Adriana; Prasad, Veena; Mueller, Deborah; Hutcherson, Lisa; Kempenich, Jason W.; Dent, Daniel; Botros-Brey, Sylvia	2023	Lived Experiences of Mistreatment in a General Surgery Residency	Journal of surgical education	80	3	385-392	OBJECTIVE: Explore the lived experiences of General Surgery residents to identify how they perceive, define mistreatment, and which factors can contribute to or mitigate mistreatment within the Clinical Learning Environment. DESIGN: This is a phenomenological study conducted during 2019-2020 using Giorgi's psychological descriptive phenomenology methodology. Researcher bias, trustworthiness, and triangulation were addressed using bracketing, check-ins with program leadership, comparisons to resident survey, and team consensus based on Consensual Qualitative Research. SETTING: General Surgery Residency program at Long School of Medicine, UT Health San Antonio, Texas. PARTICIPANTS: All residents in the general surgery program were invited to participate (n= 66, 43% female and 63% non-Hispanic). Specific demographic and identifying data for each participant was not collected. Approximately 50 (76% of program) residents from General Surgery participated. RESULTS: We were able to identify four themes that helped to delineate the lived experience of residents

						including program cultural factors, resident internal processing, and perceived effects of mistreatment by the residents. The resulting psychological structure and conceptual framework help clarify the interrelations between the themes and the Clinical Learning Environment. The scenarios discussed were adapted and depersonalized to use as prompts for the Forum Theater intervention. This project set out to explore resident's lived experiences and allow the data to reveal the main outcomes. The data was coded and analyzed following strict guidelines from descriptive psychological phenomenology and Consensual Qualitative Research with the aim of informing a later experiential intervention based on Forum Theater. CONCLUSIONS: The lived experience of general surgery residents helped identify cultural factors and behaviors that contribute to and/or mitigate mistreatment providing information to plan interventions at the resident and faculty level. Mitigating or stopping mistreatment can improve the Clinical Learning Environment and hence, the quality of training.
Eadeh, Hana-May; Adamowicz, Jenna L.; Markon, Kristian; Thomas, Emily B. K.	2023	Using network analysis to examine connections between Acceptance and Commitment Therapy (ACT) processes, internalizing symptoms, and well-being in a	Journal of affective disorders	320	701-709	BACKGROUND: Acceptance and Commitment Therapy (ACT) has been shown to be effective in treating internalizing symptoms. Understanding which ACT processes are most closely linked to certain symptoms may help develop targeted treatments. Network analysis an approach to gain insight into the interconnection between processes and the downstream benefits of targeting a particular process. However, limited work to date has explored networks involving ACT processes specifically. METHODS: Undergraduate students (N = 447; 76.5 % female; 89.5 % White/Non-Hispanic) completed online questionnaires. The ACT processes assessed included experiential avoidance (AAQ-II),

		sample of undergraduates					<p>openness, awareness, and engagement (CompACT), and tacting ability (TOF), and internalizing symptoms/well-being (IDAS-II). Zero-order and partial correlation networks were examined as well as resulting communities. RESULTS: In the association network, dysphoria and experiential avoidance, and suicidality (in the concentration network only) were central nodes. In community analyses, experiential avoidance had the strongest influence in the association network, whereas well-being had the strongest influence in the concentration network. Auto-detected communities were also evaluated. LIMITATIONS: The present study was cross-sectional and included a largely White, female, undergraduate sample. This limits generalizability to more diverse, clinical, or general community populations. Potential concerns about data are also noted including low reliability on the TOF and two skewed domains on the IDAS-II which may impact stability of centrality metrics. CONCLUSIONS: Well-being, dysphoria, and suicidality may be important process-based treatment targets. Further work is needed with diverse samples and using longitudinal designs to examine within person change of the associations between ACT processes and internalizing symptoms.</p>
Eady, Kaylee; Moreau, Katherine A.	2018	Observing the influence of the physical environment on family involvement in a rehabilitation setting	Families, Systems, & Health	36	4	493–506	<p>Introduction: Health professionals and institutions need to understand how to facilitate family involvement within settings designed prior to the adoption of patient- and family-centered philosophies. This study sought to explore how the physical environment of an inpatient rehabilitation setting influenced family involvement in health care delivery. Method: We conducted this study on the inpatient acquired brain injury ward of a Canadian adult rehabilitation center. This study used a basic</p>

							<p>interpretive qualitative approach. We conducted observations of how the physical environment influenced the conversations, interactions, and activities, which were central to family involvement, in this setting. We used a systematic qualitative analysis method. This study received research ethics board approval prior to commencing. Results: We conducted 26 2-hr observation sessions. Five sessions occurred in the morning, 17 in early and late afternoon, and 4 in the evening. Eighteen sessions occurred on a weekday and 8 on a weekend day. The following 6 categories emerged from the field data: (a) accessing health professionals, (b) awareness of family presence, (c) facilitating family presence, (d) facilitating patient-family activities, (e) providing information for families, and (f) facilitating family involvement in therapy. Discussion: This study provided information to inform future discussions and strategies for facilitating family involvement within the existing physical environments of health care institutions. Initial steps should consider ways to help families feel welcomed, such as including additional seating in spaces, posting signage inviting families into spaces, having resources tailored to families readily available, and creating a visible sign-in/sign-out board for families. (PsycINFO Database Record (c) 2018 APA, all rights reserved)</p>
Early, Macy L.; Strodel, Rachel J.; Lake, Isabel V.; Ruddy, Jake A.; Saba, James A.; Singh, Sajya M.; Lanzkron, Sophie; Mack,	2022	Acceptable, hopeful, and useful: development and mixed-method evaluation of an educational tool	Journal of assisted reproduction and genetics	39	1	183-193	<p>PURPOSE: People with sickle cell disease (SCD) or trait have many reproductive options, some of which decrease the chance of passing SCD to children, including in vitro fertilization with preimplantation genetic testing (IVF + PGT). Few are aware of these options, and educational materials are needed. This study aimed to develop an accessible, non-directive patient education material about reproductive options for those with SCD or trait via</p>

Jennifer W.; Meier, Emily R.; Christianson, Mindy S.; Pecker, Lydia H.		about reproductive options for people with sickle cell disease or trait					a process that incorporated stakeholders from the SCD community. METHODS: Multidisciplinary stakeholders guided development and revision of a novel pamphlet. Researchers applied health literacy scales to measure pamphlet understandability. We interviewed nine patients with SCD and six multidisciplinary clinicians to evaluate the pamphlet. Interviews were recorded, transcribed, and coded by a five-member team who developed a codebook and proposed themes that were revised by all research team members. Feedback was incorporated into a revised pamphlet. RESULTS: A two-page pamphlet describing reproductive options for people with SCD including IVF + PGT was acceptable to key stakeholders, including people with SCD. Material about this complex topic met health literacy standards, including being written at a 5th grade level. Patients reported feeling hopeful after reviewing the pamphlet, and participants considered the pamphlet useful, clear, and appropriate for distribution in clinics and online. CONCLUSIONS: Though awareness of reproductive options for those with SCD or trait is low, patients and providers find a novel pamphlet about this topic acceptable and useful. Educational materials about complex topics including IVF + PGT can be written at a level understandable to the average American.
Echiverri- Cohen, Aileen; Zoellner, Lori A.; Gallop, Robert; Feeny, Norah; Jaeger, Jeffrey; Bedard-Gilligan, Michele	2016	Changes in temporal attention inhibition following prolonged exposure and sertraline in the	Journal of consulting and clinical psychology	84	5		Objective: Attentional inhibitory deficits expressed as difficulty ignoring irrelevant stimuli in the pursuit of goal-directed behavior may serve as a fundamental mechanism of posttraumatic stress disorder (PTSD). Evidence of inhibitory processes as central to extinction suggests that exposure-based treatments may act more directly on the inhibitory deficits implicated in PTSD, whereas, in facilitating serotonergic neurotransmission,

		treatment of PTSD					selective serotonin reuptake inhibitors (SSRIs) may be less direct and bring about general neurochemical changes in the fear circuitry. If these inhibitory deficits underlie PTSD, then inhibition should improve with successful treatment, with those treated with prolonged exposure (PE) potentially resulting in greater changes in inhibition than those treated with sertraline. Method: Changes in temporal attentional inhibition, using an attentional blink (AB) paradigm, were examined at pre- and posttreatment in 49 individuals (74.5% female, 66.7% Caucasian, age M = 37.69, SD = 12.8 years) with chronic PTSD. Participants completed 10 weeks of either PE or sertraline. Results: Individuals who made greater improvements with PE showed faster improvements in temporal inhibition on the critical inhibitory lag of AB than those who made greater improvements with sertraline (d = 0.94). These changes could not be accounted for by basic attention. Conclusions: Greater improvement in fundamental attentional inhibitory processes with better treatment response to PE, compared with sertraline, suggests potential specificity in how PTSD treatments normalize inhibitory processes, such that exposure-based treatments like PE may target inhibitory processes and improve basic inhibitory functioning. Ecker, Saan; Lykins, Amy	2023	“Voted yes—What else can I do?”: Coping with stigma-related stress during the Australian	Psychology of Sexual Orientation and Gender Diversity	10	2	324–336	There is limited empirical evidence on how LGBTIQ (Lesbian, Gay, Bisexual, Transgender, Intersex and Queer/Questioning) people cope with stigma-related stress associated with marriage amendment processes. The current study explored coping during the 2017 Australian Marriage Law Postal Survey during which stigma-related stress was significantly associated with increased psychological distress of LGBTIQ people. Data

		marriage equality debate					collected during the voting and debate period from 5,453 LGBTIQ respondents were analyzed, investigating relationships between coping strategies and psychological distress. In keeping with this study's aims to provide scholarship on the poorly understood relationship between coping with stigma-related stress and mental health of LGBTIQ people, qualitative data were used to complement quantitative analysis. Emotion-focused, avoidant coping strategies of reactive distancing and disengagement was associated with increased psychological distress, as expected. However, contrary to expectations based on coping and stress theories, problem-focused, adaptive coping strategies, including LGBTIQ community engagement and activism, problem solving, positive reappraisal, and seeking social support were not associated with reduced psychological distress. Results reveal the limitations of problem-focused coping in the context of extreme stigma-related stress, with adaptive coping efforts commonly unsuccessful due to highly pervasive stressors. Findings also highlight that typical problem-focused coping strategies may not be sufficient for dealing with identity threats such as those experienced during this period. Findings support the importance of structural equality in reducing psychological distress of minorities and indicate the need for improved community and therapeutic support and addressing stigma-related stress as a social, rather than individual phenomenon. Eckert, Jochen	2016	Hat die Gesprchspsych otherapie/Perso nzentrierte Psychotherapie eine Zukunft? Eine Stellungnahme zu dem Beitrag von Behr, M., Finke J., Gahleitner, S. B. (2016). "Personzentriert sein - Sieben Herausforderun gen der Zukunft". PERSON 40 (1): 14-30	Person	20	2	97-100	Es wird Stellung zum Beitrag von M. Behr, J. Finke & S. B. Gahleitner (in PERSON 2016, 40 (1)) genommen, welcher die Potenziale, den Personzentrierten Ansatz (PZA) konzeptionell weiterzuentwickeln, thematisierte. Dabei wird kritisiert, dass in dem Artikel nicht erwht wird, dass es seit 2008 in Deutschland keine staatlich anerkannte Ausbildung zum Psychologischen Psychotherapeuten mit Schwerpunkt Gesprchstherapie mehr gibt. Damit wird der Personzentrierten Psychotherapie als Psychotherapieverfahren nach derzeitigem Stand der Dinge in Deutschland keine Zukunft attestiert. Vor diesem Hintergrund werden vier Grnde fr den zurckgehenden Einfluss der Gesprchspsychotherapie/Personzentrierten Psychotherapie in Deutschland errtert: (1) Das Stagnieren empirischen Forschung, (2) Ausbleiben eines konsequenten Vorgehens gegen falsche Darstellungen des PZA, (3) Mangelhafte Sorgfalt und fehlende Wiedergabe der Klientenzentrierten Persnlichkeits- und Therapietheorie durch Vertreter des PZA und (4) Mangelhafte bzw. fehlende Bezugnahme bei Verffentlichungen von PZA-Autoren auf bereits vorliegende Publikationen.
Eckert, Jochen	2019	Wissenschaftlic her Beirat Psychotherapie: Quo vadis?. Eine Frage, die erneut gestellt werden muss	Psychotherapeu t	64	5	420-425	Fnf Jahre nach Einberufung eines "Wissenschaftlichen Beirats Psychotherapie" (WBP) gem 11 Psychotherapeutengesetz wurde 2001 eine kritische Bilanz der Arbeit dieses Gremiums vorgelegt. Das im Januar 2018 verffentliche Gutachten des WBP zur wissenschaftlichen Anerkennung der humanistischen Psychotherapie gibt erneut Anlass zu einer kritischen Stellungnahme. Am Beispiel der Bewertung der Gesprchspsychotherapie wird dargelegt, dass bestimmte

							gutachterliche Empfehlungen des WBP in hohem Maße von berufspolitischen Interessen bestimmt werden.
Eckert, Jochen	2018	Borderline-Persnlichkeitsstrungen					Das konkrete therapeutische Vorgehen bei der Psychotherapie von Borderline-Persnlichkeitsstrungen hngt zum einen davon ab, welchen therapietheoretischen Hintergrund der Therapeut hat, und zum anderen davon, welche Annahmen zur Entstehung der Strung zugrunde gelegt werden. Die Standardbehandlungsprozeduren, wie sie ursprnglich fr die Therapie von Personen mit sogenannten neurotischen Strungen entwickelt wurden, sind im Hinblick auf die Besonderheiten der BPS jeweils modifiziert worden. Eine psychotherapeutische Behandlung dieser Patienten ist schwierig und langwierig, die Abbruchraten und Rckfallquoten sind hoch, und die Patienten sind stark suizidgefhrdet. Daher sollte die auf die besondere Verletzlichkeit von Borderline-Patienten abgestimmte Beziehungsaufnahme bereits in der diagnostischen Phase beginnen. (c) Springer-Verlag GmbH Deutschland
Eckert, Jochen	2016	Bindungstheorie und Humanistische Psychotherapie					Die Bedeutung der Bindungstheorie wird aus der Sicht der Humanistischen Psychotherapie ertert. Fokussiert werden folgende Aspekte: (1) Die Bedeutung einer emotionalen zwischenmenschlichen Beziehung fr die menschliche Entwicklung. (2) Grundannahmen der Gesprchpsychotherapie zur Persnlichkeitsentwicklung. (3) Die Persnlichkeitstheorie von Rogers und die Bindungstheorie von Bowlby im Vergleich. (4) Zur Qualitt der Beziehung zwischen Kind und Pflegeperson (die Qualitt einer bindungsfrdernden Beziehung aus Sicht der Bindungstheorie und die Qualitt einer die psychische Stabilitt frdernden Beziehung aus Sicht der Gesprchpsychotherapie). (5) Mentalisierung und empathische Erfassung des "Inneren Bezugsrahmens". (6)

							Ein empirischer Vergleich von "Mentalisierung" und "Selbstexploration". Abschließend wird der Frage nachgegangen, welchen praktischen Gewinn humanistische Therapieansätze aus den Erkenntnissen der Bindungsforschung ziehen können.
Eckert, Jochen; Biermann- Ratjen, Eva- Maria	2020	Gesprächspsych otherapie mit PatientInnen mit einer Borderline- Persönlichkeitsst rung	Gesprächspsych otherapie und Personzentrierte Beratung	51	4	18–23	Das zentrale Therapeutikum der Gesprächspsychotherapie ist ihr Beziehungsangebot: Der/die TherapeutIn bemüht sich, die PatientIn in ihrem Erleben bedingungsfrei positiv zu beachten und empathisch genau zu verstehen. Dieser Beitrag beschreibt und erlutert, wie sich die Symptomatik des/r Borderline-PatientIn, die vor allem Ausdruck einer Beziehungsstrung ist, auf die Möglichkeiten des/r PatientIn auswirkt, dieses Beziehungsangebot wahr- und anzunehmen. Es wird dargestellt, wie der/die GesprächspsychotherapeutIn damit umgehen kann und dass ein/e TherapeutIn, die eine/n Borderline-PatientIn in Therapie nimmt, sich auf eine krisenanflüge Langzeitbehandlung einstellen sollte. Der Beitrag schließt mit Empfehlungen zum therapeutischen Rahmen bzw. Versorgungsaspekten.
Eckert, Jochen; Biermann- Ratjen, Eva- Maria	2019	Die Traumatheorie in der Gesprächspsych otherapie nach Carl R. Rogers					
Eckert, Jochen; Schwab, Reinhold	2017	Diagnostik in der Gesprächspsych otherapie					Der Stellenwert der Diagnostik in der Gesprächspsychotherapie wird im Überblick dargestellt. Dabei wird auf diagnostische Verfahren und Vorgehensweisen im Rahmen der Eingangsdiagnostik (Indikation und Prognose), der Prozessdiagnostik (Therapieverlauf) und der Erfolgsdiagnostik bzw. Nachtestung (Therapieergebnis) jeweils gesondert

							eingegangen. Es wird betont, dass Diagnostik in der Gesprächspsychotherapie eine lange Tradition hat, dass sie durch C. Rogers' Credo begründet wurde, dass es erforderlich sei, den psychotherapeutischen Prozess und seine Effekte empirisch zu erforschen, und dass Diagnostik in der Gesprächspsychotherapie niemals Selbstzweck war und ist, sondern der - vor allem prozessbegleitenden - Evaluation und Qualitätssicherung diene und dient.
Edmondstone, Chris; Pascual-Leone, Antonio; Soucie, Kendall; Kramer, Ueli	2023	Therapist effects on outcome: Meaningful differences exist early in training	Training and Education in Professional Psychology		19 31- 39 26(Electronic), 19 31- 39 18(Print)	149-157	Therapist effects are well-established in the literature, but their presence in the earliest stages of a therapist's career (i.e., training) is under-studied. The present study involved the investigation of between-therapist effects—differences between therapists' average effectiveness (i.e., outcome ratings) across all patients in their caseloads—within the context of an outpatient psychotherapy clinic where graduate-level trainee therapists are trained. The clinical outcomes of N = 202 clients who were treated by N = 35 therapists practicing two or more of cognitive behavioural therapy, emotion-focused therapy, brief psychodynamic psychotherapy, and integrative psychotherapy were examined for differential effectiveness of therapists. Results indicated that, after already accounting for effects related to therapeutic orientation and clinical experience, therapists-in-training differed in significant ways as measured by the average magnitude and rate of change of clients in their caseloads, as well as clients' end-of-therapy clinical classification. The implications of broad performance discrepancies among trainee therapists are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)

<p>Edwards, Caitlin; Allan, Robert; Marzo, Nick; Wynfield, Ted; Hicks, Ryan</p>	<p>2023</p>	<p>The use of emotionally focused therapy with polyamorous relationships</p>	<p>Family process</p>	<p>62</p>	<p>4</p>	<p>1362–1376</p>	<p>Approximately 5% of people in the United States engage in some form of consensual non-monogamy (CNM; Archives of Sexual Behavior, 2018, 47, 1439). Therapists are becoming increasingly aware of the need to treat members of CNM relationships, including polyamorous relationships. To date, no research has been conducted and little has been written about applying existing couple therapy models normed on heterosexual, cisgender, monogamous relationships to CNM or polyamorous relationships. Emotionally focused therapy (EFT) is an empirically supported treatment for relationship distress that offers promise for working with polyamorous relationships due to the model's systemic and attachment theoretical foundations. We propose EFT is an ideal model for working with polyamorous relationships because of the focus on externalizing, interpersonal and intrapersonal emotional and experiential coherence, and the attachment bond. Building and sustaining multiple attachment relationships allows for the fulfilment of a diverse range of relational needs and wants as well as provides a secure base for individual and relational exploration. In this article, we first provide general information about polyamory and discuss the research on attachment theory and polyamory. We then provide a step-by-step conceptualization of how EFT therapists can expand the model to include extra-dyadic attachment relationships. In addition, we include specific ways in which the model would need to be adapted when working with polyamorous clients. We conclude with recommendations for EFT therapists working with polyamorous relationships.</p>

Edwards, Emily; Shivaji, Sindhuja; Wupperman, Peggilee	2018	The Emotion Mapping Activity: Preliminary evaluation of a mindfulness-informed exercise to improve emotion labeling in alexithymic persons	Scandinavian J Psychology (Scandinavian Journal of Psychology)	59	3	319–327	Alexithymia is a psychoemotional trait associated with many treatment-resistant psychological and social difficulties. Research suggests that these difficulties stem primarily from an inability to appropriately apply linguistic labels to emotional experiences and content. The present research introduces and preliminarily evaluates a novel mindfulness-informed exercise to improve emotion-labeling ability in alexithymic persons. Based in culturally universal patterns of somatic experience, the Emotion Mapping Activity (EMA) directs alexithymic persons to reflect on their internal, somatic experiences as a source of information for interpreting and labeling emotional experiences. In the present study, 67 alexithymic persons completed a series of emotion-labeling tasks either with or without assistance of the EMA. Results suggest that completion of the EMA may improve ability to label emotions that would be otherwise misinterpreted - without interfering with labeling that is already intact. Though further research is necessary, the present study suggests that the EMA may hold the potential to be incorporated into psychotherapy protocols as an exercise for improving emotion-labeling ability in alexithymic clients.
Eftekhari, Afsoon; Crowley, Jill J.; Mackintosh, Margaret-Anne; Rosen, Craig S.	2020	Predicting treatment dropout among veterans receiving prolonged exposure therapy	Psychological Trauma: Theory, Research, Practice, and Policy	12	4	405–412	Objective: To examine whether dropout from prolonged exposure (PE) therapy can be predicted from demographic and outcomes data that would typically be available to clinicians. Methods: Dropout was examined in 2,606 patients treated by clinicians in the U.S. Veterans Health Administration PE Training Program. PE typically consists of 8–15 sessions, with 8 sessions being considered a minimum therapeutic dose for most patients. Logistic regression was used to assess the impact of demographics, depression, trauma history, and

						PE target trauma on risk for dropout. Growth mixture modeling was used to study how posttraumatic stress disorder symptom patterns during the first 5 treatment encounters predicted dropout. Results: In total, 782 patients (30.0%) completed fewer than 8 sessions of PE. Younger veterans were more likely to drop out of PE; odds ratio (OR) per year of age = 0.97, p p < .05). Dropout was unrelated to symptom course or symptom worsening between sessions. Nevertheless, clinicians attributed dropout to distress or avoidance in 45% of the patients who dropped out, citing other factors in 37% of dropout cases. Conclusions: Treatment dropout was predicted by age but not by initial symptom severity or symptom course early in treatment. Symptom exacerbation was rare and did not increase risk of dropout. Nonetheless, clinicians often attributed dropout to patients not tolerating PE. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Eggenberger, Lukas; Komlenac, Nikola; Ehlert, Ulrike; Grub, Jessica; Walther, Andreas		Association between psychotherapy use, sexual orientation, and traditional masculinity among psychologically distressed men	Psychology of Men & Masculinities	23	4	Heterosexual-identified men, as compared to non-heterosexual-identified men, are less likely to seek out psychotherapy when experiencing psychological distress. Stronger endorsement of traditional masculinity ideologies (TMI) has been reported to be associated with reduced psychotherapy use among men. However, the relationship between psychotherapy use, TMI, and sexual orientation needs to be explored. A total of 728 psychologically distressed men (59.9% heterosexual-identified, 40.1% non-heterosexual-identified) from German-speaking parts of Europe completed an online questionnaire asking about current psychotherapy use, endorsement of TMI, experienced gender role conflict (GRC), prototypical depression symptoms, and externalizing depression symptoms. In total 34.5% (n =

						<p>251) of the men were currently using psychotherapy, of which 47.4% (n = 119) identified as heterosexual and 52.6% (n = 132) as non-heterosexual. Heterosexual-identified men used psychotherapy less than non-heterosexual-identified men, while exhibiting lower prototypical depression symptoms but comparable externalizing depression symptoms. Additionally, heterosexual-identified men exhibited higher endorsement of TMI across all domains and experienced more masculine GRC, especially in the domains Success Concerns and Restricted Affection. Endorsement of TMI was associated with increased externalizing depression symptoms only among heterosexual-identified men. Logistic regression analyses showed stronger endorsement of TMI, increased externalizing depression symptoms, and identifying as heterosexual to be associated with reduced psychotherapy use. Men identifying as heterosexual with strong endorsement of TMI, and high externalizing depression symptoms have a reduced likelihood to use psychotherapy. Thus, challenging TMI and advocating for alternative masculinities that include health promoting behavior can especially help heterosexual-identified men with strong TMI. Egli, Samy; Frie, Elisabeth; Graf, Patricia; Hhn, David; Kopf-Beck, Johannes; Rein, Martin Ludwig; Ruderer,	2019	Schematherapie bei Depressionen. Ein Behandlungskonzept für das (teil)stationäre Setting				<p>In einem Manual werden praxisorientierte Fertigkeiten zur schematherapeutischen Behandlung von depressiven Strungen im (teil-)stationären Kontext vermittelt. Neben einer Einführung zum Strungsbild der Depression werden Grundlagen der Schematherapie und die Arbeit mit dem Modus-Modell vorgestellt. Bei Depressionen zeigen sich zwei Modus-Konstellationen besonders häufig: Zum einen können erdulden und vermeidende Anteile im</p>

<p>Amelie; Szesny-Mahlau, Nicole; Zimmermann, Petra; Keck, Martin Ekkehard</p>						<p>Vordergrund stehen, zum anderen aber auch kontrollierende Anteile. Diese beiden Ausprägungen werden ausführlich erlutert und das therapeutische Vorgehen daraus abgeleitet. Die Behandlung verluft ber sieben Wochen, in denen je 14 Gruppen- und Einzelsitzungen angeboten werden. Die Patientinnen und Patienten knnen flexibel in die teiloffenen Gruppen einsteigen, die idealerweise von zwei Therapeuten angeleitet werden. Im Vordergrund der Behandlung stehen die beiden emotions- und erfahrungsfokussierten Techniken Stuhldialog und Imagination. Oft ist es dabei zielfhrend, von der vorgegebenen inhaltlichen Struktur einer Therapiesitzung abzuweichen, um unmittelbar auf emotionale Reaktionen und Modus-Aktivierungen bei den Patienten einzugehen. Der flexible Umgang mit diesen Abweichungen von der Struktur zugunsten der Emotions- und Bedrfnisorientierung wird ausfhrlich erklrt. Fr die Arbeit mit den verschiedenen Modi knnen "Modicons" eingesetzt werden (zum Ausdruck auf der beiliegenden CD-ROM). Diese Bilder erleichtern die Kommunikation und knnen zeigen, welcher Modus aktiv ist. Weiterhin werden hilfreiche Strategien vermittelt, um den Herausforderungen der schematherapeutischen Arbeit auf der Beziehungsebene zu begegnen. - Inhalt: (1) Einfhrung (Schematherapie - Modi und Modicons, bergeordnete Ziele, Zielgruppe, Einzel- und Gruppensitzungen; allgemeine psychotherapeutische Prinzipien; Aufbau und Struktur des Manuals). (2) Diagnostik und Behandlung der Depression (Epidemiologie; tiologie; Erscheinungsbild und Diagnostik; Psychotherapie; Psychopharmakologie; weitere Methoden). Ehr, Dorothea; Link, Pierre-Carl	2016	Pldoyer fr eine kritische Betrachtung des Spannungsverhltnisses von Vulnerabilitt und Resilienz am Beispiel der Selbst- und Emotionsregulation nach Berking	Zeitschrift fr Gestaltpdagogik	27	2	22–35	Das Spannungsverhltnis zwischen Resilienz und Vulnerabilitt im Rahmen der Emotionsregulation und Selbstregulation wird beschrieben. Nach einer Darstellung des Resilienzkonzepts nach Mathias Berking wird seine praktische Relevanz fr Psychotherapie und Erziehung sowie fr die Prvention oder Abmilderung der Folgen von Entwicklungsrisiken erlutert. Anschließend wird die Polaritt von Resilienz und Vulnerabilitt ausgefhr. Vor diesem Hintergrund wird fr einen Vulnerabilittsdiskurs in der pdagogischen resilienzorientierten Gestaltarbeit pldiert.
Eisele, Marion; Boczor, Sigrid; Rakebrandt, Anja; Blozik, Eva; Träder, Jens-Martin; Störk, Stefan;	2017	General practitioners' awareness of depressive symptomatology is not associated with	BMC family practice	18	1	100	BACKGROUND: Depression is a common comorbidity in patients with chronic heart failure (HF) and linked to a wider range of symptoms which, in turn, are linked to a decreased health-related quality of life (HRQOL). Treatment of depression might improve HRQOL but detecting depression is difficult due to the symptom overlap between HF and depression. Therefore, clinical

<p>Herrmann-Lingen, Christoph; Scherer, Martin</p>	<p>quality of life in heart failure patients - cross-sectional results of the observational RECODE-HF Study</p>				<p>guidelines recommend to routinely screen for depression in HF patients. No studies have so far investigated the treatment after getting aware of a depressive symptomatology and its correlation with HRQOL in primary care HF patients. Therefore, we examined the factors linked to depression treatment and those linked to HRQOL in HF patients. We hypothesized that GPs' awareness of depressive symptomatology was associated with depression treatment and HRQOL in HF patients. METHODS: For this observational study, HF patients were recruited in primary care practices and filled out a questionnaire including PHQ-9 and HADS. A total of 574 patients screened positive for depressive symptomatology. Their GPs were interviewed by phone regarding the patients' comorbidities and potential depression treatment. Descriptive and regression analysis were performed. RESULTS: GPs reported various types of depression treatments (including dialogue/counselling by the GP him/herself in 31.8% of the patients). The reported rates differed considerably between GP-reported initiated treatment and patient-reported utilised treatment regarding psychotherapy (16.4% vs. 9.5%) and pharmacotherapy (61.2% vs. 30.3%). The GPs' awareness of depressive symptomatology was significantly associated with the likelihood of receiving pharmacotherapy (OR 2.8; $p < 0.001$) but not psychotherapy. The patient's HRQOL was not significantly associated with the GPs' awareness of depression. CONCLUSION: GPs should be aware of the gap between GP-initiated and patient-utilised depression treatments in patients with chronic HF, which might lead to an undersupply of depression treatment. It remains to be investigated why GPs' awareness of depressive</p>
--	---	--	--	--	--

							symptomatology is not linked to patients' HRQOL. We hypothesize that GPs are aware of cases with reduced HRQOL (which improves under depression treatment) and unaware of cases whose depression do not significantly impair HRQOL, resulting in comparable levels of HRQOL in both groups. This hypothesis needs to be further investigated.
Eismann, Gunnar	2021	Emotionsregulation. 75 Therapiekarten					In einem Kartenset werden 75 Therapiekarten zum Thema Emotionsregulation präsentiert. Emotionsregulatorische Kompetenzen können gezielt gefördert werden. Dies zu erreichen und die Arbeit mit Emotionen für bedürfnisorientierte Veränderungsprozesse nutzbar zu machen, sind die Ziele dieses Kartensets. Gegliedert in sieben Module, können die Karten themenbezogen eingesetzt werden. Sie führen vom Verständnis und der Akzeptanz für Emotionen hin zu Strategien aktiver Emotionsregulation. Eine punktuelle Auswahl einzelner Karten sowie deren flexible modulbergreifende Vernetzung sind möglich. So kann die Therapie individuell und bedürfnisgerecht angepasst werden. Der emotionsfokussierte Charakter der Therapiekarten intensiviert die psychotherapeutische Arbeit. Innovative Techniken und Übungen, emotional ansprechende Bilder und Anleitungen zur Selbstreflexion bieten einen erlebnisorientierten Zugang zur Thematik. Die Karten eignen sich für den Einsatz in Psychotherapie, Supervision, Selbsterfahrung und psychologischer Beratung, im Einzel- oder Gruppensetting. - Inhalt: https://d-nb.info/1231247657/04
Eisterer, Angelika; Dungal-Nemetz, Sabine	2021	Halt geben - Die offene Stabilisierungsgg	Zeitschrift für Psychodrama und Soziometrie	20	Su ppl 1	77-92	In diesem Beitrag der Zeitschrift für Psychodrama und Soziometrie wird eine offene Stabilisierungsgruppe mit zahlreichen Beispielen und Übungen beschrieben. Die

		ruppe bei FAIRTHERAPY					Gruppe ist ein offenes, gruppentherapeutisches Angebot für (komplex) traumatisierte Menschen. Aufgrund dieser Zielgruppe und des offenen Settings bedarf es eines speziellen Aufbaus, einer speziellen Haltung in der Begegnung und einer sorgfältigen Auswahl der gesetzten Interventionen. Diese werden sowohl mit psychodramatischer als auch existenzanalytischer Theorie erklärt. Besondere Bedeutung haben die Rahmenbedingungen und Grundhaltungen, das Eingehen auf die Struktur der teilnehmenden Personen und die Phasen der Gruppentherapie sowie das Herstellen einer Gruppenkohäsion trotz offenen Settings. (c) Springer Fachmedien Wiesbaden GmbH
Ekeblad, Annika; Falkenström, Fredrik; Andersson, Gerhard; Vestberg, Robert; Holmqvist, Rolf	2016	Randomized Trial of Interpersonal Psychotherapy and Cognitive Behavioral Therapy for Major Depressive Disorder in a Community-Based Psychiatric Outpatient Clinic	Depression and anxiety	33	12	1090–1098	<p>BACKGROUND Interpersonal psychotherapy (IPT) and cognitive behavioral therapy (CBT) are both evidence-based treatments for major depressive disorder (MDD). Several head-to-head comparisons have been made, mostly in the United States. In this trial, we compared the two treatments in a small-town outpatient psychiatric clinic in Sweden. The patients had failed previous primary care treatment and had extensive Axis-II comorbidity. Outcome measures were reduction of depressive symptoms and attrition rate.</p> <p>METHODS Ninety-six psychiatric patients with MDD (DSM-IV) were randomized to 14 sessions of CBT (n = 48) or IPT (n = 48). A noninferiority design was used with the hypothesis that IPT would be noninferior to CBT. A three-point difference on the Beck Depression Inventory-II (BDI-II) was used as noninferiority margin.</p> <p>RESULTS IPT passed the noninferiority test. In the ITT group, 53.5%</p>

						<p>(23/43) of the IPT patients and 51.0% (24/47) of the CBT patients were reliably improved, and 20.9% (9/43) and 19.1% (9/47), respectively, were recovered (last BDI score <10). The dropout rate was significantly higher in CBT (40%; 19/47) compared to IPT (19%; 8/43). Statistically controlling for antidepressant medication use did not change the results.</p> <p>CONCLUSIONS</p> <p>IPT was noninferior to CBT in a sample of depressed psychiatric patients in a community-based outpatient clinic. CBT had significantly more dropouts than IPT, indicating that CBT may be experienced as too demanding. Since about half the patients did not recover, there is a need for further treatment development for these patients. The study should be considered an effectiveness trial, with strong external validity but some limitations in internal validity.</p>
Ekeblad, Annika; Falkenström, Fredrik; Holmqvist, Rolf		Reflective functioning as predictor of working alliance and outcome in the treatment of depression	Journal of consulting and clinical psychology	84	1	<p>Aims: Although considerable attention has been paid to the concept of mentalization in psychotherapy, there is little research on mentalization as predictor of psychotherapy process and outcome. Using data from a randomized controlled trial of cognitive-behavioral therapy and interpersonal psychotherapy for depression, we studied mentalization in 85 outpatients with major depressive disorder (MDD) according to the Diagnostic and Statistical Manual of Mental Disorders. It was hypothesized that patients showing lower capacity for mentalization would experience poorer quality of alliance and worse outcome. Method: Depressive symptoms were measured each session using the Beck Depression Inventory—II. Mentalization was measured as reflective functioning (RF) on a slightly shortened version of the Adult Attachment Interview. A measure of depression-</p>

							<p>specific reflective functioning (DSRF), measuring mentalization about depressive symptoms, was also used. The Working Alliance Inventory—Short Form Revised was completed after each session by both therapist and patient. Longitudinal multilevel modeling was used to analyze data. Results: The patients had on average very low RF ($M = 2.62$, $SD = 1.22$). Lower pretreatment RF/DSRF predicted significantly lower therapist-rated working alliance during treatment. RF did not affect patient-rated alliance, but lower DSRF predicted lower patient-rated alliance across treatment. Patients with higher RF/DSRF had better outcomes on self-rated depression. Conclusions: The findings showed lower than normal capacity for mentalization in patients with MDD. Lower RF/DSRF predicted worse treatment outcome. More research is needed to understand how RF affects psychotherapy response and how RF is affected after recovery from depression. (PsycINFO Database Record (c) 2018 APA, all rights reserved)</p>
Ekstrand, Maria L.; Rawat, Shruta; Patankar, Pallav; Heylen, Elsa; Banu, Asha; Rosser, B. R. Simon; Wilkerson, J. Michael	2017	Sexual identity and behavior in an online sample of Indian men who have sex with men	AIDS care	29	7	905–913	<p>Indian men who have sex with men are disproportionately impacted by HIV. While prevention efforts to date have focused on men who visit drop-in centers or physical cruising sites, little is known about men who are meeting sexual partners on virtual platforms. This paper explores issues related to sexual identity and sexual behaviors in an online sample of men who identified as gay ($n = 279$) or bisexual ($n = 123$). There were significant differences in outedness between the two groups, with 48% of bisexually identified men reporting that they were out to "no one" and 82% stating that they present themselves as heterosexual to family and friends. Corresponding rates for gay-identified men were 15% and 41%, respectively (both $p < .001$). Twenty-nine percent of bisexually</p>

							<p>identified men reported being married, compared to only 3% of the gay-identified men ($p < .001$). Bisexually identified men were also more likely to report having exclusively insertive anal sex (49% vs 30% $p < .001$), while gay-identified men were more likely to report exclusively receptive anal sex (41% vs 13% $p < .0001$). Rates of unprotected anal sex (UAS) in the two groups were similar; however, married men were significantly more likely to report unprotected vaginal sex (76% vs 35%, $p < .012$). Positive attitudes toward UAS and lower self-efficacy were associated with sexual risk in both groups; however, substance use was associated with sexual risk only among bisexually identified men. These findings show that a large proportion of Indian bisexually identified men lead closeted lives, especially in their interactions with friends and family, with the vast majority presenting as heterosexual. The lower condom use with wives may be due to societal pressures to have children. The results suggest that bisexually identified men may benefit from targeted programs and non-directive, non-judgmental individual or couples counseling which emphasizes condom use with both male and female partners.</p>
El-Alti, Leila; Sandman, Lars; Munthe, Christian	2022	Caregiver perspectives on patient capacities and institutional pathways to person centered forensic psychiatric care	PloS one	17	9	e0275205	<p>The ethical discourse surrounding patients' agential capacities, vis-à-vis their active participation in shared decision-making (SDM) in forensic psychiatric (FP) contexts, is an unexplored area of inquiry. The aim of this paper is to explore caregivers' perceptions of patient agential capacities and institutional pathways and barriers to person centered care (PCC) in the context of FP. Following an exploratory qualitative design, we conducted eight semi-structured interviews with hands-on caregivers at an in-patient FP facility in Sweden. A deductive framework method of analysis was employed,</p>

							and four themes emerged: "Fundamental Variability in Patient Capacity", "Patient Participation: Narration or Compliance?", "Antagonism Rooted in Power Struggles", and "System Structure Thwarts Patient Release". While the results generally paint a bleak picture for the possibility of a person-centered FP care, we describe a constrained version of PCC with high-level SDM dynamics which promotes a certain degree of patient empowerment while allowing care strategies, within set restrictions, to promote patient adherence and treatment progress.
Elfrink, Teuntje R.; Zuidema, Sytse U.; Kunz, Miriam; Westerhof, Gerben J.	2018	Life story books for people with dementia: a systematic review	International psychogeriatrics	30	12	1797–1811	ABSTRACT Objectives: There is an increasing evidence that reminiscence therapy is effective in improving cognitive functions and reducing depressive symptoms in people with dementia. Life story books (LSBs) are frequently used as a reminiscence tool to support recollecting autobiographical memories. As little is known about how LSBs are used and what type of studies have been employed to evaluate LSB interventions, we conducted a systematic review. METHODS: The electronic databases Scopus, PubMed, and PsychINFO as well as reference lists of existing studies were searched to select eligible articles. Out of the 55 studies found, 14 met the inclusion criterion of an original empirical study on LSBs in people with dementia. RESULTS: The majority of the LSBs were tangible books, although some digital applications were also found. The LSBs were created mostly in individual sessions in nursing homes with a median of six sessions. Some studies only focused on the person with dementia, while others also examined (in)formal caregivers. Most studies used qualitative interviews, case studies, and/or (pilot) randomized controlled trial (RCTs) with small sample sizes. Qualitative findings showed the value of

						<p>LSBs in triggering memories and in improving the relation with the person with dementia. Quantitative effects were found on, e.g. autobiographical memory and depression of persons with dementia, quality of relationship with informal caregivers, burden of informal caregivers, and on attitudes and knowledge of formal caregivers.</p> <p>CONCLUSIONS: This systematic review confirms that the use of LSBs to support reminiscence and person-centered care is promising, but larger RCTs or implementation studies are needed to establish the effects of LSBs on people with dementia.</p>	
<p>Elices, Matilde; Carmona, Cristina; Narváez, Vanessa; Seto, Victoria; Martín-Blanco, Ana; Pascual, Juan C.; Soriano, José; Soler, Joaquim</p>	2017	<p>Direct experience while eating: Laboratory outcomes among individuals with eating disorders versus healthy controls</p>	Eating behaviors	27		23–26	<p>OBJECTIVE: To compare individuals with eating disorders (EDs) to healthy controls (HCs) to assess for differences in direct engagement in the eating process. METHOD: Participants (n=58) were asked to eat an orange slice. To assess the degree of direct engagement with the eating process, participants were asked to write down 10 thoughts about the experience of eating the orange slice. Next, the participants were instructed to classify the main focus of each thought as either experiential ("direct experience") or analytical ("thinking about"). A direct experience index (DEI) was computed by dividing the number of times that participants classified an experience as a "direct experience" (the numerator) by the total number of all observations (i.e., direct experience+thinking about). Participants also completed the Five Facet Mindfulness Questionnaire (FFMQ) and the Experiences Questionnaire (EQ) to assess mindfulness facets and decentering, respectively. RESULTS: Compared to controls, participants in the EDs group presented significantly lower levels of direct experience during the eating task (EDs group: mean=43.54, SD=29.64; HCs group: mean=66.17, SD=22.23, p=0.03).</p>

							Participants in the EDs group also scored significantly lower on other mindfulness-related variables. DISCUSSION: These findings suggest that engagement with the direct experience of eating is lower in individuals with EDs. Future research should investigate the role of mindfulness-based interventions to address direct experience while eating in individuals with EDs.
Elliott, Robert; Bohart, Arthur C.; Watson, Jeanne C.; Murphy, David	2018	Therapist empathy and client outcome: An updated meta-analysis	Psychotherapy		19 39- 15 36(Ele ctr oni c), 00 33- 32 04(Pri nt)	399–410	Put simply, empathy refers to understanding what another person is experiencing or trying to express. Therapist empathy has a long history as a hypothesized key change process in psychotherapy. We begin by discussing definitional issues and presenting an integrative definition. We then review measures of therapist empathy, including the conceptual problem of separating empathy from other relationship variables. We follow this with clinical examples illustrating different forms of therapist empathy and empathic response modes. The core of our review is a meta-analysis of research on the relation between therapist empathy and client outcome. Results indicated that empathy is a moderately strong predictor of therapy outcome: mean weighted $r = .28$ ($p < .001$; 95% confidence interval [.23, .33]; equivalent of $d = .58$) for 82 independent samples and 6,138 clients. In general, the empathy–outcome relation held for different theoretical orientations and client presenting problems; however, there was considerable heterogeneity in the effects. Client, observer, and therapist perception measures predicted client outcome better than empathic accuracy measures. We then consider the limitations of the current data. We conclude with diversity considerations and practice recommendations, including endorsing the different forms that empathy may take in

							therapy. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Elliott, Robert; Macdonald, James	2021	Relational dialogue in emotion-focused therapy	Journal of clinical psychology	77	2	414-428	In emotion-focused therapy (EFT) relational processes between the therapist and client are not normally an explicit focus unless the therapist and client encounter difficulties that interfere with therapeutic work. When this does happen, however, relational dialogue (including meta-communication) becomes necessary. We present the principles and stages of the EFT task Relational Dialogue for Alliance Difficulties. After describing this little-known task, we illustrate its application in the successful treatment of a severely socially anxious female client with complex trauma and emotional fragility. Using transcripts and detailed descriptions we highlight the alliance difficulty marker subtype, relational dialogue principles and the stages of EFT alliance difficulty work. 2020 Wiley Periodicals LLC.
Ellis, Kate; Hosny, Nadine; Miller-Graff, Laura	2022	User experiences of a culturally adapted web-based intervention for posttraumatic stress disorder in Egypt: A qualitative study	Psychotherapy	59	1	13-25	The following study describes the usability and the acceptability of an online intervention for the treatment of posttraumatic stress disorder (PTSD), PTSD Coach Online that was culturally adapted and translated into local Egyptian dialect. The adapted intervention was piloted in a randomized control trial with 87 Egyptians meeting clinical criteria for a diagnosis of PTSD. Of the 41 participants who participated in the treatment condition, 15 participants (10 females, 5 males) were randomly selected to take part in a semistructured interview to explore their user experience. Favorable feedback centered on the program's ease of access, user-friendly tools, and cultural appropriateness. Participants also described benefits including increased awareness of PTSD, symptom reduction, and increased willingness to seek psychological support online or in person. In

							contrast, participants highlighted some drawbacks of the online program, particularly the need for further support or some kind of “human” interaction as well as feelings that the information was not sufficiently personalized and that activities could have been more interesting. The findings suggest that while the PTSD Coach Online-Arabic is unlikely to be an effective stand-alone support, approximately half of the sample indicated that the availability of online tools is important for accessibility of mental health care, particularly for those concerned with stigma. As such, it may be an important supplemental offering for other forms of ongoing care and support. Future research may consider integrated approaches to care that were highlighted as being of particular interest to participants. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Ellis, Mark A.; Sterba, Katherine R.; Day, Terry A.; Marsh, Courtney H.; Maurer, Stacy; Hill, Elizabeth G.; Graboyes, Evan M.	2019	Body Image Disturbance in Surgically Treated Head and Neck Cancer Patients: A Patient-Centered Approach	Otolaryngology-head and neck surgery : official journal of American Academy of Otolaryngology-Head and Neck Surgery	161	2	278-287	OBJECTIVE: To promote patient-centered oncology care through an in-depth analysis of the patient experience of body image disturbance (BID) following surgery for head and neck cancer (HNC). STUDY DESIGN: Qualitative methods approach using semistructured key informant interviews. SETTING: Academic medical center. SUBJECTS AND METHODS: Participants with surgically treated HNC underwent semistructured key informant interviews and completed a sociodemographic survey. Recorded interviews were transcribed, coded, and analyzed using template analysis to inform creation of a conceptual model. RESULTS: Twenty-two participants with surgically treated HNC were included, of whom 16 had advanced stage disease and 15 underwent free tissue transfer. Five key themes emerged characterizing the participants' lived experiences with BID following HNC treatment: personal dissatisfaction with

						appearance, other-oriented appearance concerns, appearance concealment, distress with functional impairments, and social avoidance. The participant's perceived BID severity was modified by preoperative patient expectations, social support, and positive rational acceptance. These 5 key themes and 3 experiential modifiers form the basis of a novel, patient-centered conceptual model for understanding BID in HNC survivors. CONCLUSION: A patient-centered approach to HNC care reveals that dissatisfaction with appearance, other-oriented appearance concerns, appearance concealment, distress with functional impairments, and social avoidance are key conceptual domains characterizing HNC-related BID. Recognition of these psychosocial dimensions of BID in HNC patients can inform development of HNC-specific BID patient-reported outcome measures to facilitate quantitative assessment of BID as well as the development of novel preventative and therapeutic strategies for those at risk for, or suffering from, BID.
Ellis, Robyn A.; Meyer, Emilie; Cole, Travis A.; Orcutt, Holly K.	2023	The dynamic relationship of negative emotional content in the context of trauma-focused writing interventions on improvements in cognitive reappraisal: A pilot study	Psychological Trauma: Theory, Research, Practice, and Policy		No Paginat ion Specified -No Paginat ion Specified	Objective: Writing about traumatic experiences is beneficial for the reduction of posttraumatic stress symptoms, yet little research has examined the linguistic content of trauma-focused writing interventions. The current pilot study had two aims (a) characterize changes in linguistic features in two trauma-focused writing interventions; and (b) examine how changes in linguistic content may be associated with proposed mechanisms of change in trauma treatment (i.e., emotion regulation, cognitive reappraisal, and experiential avoidance). Method: Data were a secondary analysis of a proof-of-concept trial of written exposure therapy (WET) compared to trauma-focused expressive writing. Participants (N =

						<p>33, 76% female) completed five virtual sessions and measures of emotion regulation, posttraumatic cognitions, and experiential avoidance. Reliable change was calculated for each mechanism pre/postintervention. Linguistic inquiry and word count (Boyd et al., 2022) was used to analyze linguistic content (i.e., negative emotion words, past tense, cognitive processing, and death-related content). Results: Group differences emerged in slopes of narrative content across time for negative emotion words ($b = 0.3, p = .008$), past tense ($b = -1.45, p = 0.39, p = .002$). Contrary to expectations, only the slope of change in negative emotion words was associated with reliable changes in posttraumatic cognitions ($b = -0.59, p = .023$). Conclusions: Findings contribute evidence to support the use of negative emotion words early in treatment as a potentially influential target for improving posttraumatic cognitions in WET. Emanu, Jessica C.; Avildsen, Isabelle; Nelson, Christian J.	2024	Psychotherapeutic Treatments for Male and Female Sexual Dysfunction Disorders			253–270	<p>Abstract Sexual dysfunction is a common class of disorders and refers to difficulty experienced by an individual or a couple during any stage of a normal sexual experience, including in terms of physical pleasure, desire, preference, arousal, and orgasm. Additionally, sexual dysfunctions are typically caused or exacerbated by psychological distress, and, with this in mind, psychological interventions are important treatment options to explore. This chapter reviews the available psychotherapies for male and female sexual disorders in terms of both research support for the overall therapy and support for the putative mechanism of change that underlies the treatment. There have been several established therapies designed specifically for sexual</p>

							dysfunctions, including cognitive-behavioral therapy (CBT), sex therapy, behavioral therapy, educational interventions, and other psychotherapies, which include mindfulness meditation therapies, hypnotherapy, and rational emotive therapy. Sex therapy is a psychotherapeutic treatment that focuses on immediate factors within a couple's sexual interactions.
Emanuele, Marco; Polletta, Giovanni; Marini, Maddalena; Fadiga, Luciano	2022	Developmental Coordination Disorder: State of the Art and Future Directions from a Neurophysiological Perspective	Children (Basel, Switzerland)	9	7		Developmental coordination disorder (DCD) is a common neurodevelopmental condition characterized by disabling motor impairments being visible from the first years of life. Over recent decades, research in this field has gained important results, showing alterations in several processes involved in the regulation of motor behavior (e.g., planning and monitoring of actions, motor learning, action imitation). However, these studies mostly pursued a behavioral approach, leaving relevant questions open concerning the neural correlates of this condition. In this narrative review, we first survey the literature on motor control and sensorimotor impairments in DCD. Then, we illustrate the contributions to the field that may be achieved using transcranial magnetic stimulation (TMS) of the motor cortex. While still rarely employed in DCD research, this approach offers several opportunities, ranging from the clarification of low-level cortical electrophysiology to the assessment of the motor commands transmitted throughout the corticospinal system. We propose that TMS may help to investigate the neural correlates of motor impairments reported in behavioral studies, thus guiding DCD research toward a brain-oriented acknowledgment of this condition. This effort would help translational research to provide novel diagnostic and therapeutic tools.

Embregts, Petri J C M; Ahaus, Kees; Minkman, Mirella; Nies, Henk; Meurs, Pauline	2021	A sector-wide response to national policy on client-centred care and support: a document analysis of the development of a range of instruments to assess clients' experiences in the care and support for people with (intellectual) disabilities	BMC health services research	21	1	1307	<p>BACKGROUND: Client-centred care serves as the foundation for healthcare policy. Indeed, various instruments for assessing clients' experiences of care and support are increasingly used to provide insights into the quality, and client-centred nature, of the care and support provided, which, in turn, aids the development of subsequent improvements. The unique characteristics of care and support for people with intellectual disabilities (ID), such as the need for both lifelong and life-wide care and support across all aspects of clients' lives, led to an initiative within Dutch ID care to jointly develop a range of instruments to assess the experiences of clients receiving ID care and support. Individual clients' experiences and suggestions for improvement, which are embedded in clients' care plan cycles, constitute the foundation of this Range of Instruments. This paper provides a unique, bottom-up, exhaustive account of the process of developing the Range of instruments used to assess the experiences of clients in the field of Dutch ID care.</p> <p>METHODS: Relevant documents at three levels (i.e. 1) national documents, such as policy papers and governmental reports, 2) documents and reports from the Dutch Association of Healthcare Providers for People with Disabilities (VGN) along with minutes from the meetings of the expert Committee who assessed the instruments, and 3) correspondence between the Committee and developers as well as the forms used in the assessment process for each instrument) were qualitatively analysed by two researchers who had no affiliation with the development of the Range of instruments used to assess clients' experiences in ID care and support. All of the documents were inductively coded using a thematic analytical approach. Informants who were either</p>
---	------	---	------------------------------	----	---	------	---

							<p>currently or previously involved in the development of these instruments were asked to provide clarification over the documents themselves and to explain the context in which they were produced. RESULTS: The development of the range of instruments can be classified into four phases, namely: 1) supporting the bottom-up development of initiatives to assess clients' experiences, 2) focusing on learning and further development, 3) stimulating exchange between the developers and users of the instruments and the Committee responsible for assessing them, and 4) further development in response to the changing times and new landscape.</p> <p>CONCLUSIONS: The range of instruments were found to be appropriate for a variety of clients in ID care and support, specifically in terms of assessing their individual experiences and gaining insight into their suggestions for improvement, and effective in terms of collaboratively improving the quality of ID care and support. In so doing, these instruments potentially provide an avenue through which clients' experiences can be embedded in the process of ID care and support. Other specific features in the development of these instruments, namely their incremental adoption, ongoing evaluation and strong practice orientation, were also found to be suitable for other care contexts' attempts to respond to the top-down policy objectives of client-centeredness and translating outcomes into direct care practice.</p>
Endermann, Michael	2019	Psychotherapie bei erwachsenen Menschen mit Lernschwierigkeiten in stationärer	Verhaltenstherapie und psychosoziale Praxis	51	4	805–820	<p>In der vorliegenden naturalistischen Praxisstudie werden die Wirkungen von Psychotherapie bei 32 Personen mit leichten Intelligenzminderungen beziehungsweise Borderline-Intelligenz, die sich in stationärer Betreuung der von Bodenschwingschen Stiftungen Bethel befanden, in einem Pr-Post-Design untersucht. Von den Klientinnen</p>

		Betreuung. Ein Praxisbericht als Beitrag zur Qualitätssicherung					und Klienten waren mehr als 80 % zusätzlich epilepsiekrank. Zu Beginn und am Ende der Therapie kamen das "Brief Symptom Inventory" (BSI), das "Inventory of Interpersonal Problems" (IIP) sowie die "Self-esteem Scale" zum Einsatz. Signifikante Verbesserungen fanden sich beim Gesamtwert des BSI und des IIP, die Effektstärken lagen im mittleren und geringen Bereich. Verbesserte Werte im IIP zeigten sich im Zusammenhang mit dem Einsatz von Gesprächspsychotherapie als Therapie-Basismethodik. Für die Subskala "Wertlosigkeit" der "Self-esteem Scale" ergab sich ein mittlerer Effekt in die gewünschte Richtung. Diese Verbesserung stand im Zusammenhang mit längerer Therapiedauer und mehr Therapiestunden. Der Verfasser schlägt für die Evaluation von Psychotherapien bei Menschen mit Lernschwierigkeiten eine ergänzende oder alternative Erfassung von Zielparametern, beispielsweise (gesellschaftliche) Teilhabe, sowie eine systematische Erfassung von Merkmalen des Therapiesettings und damit verbundener interprofessioneller Zusammenarbeit vor.
Engelhardt, Anne-Margret	2016	Integrative (trauma-)therapeutische Arbeit mit unbegleiteten minderjährigen Flüchtlingen	Gesprächspsychotherapie und Personenzentrierte Beratung	47	1	6-12	Grundlagen und Herausforderungen der integrativen Therapie mit unbegleiteten minderjährigen Flüchtlingen (UMF) werden beleuchtet. Neben einem Einblick in die Stärken des personenzentrierten Ansatzes in der Psychotherapie mit UMF wird die Bedeutung einer kultursensiblen Haltung verdeutlicht. Zudem wird der Bedarf an in der Traumatherapie bewährten Methoden anderer Therapierichtungen beschrieben. Auf der Grundlage persönlicher Erfahrungen werden folgende Methoden als hilfreich für die Stabilisierung skizziert: Psychoedukation, Entspannungsverfahren, Imaginationsverfahren, verhaltenstherapeutische Manuale, ressourcenorientierte Verfahren,

							Gestalttherapie und systemische Therapie. Nach einer Darstellung der besonderen Schwierigkeiten, die sich durch den notwendigen Einsatz von Sprach- und Kulturmittlern für die therapeutische Situation ergeben, wird exemplarisch der Verlauf einer therapeutischen Begleitung während der Clearingphase an einem Fallbeispiel aufgezeigt.
Engelsmann, Petra; Manke, Judith; Runowski, Heike	2023	Personzentrierte Haltung in Kindertagesstätten - Neue Fortbildungen für pädagogisches Fachpersonal	Gesprächspsychotherapie und Personzentrierte Beratung	54	1	32–33	Kein Abstract verfügbar
Engesser, Deborah; Maier, Lena; Mittag, Martina; Lang, Klaus; Nagel-Brotzler, Almut; Wirp, Bernhild; Kobes, Jörg; Singer, Susanne	2023	Outpatient Psychotherapy Before and After the Reform of the Psychotherapy Directive of 2017: Data from Practices with and without Psycho-Oncologic Specialty	Gesundheitswesen (Bundesverband der Ärzte des Öffentlichen Gesundheitsdienstes (Germany))	85	10	911–917	BACKGROUND: The reform of the German psychotherapy directive in 2017 resulted in several changes for non-hospital-based psychotherapists. We examined whether patients received psychotherapy following their initial consultation more frequently after the reform than before. METHODS: Using records from psychotherapy practices in a retrospective cohort study, we investigated the frequency of a psychotherapy after the patients' initial consultation. We compared a time frame of three years before and after the reform. A potential association between reform and psychotherapy received was analysed via logistic regression. RESULTS: Our analysis comprised 1548 records from 9 psychotherapy practices, consisting of 755 records before and 793 records after the reform. Before the reform, 40% (n=303) of the patients who had an initial consultation went on to receive psychotherapy. After the reform, 46% (n=360) of initial consultations were followed by psychotherapy (including acute care). The logistic regression analysis showed a

							36% increased probability of receiving psychotherapy after an initial consultation after the reform in comparison to before the reform (odds ratio 1.36 after vs. before reform, 95% confidence interval 1.09 - 1.68). CONCLUSION: Our results indicate a higher chance of receiving psychotherapy after an initial consultation after the reform compared to before the reform. Our data do not contain information as to whether the absolute number of psychotherapy appointments in the practices increased after the reform.

Erdin, Gisela	2018	Zwischen Abhängigkeit und Vereinsamung: Beziehungsgestaltung in der Heilpädagogik und Sozialpädagogik	Gesprächspsychotherapie und Personenzentrierte Beratung	49	3	145–147	Reflektiert wird über die professionelle Beziehungsgestaltung mit Menschen mit geistiger Behinderung im heil- und sozialpädagogischen Kontext auf Grundlage der Ergebnisse eines Workshops im Rahmen des GwG-Jahreskongresses 2018. Zunächst erfolgt ein kurzer Rückblick auf den im 20. Jahrhundert vollzogenen Wandel im Umgang mit Menschen mit geistiger Behinderung: Dieser entwickelte sich von einer reinen Verwahrung hin zu Betreuungsformen, die Selbstbestimmung und Teilhabe der Betroffenen fördern. Aktuelle Implikationen für die Beziehungsgestaltung, insbesondere hinsichtlich der Haltung von Heilpädagogen und Sozialpädagogen, werden angeführt.
Erdin, Gisela	2020	Personenzentrierte Heilpädagogik und ein neuer Master	Gesprächspsychotherapie und Personenzentrierte Beratung	51	1	19–21	Vorgestellt wird ein Konzept zur personenzentrierten Heilpädagogik, bei dem die Beratung und Alltagsbegleitung von Menschen mit Behinderungen unter besonderer Berücksichtigung ihres Autonomiebedürfnisses stattfinden

							und auf der Grundlage einer empathischen, wertschätzenden und authentischen Beziehungsgestaltung fuen. Im Anschluss wird ein neuer Weiterbildungsmasterstudiengang an der Alanus Hochschule in Mannheim vorgestellt, der Studierende in personenzentrierter Beratung und Gesprächsführung in der Heilpädagogik ausbilden soll.
Erdin, Gisela	2023	Sexuelle Fantasien und Wirklichkeit	Gesprächspsychotherapie und Personenzentrierte Beratung	54	2	8-12	Dieser Beitrag behandelt das Spannungsfeld aus Sehnsucht nach Erotik, Freundschaften und Sexualität und der besonderen Gefährdung von Menschen mit Assistenzbedarf (Menschen mA), Opfer von sexualisierter Gewalt zu werden. Hierbei wird insbesondere die Forderung, Menschen mA in ihren Wünschen und Bedürfnissen ernst zu nehmen, in den Mittelpunkt gestellt. Im Alltag bedeutet dies für Assistenten*innen eine große Herausforderung: Sie sollen Menschen mA sowohl in ihren erotischen Fantasien, die zur normalen sexuellen Entwicklung gehören, ernst nehmen als auch in ihren Aussagen bezüglich sexueller Begriffe, denen sie immer wieder ausgesetzt sind.
Erichev, A. N.; Kotsubinsky, A. P.; Kuznetsova, S. L.	2021	Depression as a biopsychosocial problem	Zhurnal nevrologii i psikiatrii imeni S.S. Korsakova	121	5. Vyp . 2	7-11	The article discusses the role of biological and psychological adaptive and compensatory mechanisms in the aetiology and pathogenesis of affective disorders, the relationship between the genetic characteristics of an individual, which determine vulnerability, and epigenetic mechanisms dependent on external psychosocial influences. The role of psychological factors disrupted the consistency of mental functions and the preservation of individuality that determines the psychogenesis of the disease both at the borderline and at the psychotic level is indicated. The psychoprophylactic and therapeutic role of psychotherapy is substantiated with an analysis of its influence both on the biological parameters of the brain

							and on the psychological characteristics of an individual, including an assessment of the quality of life. A comprehensive biopsychosocial approach to a spectrum of affective disorders makes a significant contribution to the development of personalized person-centered medicine, considering the phenomenological characteristics of the disease, as well as the psychological characteristics of patients and the nature of their social adaptation, which increases the effectiveness of treatment and rehabilitation of mentally ill patients.
Errázuriz, Paula; Zilcha-Mano, Sigal	2018	In psychotherapy with severe patients discouraging news may be worse than no news: The impact of providing feedback to therapists on psychotherapy outcome, session attendance, and the alliance	Journal of consulting and clinical psychology	86	2	125–139	Objective: Our objective was to assess low-cost and feasible feedback alternatives and compare them to Lambert’s OQ feedback system. We also studied patient, therapist, and process characteristics that could moderate the effect of feedback on outcome, session attendance, and alliance. Method: A total of 547 patients, 75% female, average age 41 (SD = 13), 95% Latino, treated in an outpatient individual psychotherapy setting in Chile were randomly assigned to five feedback conditions: no feedback, feedback on symptomatology, feedback on the alliance, feedback on both symptomatology and alliance, and Lambert’s OQ progress feedback report. The measures included the Outcome Questionnaire and the Working Alliance Inventory. We also had follow-up interviews with therapists. Results: We found through multilevel modeling that feedback had no effect on outcome, session attendance, and alliance. Contrary to previous findings, these results were maintained even when focusing only on patients “not-on-track.” However, patients’ former psychiatric hospitalization history and baseline severity, combined with lack of progress, significantly moderated the impact of feedback. For this

							more dysfunctional population, “positive feedback” (i.e., low symptomatology) to therapists had a positive impact on therapy outcome, while “negative feedback” (i.e., high symptomatology) had a negative impact. Conclusions: Providing feedback to therapists without offering them tools to improve treatment may be ineffective and even be detrimental. This may be especially the case for patients who suffer more severe mental health issues and whose therapists receive mostly discouraging news as feedback. Erskine, Richard	2018	Lebensskripts und Bindungsmuster : ihre theoretische Integration und die therapeutischen Folgerungen	Zeitschrift fr Transaktionsanalyse	35	1	5–30	Es werden die Bindungsmuster "sicher, ngstlich/ambivalent, vermeidend, desorganisiert und isoliert" beschrieben, zur Skripttheorie in Beziehung gesetzt und es wird auf ihre psychotherapeutischen Implikationen hingewiesen. Ursprnglich beschrieb Eric Berne das Lebensskript als entstanden aus den primren Dramen und impliziten Entwrfen in der Suglingszeit und frhen Kindheit. John Bowlbys Bindungstheorie und die weiterfhrende Forschung ermöglichen eine theoretische Integration der Skripttheorie und betonen die Notwendigkeit, den Fokus in der Psychotherapie auf die Entwicklung zu legen.
Ertekin Pinar, Sukran; Daglar, Gulseren; Duran Aksoy, Ozlem	2022	The effect of stress management training on perceived stress, anxiety and hopelessness levels of women	Journal of obstetrics and gynaecology : the journal of the Institute of Obstetrics and Gynaecology	42	1	17–22	The aim of this study was to investigate the effect of stress management training on the perceived stress, anxiety and hopelessness levels of women with high-risk pregnancy. The sample of this experimental study consisted of 206 high-risk pregnant women (intervention = 103; control = 103). Data were collected using a Personal Information Form, the Perceived Stress Scale, the Beck Hopelessness Scale and the State-Trait Anxiety Inventory. In the second follow-up after the training, there was a statistically significant difference amongst the

		with high-risk pregnancy					Perceived Stress Scale, Beck Hopelessness Scale and State-Trait Anxiety Inventory mean scores in the intervention and control groups ($p < .05$). Perceived stress scores of the control group who did not receive training during discharge increased. The state and trait anxiety scores and hopelessness scores of the intervention group received training decreased compared with the control group.IMPACT STATEMENTWhat is already known on this subject? Mental problems such as anxiety and stress are more common in high-risk pregnancies compared with healthy pregnancies.What do the results of this study add? After the training 51.4% of women in the intervention group, 75.7% of women in the control group had stress. The state and trait anxiety and hopelessness scores of the intervention group having training decreased compared to the control group.What are the implications of these findings for clinical practice and/or further research? Health professionals should provide stress management training in high-risk pregnant women to reducing perceived stress, anxiety and hopelessness levels.
Estrada, Rita	2021	Listen and You Will See the Person Through the Dementia	Journal for person-oriented research	7	2	88-97	Dementia is an ever-increasing health and social problem, with a growing number of people being affected worldwide. As dementia progresses, dependency on others increases, requiring the presence of caregivers. Caregivers tend to focus on the diagnosis itself - dementia - which makes it difficult to see the person in their uniqueness. The person is there, and can be seen by listening, which requires time and communication skills. The voices of older adults living with several types of dementia, collected while working as a psychologist in a nursing home, are presented in the first person to bring forward the person they are. These excerpts of

						interactions illustrate the basic psychological need of relatedness, which is built through interaction, stories, and touch, and the needs of competence and autonomy. The framework of this paper encompasses validation therapy, person-centered care, and self-determination theory. Two conclusions emerge: Seeing the person through the dementia enables an adequate psychological assessment and a helpful supportive psychotherapy, and it also makes us acknowledge and help satisfy the three basic psychological needs of relatedness, competence, and autonomy.
Estrellado, Jan E.; Felipe, Lou Collette S.; Celestial, Jeannie Estella		Colonial mentality and psychological flexibility among Filipinx Americans	Asian American Journal of Psychology	13	1	While the concept of colonial mentality (CM; David & Okazaki, 2006a) has been well examined in the literature, little is understood about addressing CM in a clinical setting. The aim of this study is to examine a relationship between CM and psychological flexibility (PF; Hayes et al., 2013), with the hope of establishing acceptance and commitment therapy (ACT) as a clinically relevant theoretical orientation for addressing CM. Filipinx American participants (N = 856) completed online questionnaires regarding CM and PF. The study used a series of linear regressions to understand the predictive relationship between CM and PF. Results of the study suggest that there is a relationship between CM and PF, although the size of the effects was small. As expected, higher levels of CM were related to lower levels of PF. Higher levels of physical characteristics on the Colonial Mentality Scale (CMS; David & Okazaki, 2006b) predicted higher levels of cognitive fusion. Participants that endorsed higher levels of within-group discrimination also reported higher levels of experiential avoidance. Higher scores of cultural/ethnic inferiority predicted higher levels of self-as-content. A predictive relationship

							was established between CM and PF, suggesting that the concept of PF and ACT may be clinically relevant when working with the Filipinx population. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Etherington, Kim	2017	Practitioner research in counselling and psychotherapy: the power of example, edited by Liz Bondi and Judith Fewell, London, United Kingdom, Palgrave, 2016, 230 pp., £24.99 (paperback), ISBN 978113739029-5	Couns and Psychother Res (Counselling and Psychotherapy Research)	17	1	53–54	
Etingen, Bella; Smith, Bridget M.; Zeliadt, Steven B.; Kaitz, Jenesse E.; Barker, Anna M.; Hyde, Justeen K.; Fix, Gemmae M.; Reed, David E. 2nd; Anderson, Ekaterina; Hogan, Timothy	2023	VHA Whole Health Services and Complementary and Integrative Health Therapies: a Gateway to Evidence-Based Mental Health Treatment	Journal of general internal medicine	38	14	3144–3151	BACKGROUND: Engagement in evidence-based psychotherapy (EBP) among veterans with behavioral health conditions is often low. The Veterans Health Administration (VHA) is implementing a "Whole Health (WH)" system of care, to identify veteran personal health goals, align care with those goals, and offer services designed to engage and empower veterans to achieve well-being. OBJECTIVE: To examine the relationship between veteran WH utilization and subsequent engagement in EBP. DESIGN: Retrospective analysis of VHA administrative records from 18 facilities implementing WH. SUBJECTS: Veterans (n = 265,364) with a diagnosis of depression, post-traumatic stress disorder

P.; Bokhour, Barbara G.						<p>(PTSD), and/or anxiety who had a mental healthcare encounter but no EBP use in fiscal year (FY) 2018. Among this cohort, 33,146 (12.5%) began using WH in FY2019. MAIN MEASURES: We examined use of an EBP for depression, anxiety, and/or PTSD within 1 year of the index date of WH use compared to use of an EBP anytime during FY2019 for veterans not identified as using WH. We used multiple logistic regression to examine the association between veteran WH use and EBP engagement. KEY RESULTS: Approximately 3.0% (n = 7,860) of the veterans in our overall cohort engaged in an EBP in the year following their index date. Controlling for key demographic, health, and utilization variables, WH users had 2.4 (95% CI: 2.2-2.5) times higher odds of engaging in an EBP the following year than those with no WH utilization. Associations between utilization of specific WH services (vs. no utilization of that service) and engagement in an EBP in the subsequent year ranged from 1.6 (95% CI: 1.0-2.6) to 3.5 (95% CI: 3.2-3.9) across the different types of WH services used. CONCLUSIONS: WH use was associated with increased engagement in EBPs among veterans with depression, anxiety, and/or PTSD. Future interventions intended to promote veteran engagement in EBPs may benefit from leveraging WH services and therapies.</p>
Faerstein, Ian; Levenson, Hanna; Lee, Alexandra C.	2016	Validation of a fidelity scale for accelerated-experiential dynamic psychotherapy	Journal of Psychotherapy Integration	26	2	<p>[Correction Notice: An Erratum for this article was reported in Vol 27(2) of Journal of Psychotherapy Integration (see record 2017-16478-001). In the article, the name of Alexandra C. Lee was not included in the article. The online version of this article has been corrected.] This study sought to investigate the psychometric properties of a self-report measure of therapist fidelity to accelerated-experiential dynamic</p>

							<p>psychotherapy (AEDP). Subjects consisted of 2 samples: (a) 249 therapists (participants) who completed the measure before and after a 5-day AEDP training course, and (b) 13 AEDP trainers who completed the measure at a single point in time. The AEDP Fidelity Scale (AEDP-FS) consists of 22 items describing therapist behaviors considered essential to AEDP, each of which is rated separately for knowledge and competence. Results suggest that the AEDP-FS has promising indications of being a valid self-report measure of AEDP proficiency. Specifically, AEDP trainers reported significantly higher AEDP-FS scores than participants; participants with more AEDP experience reported significantly higher pretest scores than participants with less AEDP experience; and participants' scores increased after training. In 2 multivariate statistical analyses (PCA and CFA), 3 factors emerged that are consistent with the scale's theoretical base. Discriminant validity was suggested by 2 additional multivariate statistical analyses (principal component analysis [PCA] and confirmatory factor analysis [CFA]) that found a majority of AEDP-FS items load onto a different factor than items measuring general psychodynamic techniques. However, although the PCAs yielded relatively distinct factors, the CFAs failed to yield acceptable goodness of fit indices. Overall these findings indicate that with some further refinements the AEDP-FS may be a useful tool for describing essential AEDP interventions, investigating outcome in AEDP, and training AEDP therapists. (PsycINFO Database Record (c) 2017 APA, all rights reserved)</p>
Faija, Cintia L.; Tierney, Stephanie;	2017	The role of pride in women with anorexia	Psychology and psychotherapy	90	4	567–585	<p>OBJECTIVE Theory and clinical literature suggest that pride may play an important role in the maintenance of restrictive eating</p>

<p>Gooding, Patricia A.; Peters, Sarah; Fox, John R. E.</p>		<p>nervosa: A grounded theory study</p>				<p>disorders. A grounded theory study explored experiences of, and reflections on, pride among women with a current or past diagnosis of anorexia nervosa.</p> <p>DESIGN This is a qualitative study using grounded theory.</p> <p>METHOD Semistructured interviews were conducted with 21 women recruited from an eating disorder unit in England, and from a UK self-help organization. Grounded theory from a constructivist lens was used. Analysis involved coding, constant comparison, and memo-writing.</p> <p>RESULTS Pride evolves over the course of anorexia nervosa. Two overarching conceptual categories were identified: 'pride becoming intertwined with anorexia' and 'pride during the journey towards recovery'. These categories encompassed different forms of pride: 'alluring pride', 'toxic pride', 'pathological pride', 'anorexia pride', 'shameful pride', 'recovery pride', and 'resilient pride'. Initially, pride contributed to self-enhancement and buffered negative emotions. As the condition progressed, pride became a challenge to health and interfered with motivation to change. During recovery, perceptions of pride altered as a healthy approach to living ensued.</p> <p>CONCLUSIONS The evolving nature of pride plays a central role in development, maintenance, and treatment of anorexia nervosa. Understanding of pride and its role in psychotherapeutic work with this client group may increase motivation to change and promote recovery. Future work should investigate whether tackling pride in eating disorders increases treatment efficacy and reduces the risk of relapsing.</p>
---	--	---	--	--	--	--

							<p>PRACTITIONERS POINTS</p> <p>Pride associated with anorexia appeared to evolve in nature. During early stages of the eating disorder, it stopped people from seeking help. Later on, it prevented them from seeing pride in healthy domains of life (outside anorexia). Over time, pride in anorexia became an overwhelming emotion that interfered with motivation to change. It is important for practitioners to assess and discuss pride in anorexia and its evolving nature during treatment. Understanding of pride and its role in psychotherapeutic work with this client group may increase motivation to change and promote recovery.</p>
Falicov, Celia; Nakash, Ora; Alegría, Margarita	2021	Centering the Voice of the Client: On Becoming a Collaborative Practitioner with Low-Income Individuals and Families	Family process	60	2	670–687	<p>Despite current interest in collaborative practices, few investigations document the ways practitioners can facilitate collaboration during in-session interactions. This investigation explores verbatim psychotherapy transcripts to describe and illustrate therapist's communications that facilitate or hinder centering client's voice in work with socioeconomically disadvantaged populations. Four exemplar cases were selected from a large intervention trial aimed at improving shared decision making (SDM) skills of psychotherapists working with low-income clients. The exemplar cases were selected because they showed therapist's different degrees of success in facilitating SDM. Therapist's verbalizations were grouped into five distinct communicative practices that centered or de-centered the voice of clients. Communication practices were examined through the lens of collaborative approaches in family therapy. The analysis suggests that cross-fertilization between SDM and family-oriented collaborative and critical approaches shows promise to illuminate and enhance the challenging road from</p>

							<p>clinician-led to client-led interactions. This paper also stresses the importance of incorporating relational intersectionality with individuals and families who may not feel entitled to express their expectations or raise questions when interacting with authority figures.</p>
<p>Falkenström, Fredrik; Solomonov, Nili; Rubel, Julian</p>	2020	<p>Using Time-Lagged Panel Data Analysis to Study Mechanisms of Change in Psychotherapy Research: Methodological Recommendations</p>	<p>Couns and Psychother Res (Counselling and Psychotherapy Research)</p>	20	3	435–441	<p>The introduction of novel methodologies in the past decade has advanced research on mechanisms of change in observational studies. Time-lagged panel models allow to track session-by-session changes and focus on within-patient associations between predictors and outcomes. This shift is crucial, as change in mechanisms inherently takes place at a within-patient level. These models also enable preliminary casual inferences, which can guide the development of effective personalized interventions that target mechanisms of change, used at specific treatment phases for optimal effect. Given their complexity, panel models need to be implemented with caution, as different modeling choices can significantly affect results and reduce replicability. We outline three central methodological recommendations for use of time-lagged panel analysis to study mechanisms of change: a) Taking patient-specific effects into account, separating out stable between-person differences from within-person fluctuations over time; b) properly controlling for autoregressive effects; c) considering long-term time-trends. We demonstrate these recommendations in an applied example examining the session-by-session alliance-outcome association in a naturalistic psychotherapy study. We present limitations of time-lagged panel analysis and future directions.</p>

Fallon, Veronica T.; Rubenstein, Samantha; Warfield, Rebecca; Ennerfelt, Hannah; Hearn, Brenna; Leaver, Echo	2020	Stress reduction from a musical intervention	Psychomusicology: Music, Mind, and Brain	30	1		Research suggests that music can affect mood and physiological states (Elliott, Polman, & McGregor, 2011; Thoma et al., 2013). The extant literature has mainly focused on long-term changes in self-report measures resulting from several sessions of music intervention (but see Jiang, Zhou, Rickson, & Jiang, 2013 and Pelletier, 2004 for review). The purpose of this study was to expand the previous work in three major ways. First, the stress-reducing effects of music listening versus musical improvisation on a xylophone were compared. Second, psychophysiological measures of stress were utilized in addition to self-report measures. Third, stress reduction effects were measured in one session. A total of 105 participants completed a stressor task and were then assigned to one of three recovery conditions: control (CG), music listening (ML), or music improvisation (MI). The ML and MI groups were expected to exhibit greater stress reduction (evidenced by behavioral and physiological measures) than the CG. Self-report and skin conductance (electrodermal activity; EDA) measures were used to assess response during the stressor task and recovery session. Results indicated that participants exhibited a significant increase in stress response as a result of the stressor task. Although self-report measures indicated that mood improved during the recovery session, the MI group exhibited only differential effects for levels of satisfaction. The physiological data showed greater stress reduction for the ML condition as compared with the CG and MI group. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Fana, Michael; Chao, Shing;	2022	Rituximab for prevention of strokes in	Clinical neurology and neurosurgery	215		107199	Rheumatoid arthritis (RA) is an autoimmune disorder which manifests as inflammation of the synovial joints alongside extra-articular involvement. Uncommonly,

Katramados, Angelos M.		cerebral rheumatoid vasculitis					patients may develop vasculitis of small and medium-sized blood vessels, formally diagnosed as systemic rheumatoid vasculitis (SRV). In particularly rare cases, patients may develop a subtype of SRV known as cerebral rheumatoid vasculitis (CRV) which manifests in patients as stroke. To date, no formal recommendations or guidelines have been established for treatment and prevention of CRV-induced stroke besides experiential therapy with various immunomodulators. Here, we describe the utility of Rituximab in addition to steroids for prevention of stroke in our patient with evidence of multiple CRV-induced strokes with excellent recovery of post-stroke symptoms and remission of new onset cerebral vasculitis processes.
Fankhaenel, Thomas; Mueller, Anna-Maria; Frese, Thomas	2021	General Practice Patients' Readiness to be Treated With Brief Intervention to Reduce Alcohol Consumption: A Cross-Sectional Study With Between-Subject Design	Alcohol and alcoholism (Oxford, Oxfordshire)	56	3	291–298	AIMS: To treat excessive alcohol consumption, general practices (GPs) are recommended to use non-directive implementation strategies. Directive implementation, however, may be perceived by general practice patients as something positive because of possibly indicating higher GP engagement and a more consistent treatment. In our study, we aimed to assess the readiness of patients to be treated with BI in the hypothetical event of excessive alcohol consumption either by a GP using non-directive recommendations according to WHO or by a GP using directive instructions. Additionally, we assessed the patients' dispositional readiness to disclose alcohol-associated personal information, termed alcohol consumption self-disclosure, in order to analyze its influence on their readiness to be treated with brief intervention (BI). METHODS: When consulting their GP, a convenience sample of general practice patients was asked by questionnaire. By means of a between-subject design, they were asked for the readiness to be treated

							either with non-directive BI or with directive BI. Repeated-measure ANCOVA was used to analyze the main- and interaction effects. RESULTS: A sample of 442 general practice patients preferred the non-directive BI, $F(1, 423) = 5.56, P < 0.05$. We found moreover a two-way interaction between implementation and alcohol consumption self-disclosure, $F(1, 423) = 18.89, P < 0.001$, showing that only patients with low self-disclosure preferred the non-directive BI, $t(428) = 3.99, P < 0.001$. CONCLUSIONS: Future research should investigate the reasons for the patients' preference for the non-directive BI and may develop strategies to overcome the possibly low readiness of general practice patients to be treated with BI.
Farber, Barry A.	2020	Disclosure, concealment, and dishonesty in psychotherapy: A clinically focused review	Journal of clinical psychology	76	2	251–257	This issue of Journal of Clinical Psychology: In Session focuses on the nature and consequences of psychotherapy clients' disclosures, secrets, and dishonesty, with a particular emphasis on the ways in which therapists can best facilitate greater and more honest disclosure. This introduction to this issue reviews the growing theoretical and empirical literature on the frequency, types, motives, and consequences of client and therapist dishonesty (broadly defined); it also reviews the contributions within this issue, noting the welcome focus of the majority of these papers on the nature of client dishonesty in specific disorders (e.g., eating disorders; substance abuse) and/or specific clinical settings (e.g., prisons). Taken together, these papers speak to the ways that therapists may tailor their clinical interventions to match the specific ways that dishonesty manifests in different clinical populations.
Farber, Barry A.; Suzuki, Jessica	2018	Positive regard and	Psychotherapy	55	4	411–423	This article meta-analytically reviews the research on the association between therapist positive regard (PR) and

Y.; Lynch, David A.		psychotherapy outcome: A meta-analytic review					treatment outcome. The history of the construct of unconditional PR in client-centered theory and the efforts to clearly operationalize and measure this construct are reviewed. Several clinical examples are presented. The updated meta-analysis, which features expanded inclusion criteria and a larger number of studies (k = 64) than previous analyses, yielded a small positive association between PR and treatment outcome, $g = .28$. To control for the repeated use of data sets and study samples within the database, a multilevel meta-analysis was adopted that indicated a stronger relation between PR and clinical outcome ($g = 0.36$). These analyses support PR's standing as a significant component of the therapy relationship that leads to improved clinical outcomes. The article concludes with limitations of the research, patient contributions, diversity considerations, and recommendations for using PR in practice. Farmer, Courtney C.; Rossi, Fernanda S.; Michael, Elizabeth M.; Kimerling, Rachel	2020	Psychotherapy Utilization, Preferences, and Retention among Women Veterans with Post-traumatic Stress Disorder	Women's health issues : official publication of the Jacobs Institute of Women's Health	30	5	366–373	BACKGROUND: Psychotherapy is the gold standard treatment for post-traumatic stress disorder (PTSD), yet psychotherapy use and retention among veterans is low. Little is known about the barriers to care and factors associated with women veterans' PTSD psychotherapy use and retention. Using a nationally representative sample of 986 women Veterans Health Administration primary care users with PTSD and a perceived need for mental health care, we examined 1) the proportion of women who used psychotherapy, 2) retention in psychotherapy among women who used any psychotherapy, and 3) individual factors related to psychotherapy use and retention. METHODS: Women completed a survey on their mental health care experiences. Outpatient mental health care use in the

							<p>year before the survey was obtained from Veterans Health Administration administrative data. RESULTS: Most women (79.1%) used psychotherapy, and 41.7% of those women had a minimal therapeutic dose of psychotherapy (≥ 8 visits). Mental health diagnostic comorbidity and being African American/Black or identifying as neither African American/Black nor White were significantly associated with higher psychotherapy use. Mental health diagnostic comorbidity, exposure to military sexual trauma, and receiving treatment aligned with gender-related and group-related preferences were associated with higher psychotherapy retention. Being a parent was associated with lower retention. CONCLUSIONS: Although a significant proportion of women veterans with PTSD are using psychotherapy, retention is enhanced when women are able to obtain treatment aligned with their preferences. Thus, efforts to promote patient-centered, shared decisions regarding mental health treatment options could increase the efficacy and efficiency of treatment for PTSD among women.</p>
Fasbender, Jana; Sachse, Rainer	2021	Beziehungsgestaltung in der Klrungsorientierten Verhaltenstherapie	Verhaltenstherapie und Verhaltensmedizin	42	3	162-176	<p>In der Klrungsorientierten Verhaltenstherapie (KOV) werden neben den Beziehungsvariablen Empathie usw. spezifische Strategien der Beziehungsgestaltung entwickelt. Dies ist eine sogenannte "komplementre Beziehungsgestaltung" zu den zentralen Beziehungsmotiven. Es werden die relevanten Beziehungsmotive beschrieben und die dazu gehenden komplementren Strategien aktiver Beziehungsgestaltung.</p>
Fassbinder, Eva; Schweiger, Ulrich; Martius, Desiree; Brande Wilde,	2016	Emotion Regulation in Schema Therapy and Dialectical	Frontiers in psychology	7		1373	<p>Schema therapy (ST) and dialectical behavior therapy (DBT) have both shown to be effective treatment methods especially for borderline personality disorder. Both, ST and DBT, have their roots in cognitive behavioral therapy and aim at helping patient to deal with emotional</p>

Odette; Arntz, Arnoud		Behavior Therapy					<p>dysregulation. However, there are major differences in the terminology, explanatory models and techniques used in the both methods. This article gives an overview of the major therapeutic techniques used in ST and DBT with respect to emotion regulation and systematically puts them in the context of James Gross' process model of emotion regulation. Similarities and differences of the two methods are highlighted and illustrated with a case example. A core difference of the two approaches is that DBT directly focusses on the acquisition of emotion regulation skills, whereas ST does seldom address emotion regulation directly. All DBT-modules (mindfulness, distress tolerance, emotion regulation, interpersonal effectiveness) are intended to improve emotion regulation skills and patients are encouraged to train these skills on a regular basis. DBT assumes that improved skills and skills use will result in better emotion regulation. In ST problems in emotion regulation are seen as a consequence of adverse early experiences (e.g., lack of safe attachment, childhood abuse or emotional neglect). These negative experiences have led to unprocessed psychological traumas and fear of emotions and result in attempts to avoid emotions and dysfunctional meta-cognitive schemas about the meaning of emotions. ST assumes that when these underlying problems are addressed, emotion regulation improves. Major ST techniques for trauma processing, emotional avoidance and dysregulation are limited reparenting, empathic confrontation and experiential techniques like chair dialogs and imagery rescripting.</p>
Fauerbach, James A.; Gehrke,	2020	Cognitive Behavioral Treatment for	Archives of physical	101	1S	S16-S25	<p>OBJECTIVE: (1) To evaluate the feasibility of conducting a randomized controlled trial (RCT) of the Safety, Meaning, Activation and Resilience Training (SMART) intervention vs</p>

<p>Amanda K.; Mason, Shawn T.; Gould, Neda F.; Milner, Stephen M.; Caffrey, Julie</p>		<p>Acute Posttrauma Distress: A Randomized, Controlled Proof-of- Concept Study Among Hospitalized Adults With Burns</p>	<p>medicine and rehabilitation</p>			<p>nondirective supportive psychotherapy (NDSP) in an acutely hospitalized adult survivor of burn injury sample; and (2) to assess the preliminary effect of SMART on acute stress disorder (ASD), posttraumatic stress disorder (PTSD), and major depressive disorder (MDD) symptom reduction as secondary prevention. DESIGN: Proof-of-concept, parallel group RCT design. SETTING: Regional burn center. PARTICIPANTS: Acutely injured, hospitalized adult survivors of burn injury (N=50) were randomly assigned to SMART (n=28) or nondirective supportive psychotherapy (n=22). Due to dropout and missing data, final sample size was 40, SMART (n=21) and nondirective supportive psychotherapy (n=19). INTERVENTIONS: SMART is a manualized, 4-session cognitive behavioral therapy-based psychological intervention targeting ASD, PTSD, and MDD symptoms. NDSP is a manualized, 4-session protocol. MAIN OUTCOME MEASURES: Davidson Trauma Scale ([DTS]; diagnostic proxy for ASD and PTSD; clinical cutoff=40, with higher score=higher severity) and the Patient Health Questionnaire-9 ([PHQ-9]; diagnostic proxy for MDD; clinical cutoff=10, with higher score=higher severity) at pretreatment, immediate posttreatment, and 1 month posttreatment. RESULTS: At baseline, median DTS scores and PHQ-9 scores were above clinical cutoffs and did not differ across groups. At 1 week and 1 month posttreatment, median DTS and PHQ-9 scores were beneath clinical cutoffs in the SMART group; scores remained above clinical cutoffs in the NDSP group at these time points. CONCLUSIONS: It is feasible to conduct an RCT of SMART in hospitalized adult survivors of burn injury. SMART has the potential to yield clinically</p>

							significant outcomes. Additional studies are needed to replicate and extend these findings.
Fava, Giovanni A.; Tomba, Elena	2010	New modalities of assessment and treatment planning in depression: the sequential approach	CNS drugs	24	6	453-465	The sequential model of treatment for depression, i.e. the use of psychotherapy in patients who have remitted from a major depressive disorder after a course of pharmacotherapy, is an intensive two-stage approach that derives from the awareness that one course of treatment is unlikely to provide a solution to all the symptoms of patients. The aim of the sequential approach is to provide different types of treatment for as long as considered necessary in different phases of illness as determined by repeated assessments. The treatment strategies are chosen on the basis of the symptoms identified and not as predefined options. The sequential model emphasizes consideration of subclinical and residual symptomatology according to the organizing principles of macro-analysis (a relationship between co-occurring symptoms and problems is established on the basis of where treatment should commence in the first place). Diagnostic endpoints (i.e. DSM diagnoses), the customary guidance of treatment planning, are replaced by conceptualization of disorders as 'transfer stations', which are amenable to longitudinal verification and modification. The aim of this systematic review was to survey the literature concerned with the sequential approach to the treatment of depression. Randomized controlled trials were identified using MEDLINE and a manual search of the literature. In seven of the eight studies that were identified, the sequential use of pharmacotherapy and psychotherapy was found to improve long-term outcome after termination of treatment compared with clinical management and treatment as usual. Nevertheless, data on this approach

							are limited and more studies are necessary for detailing the various clinical steps associated with it. The sequential approach calls for a re-assessment of the design of comparative clinical trials. It allows randomization of patients who are already in treatment and assignment of them to treatment alternatives according to stages of development of their illness and not simply to disease classification. The model is thus more in line with the chronicity of mood disorders compared to the standard randomized controlled trial, which is based on the acute disease model.
Fazeli, Pariya L.; Turan, Janet M.; Budhwani, Henna; Smith, Whitney; Raper, James L.; Mugavero, Michael J.; Turan, Bulent	2017	Moment-to-moment within-person associations between acts of discrimination and internalized stigma in people living with HIV: An experience sampling study	Stigma and Health	2	3	216–228	Internalized stigma related to HIV is associated with poorer outcomes for people living with HIV (PLWH). However, little is known about the association between experiences of daily acts of discrimination by others and the activation of internalized stigma, including factors that may moderate this association. One hundred 9 men living with HIV responded to experience sampling method (ESM) questions 3 times a day for 7 days via smart-phones. ESM questions included experiences of recent acts of discrimination, internalized HIV stigma, avoidance coping with HIV, and recent social support. We also administered several traditional questionnaire measures assessing psychosocial constructs. In hierarchical linear modeling analyses controlling for age, race, socioeconomic status, and time on antiretroviral therapy, experiencing discrimination predicted internalized stigma within persons. Individuals higher on attachment-related avoidance, attachment-related anxiety, avoidance coping, perceived community stigma, and helplessness, and individuals lower on social support had stronger associations between discrimination and current internalized stigma. Similarly, results from 2 state

							<p>moderator variables supported our trait analyses: State-level (ESM) social support and avoidance coping were significant moderators. Thus, when PLWH experience incidents of discrimination due to HIV, this may lead to increased feelings of internalized stigma. We extend the literature by demonstrating that the associations between experienced and internalized stigma are not just at the generalized trait level, but also occur at the state level, accounting for within-person variability. Results provide implications for interventions aiming to modify maladaptive interpersonal traits as well as interventions to increase social support to reduce the impact of discrimination on PLWH. (PsycINFO Database Record (c) 2019 APA, all rights reserved)</p>
Feeney, Judith A.; Fitzgerald, Jennifer	2022	Autonomy-connection tensions, stress, and attachment: The case of COVID-19	Current opinion in psychology	43		18–23	<p>The COVID pandemic, and actions taken by governments worldwide to deal with it, have placed stress on couple relationships. Reports from many countries have documented substantial increases in relationship difficulties, conflict, and violence. We propose that issues concerning autonomy and connection are central to these problems, particularly as couples face changing situations with regard to lockdowns, social distancing, and border closures. We further propose that a fruitful approach to understanding these difficulties comes from integrating attachment theory with key concepts of stress and coping theories. Based on these principles and concepts, emotionally focused couples therapy (EFT) offers guidelines to help couples navigate the multiple stressors associated with the pandemic. Fehkührer, Sonja; Humer, Elke; Kaltschik,	2023	Young People and the Future: School	Healthcare (Basel, Switzerland)	11	16		<p>The COVID-19 pandemic resulted in enormous changes in everyday life and numerous burdens for adolescents. This pilot study focused on how young people look to the</p>

<p>Stefan; Pieh, Christoph; Probst, Thomas; Diestler, Gertraud; Jesser, Andrea</p>		<p>Students' Concerns and Hopes for the Future after One Year of COVID-19 in Austria- Findings of a Mixed-Methods Pilot Study</p>				<p>future in the face of these burdens. Responses to two open-ended questions on concerns and hopes for the future that were part of a larger online survey on the mental health of school students in Austria were analyzed using qualitative content analysis. Subsequently, differences in the experiences of boys and girls, young people with and without a migration background and psychologically stressed and non-stressed young people were examined by applying a mixed-methods approach. Data collection took place from 3 February to 28 February 2021. From a total survey sample of 3052 adolescents aged 14-20, a representative sample according to gender and migration background (N = 500) was drawn. Qualitative content analysis revealed several areas of concern about the future, including school-related concerns, concerns about the further development of the pandemic and the associated restrictions, concerns related to a lack of locus of control, health-related concerns and concerns about social relationships. The analysis also indicated young people's greatest hopes for the future, such as hopes related to further pandemic development, hopes regarding major life goals, school, social relationships and health. Young people's experiences differ according to gender, migration background and the extent of psychological distress. This study contributes to research on the psychological well-being of adolescents during the pandemic and provides important insights into the subjective experience of young people. It aims to gain a more comprehensive understanding of the concerns and hopes for the future of young people in a time marked by various challenges. The results of the study should be used to develop ideas for measures, such as the expansion of school psychological</p>

							services and low-threshold support services for students, such as school social work and counseling.
Feldman, Jeffrey B.	2020	The Rhythmic Finger Focus Hypnotic Technique: Multilevel Application of Ericksonian Utilization	The American journal of clinical hypnosis	62	4	409-426	This paper presents a hypnotic technique that starts with a suggested focus on one's fingertips, and movement of the hands in a self-determined rhythm. The technique involves the use of the utilization principle of Milton Erickson in multiple ways. This includes utilizing psychomotor agitation characteristic of psychophysiological arousal, directing it toward movement that generates the sensations upon which to focus. It utilizes the sensitivity of the fingertips, the high degree of representation of the hands in the somatosensory cortex, and the tendency of the brain to orient to novelty to help facilitate focused absorption. It generates counter stimulation for pain management, and emotionally self-soothing tactile sensations. The technique is further designed to activate and utilize prior sensorimotor learning and sensory experiences associated with the hands to access feelings of mastery, creativity, flow, self-efficacy, and other positive emotional experiences. It is hypothesized that multisystem coherence is generated through activating prior positive motor, behavioral and affective experiential learning. It is further hypothesized that the rhythmic movement and sensory input simultaneously generated by and processed in the right and left hemispheres, entrains the hemispheres toward greater sympathetic/parasympathetic balance.
Feldthusen, Caroline; Dean, Elizabeth; Forsblad-d'Elia, Helena;	2016	Effects of Person-Centered Physical Therapy on	Archives of physical medicine and rehabilitation	97	1	26-36	OBJECTIVE To examine effects of person-centered physical therapy on fatigue and related variables in persons with rheumatoid arthritis (RA). DESIGN

<p>Mannerkorpi, Kaisa</p>		<p>Fatigue-Related Variables in Persons With Rheumatoid Arthritis: A Randomized Controlled Trial</p>				<p>Randomized controlled trial.</p> <p>SETTING Hospital outpatient rheumatology clinic.</p> <p>PARTICIPANTS Persons with RA aged 20 to 65 years (N=70): intervention group (n=36) and reference group (n=34).</p> <p>INTERVENTIONS The 12-week intervention, with 6-month follow-up, focused on partnership between participant and physical therapist and tailored health-enhancing physical activity and balancing life activities. The reference group continued with regular activities; both groups received usual health care.</p> <p>MAIN OUTCOME MEASURES Primary outcome was general fatigue (visual analog scale). Secondary outcomes included multidimensional fatigue (Bristol Rheumatoid Arthritis Fatigue Multi-Dimensional Questionnaire) and fatigue-related variables (ie, disease, health, function).</p> <p>RESULTS At posttest, general fatigue improved more in the intervention group than the reference group (P=.042). Improvement in median general fatigue reached minimal clinically important differences between and within groups at posttest and follow-up. Improvement was also observed for anxiety (P=.0099), and trends toward improvements were observed for most multidimensional aspects of fatigue (P=.023-.048), leg strength/endurance (P=.024), and physical activity (P=.023). Compared with the reference group at follow-up, the intervention group improvement was observed for leg strength/endurance (P=.001), and the trends toward improvements persisted for physical (P=.041) and living-related (P=.031) aspects</p>
---------------------------	--	--	--	--	--	--

							of fatigue, physical activity (P=.019), anxiety (P=.015), self-rated health (P=.010), and self-efficacy (P=.046). CONCLUSIONS Person-centered physical therapy focused on health-enhancing physical activity and balancing life activities showed significant benefits on fatigue in persons with RA.
Fereydouni, Shapour; Forstmeier, Simon	2022	An Islamic form of logotherapy in the treatment of depression, anxiety and stress symptoms in university students in Iran	Journal of religion and health	61		139–157	Previous research demonstrated that spiritually sensitive psychotherapy is an effective treatment for clients with depression or anxiety, with outcomes equivalent to secular control interventions. The goal of this study was to evaluate the efficacy of spiritually sensitive logotherapy intervention in the treatment of depression, anxiety, and stress symptoms in university students in Iran. Sixty students with elevated depression symptoms (Beck Depression Inventory II, BDI-II, 22 or greater) were randomly assigned to either a twelve-session group logotherapy programme or a control group. Results showed that spiritually sensitive logotherapy significantly reduced depression, anxiety, and stress, and significantly more so than in the control group (e.g. interaction effect for BDI-II: $F = 56.8$, $p < 0.001$, with a large effect size).
Fernández, Olga; Altimir, Carolina; Reinel, Mahaira; Duarte, Javiera; Krause, Mariane	2023	"I am strong and I can get on with my life": The subjective experience of recovery of patients treated for depression	Psychotherapy research : journal of the Society for Psychotherapy Research	33	5	625–639	OBJECTIVE: : The aim of the study was to characterize the subjective experience of recovery from depression based on the perspective of those who suffer from it. METHOD: : Forty participants from two South American countries, who had been or were currently being treated for depression, took part in semi-structured and in-depth interviews. Most participants were female (78%), with ages ranging from 22 to 63 years. Interviews were analyzed using Grounded Theory, creating a hierarchy of categories that represent participants' experience of recovery. The categories were subsequently organized around an emergent central phenomenon. RESULTS: :

							<p>"Transformation of the experience of the depressed self" was constructed as the main phenomenon that accounts for the subjective understanding of recovery. This transformation consists in an increase in self-acceptance, self-appreciation, and auto-biographical contextualization, coupled with an increase in agency and empowerment. CONCLUSION: : Recovery is experienced as a multidimensional process that goes beyond the absence of symptoms. Change is experienced as a result of active self-management and commitment. The relevance of person-centered perspectives and their subjectivity for managing depression is discussed.</p>
<p>Fernández-Rodríguez, Concepción; Loredo-Martínez, Víctor; Coto-Lesmes, Rocío</p>	<p>2023</p>	<p>Patients´ and Therapists´ Reports of Psychotherapy Outcomes: Similarities and Differences</p>	<p>Psicothema</p>	<p>35</p>	<p>4</p>	<p>374–384</p>	<p>BACKGROUND: Discrepancies between therapists' and patients' measures regarding therapeutic results indicate the need to analyze which symptoms and processes are being taken into consideration when reporting clinical change. This study analyzes the concordance between patient and therapist, at pre- and post-treatment, when reporting about anxiety, depression, Experiential Avoidance (EA), Cognitive Fusion (CF) and Activation (A). METHOD: Convergence was examined between information obtained by means of standardized measures and visual analogical scales (VAS) in 94 patients with anxiety and/or depression who participated in a controlled clinical study (TRANSACTIVA study). RESULTS: Statistically significant correlation ($p < .05$) was found between all the measures of anxiety and depression, regardless of the source, timepoint, and measures procedure at 95% confidence. In the VAS, patient and therapist agreed ($p < .05$) in their evaluation of specific symptoms. For EA, CF and A, the therapists' measures demonstrated stronger correlations than those of the patients, although, in each condition, all the patients'</p>

							measures correlated with each other ($p < .05$). CONCLUSIONS: Suitable agreement was found between therapist and patient when reporting clinical change. One-item VAS appeared to be suitable for identifying anxiety, depression and the transdiagnostic patterns of EA, CF and A.
Ferreira, Joana F.; Vasco, António B.; Basseches, Michael; Santos, Andreia; Ferreira, João M.	2016	Exploring Phase Progression Throughout the Therapeutic Process: The Case of Eva	Clinical psychology & psychotherapy	23	5	407-424	UNLABELLED This study intends to clarify how Eva [a good-outcome case] developed a more differentiated and integrated sense of herself and her experience, and how the therapist facilitated this developmental process. It aims to deepen our understanding of the processes of change throughout the therapeutic process by analysing a longitudinal case study integrating a phase-by-phase map-the sequential phases of the Paradigmatic Complementarity Metamodel [PCM]-with a moment-by-moment tracking method-the Developmental Analysis of Psychotherapy Process [DAPP] Method. A team of three researchers analysed the sessions from the first year of therapy, identified phase transitions and consolidations, and discussed what in the process appears to have fostered them. The results suggest that Eva evolved in accordance with the sequence of phases proposed by the PCM, which we illustrate and explain with therapeutic interactions representative of Eva's development within the evolving therapeutic process. This case study is one of a series intended to contribute to the optimization of clinical decision making by identifying markers of phase progression and assessing the usefulness of the therapeutic interventions offered. Copyright © 2015 John Wiley & Sons, Ltd. KEY PRACTITIONER MESSAGE Integrating moment-by-moment and phase-by-phase

							guiding maps facilitates the understanding of therapeutic processes. Therapists' attunement and responsiveness to patients' assimilation capacities supports therapeutic progress. Being aware of both phase-by-phase and moment-by-moment movements in psychotherapy helps lead to better clinical decisions.
Feuerstein, Heinz-Joachim	2022	Decision-making: Applying experiential concepts to facilitate the inner process and its reflection in situations where decisions are to be made					In the field of research on decision-making, there are approaches from many schools of psychology and other disciplines, especially economics and behavior economics. Here some aspects of theory and practice of human decision-making processes will be outlined that arise from the study and conceptualization of the subjective, personal experiencing of decision-making situations. The focus is especially on those aspects which are relevant for facilitating decision-making by a facilitating partner (process facilitator, counselor, coach, therapist). The purpose of this article to demonstrate the potential of the experiential approach which is not only relevant for clinical applications, but also for the improvement of decision-making. Within this article we demonstrate an example for the functioning of Focusing-oriented decision-making. The label of this method is EDM - Experiential Decision-Making. We expect EDM to develop as a substantial new approach in nonclinical use of Focusing.
Feuerstein, Heinz-Joachim	2023	EDM - Experimentelle Entscheidungsbegleitung zur Unterstützung innerer Prozesse in Entscheidungssi					Auf dem Gebiet der Entscheidungsforschung gibt es Ansätze aus vielen Schulen der Psychologie und anderen Disziplinen, insbesondere der Wirtschaftswissenschaften und der Verhaltensökonomie. Hier sollen einige Aspekte der Theorie und Praxis menschlicher Entscheidungsprozesse skizziert werden, die sich aus der Untersuchung und Konzeptualisierung des subjektiven, persönlichen Erlebens von Entscheidungssituationen

		<p>situationen - einige markante Punkte ihrer Weiterentwicklung</p>				<p>ergeben. Der Fokus liegt dabei insbesondere auf den Aspekten, die für die Begleitung von Entscheidungsprozessen durch einen Begleiter (Prozessbegleiter, Berater, Coach, Therapeut) relevant sind. Ziel dieses Artikels ist es, das Potenzial des erfahrungsbasierten Ansatzes aufzuzeigen, der nicht nur für klinische Anwendungen, sondern auch für die Verbesserung der Entscheidungsfindung im Alltag relevant ist. Es wird ein Beispiel für die Funktionsweise der focusing-orientierten Entscheidungsfindung gezeigt. Die Bezeichnung für diese Methode lautet EDM - Experiential Decision-Making. Wir erwarten, dass sich EDM als ein wesentlicher neuer Ansatz in der nicht-klinischen Anwendung von Focusing entwickeln wird, er kann auch im Jugendlichenalter Anwendung finden.</p>
Fiedler, Peter	2018	<p>Varianten psychotherapeutischer Beziehung. Transdiagnostische Befunde, Konzepte, Perspektiven</p>				<p>In der Psychotherapie ist die Beziehung zwischen Klient und Therapeut der wichtigste Erfolgsfaktor: Es geht weniger darum, Patienten zu ändern, als mit ihnen gemeinsam solidarisch widrige Lebensumstände zu bearbeiten. Wenn Therapie wirken soll, muss sie den Klienten extrem variabel annehmen. Die Beziehungskompetenzen in verschiedenen therapeutischen Richtungen unterscheiden sich teilweise deutlich und lassen sich in einem produktiven Ergänzungsverhältnis verstehen. Vor diesem Hintergrund werden gut evaluierte Varianten der Therapiebeziehungen vorgestellt. Die aktuelle Bestandsaufnahme möglicher Vielgestaltigkeit soll den Blick für die klinische Praxis erweitern. Psychotherapeuten und Psychotherapeutinnen erhalten Anregungen, nicht nur ihre Beziehungen, sondern auch ihr Selbstverständnis neu zu reflektieren und fortzuentwickeln. - Inhalt: (1) Thomas Schnell und Roland Weierstall: Therapeutische Beziehung in der</p>

Fierro, Catriel	2021	“A backdrop for psychotherapy”: Carl R. Rogers, psychological testing, and the psycho-educational clinic at Columbia University’s Teachers College (1924–1935)	History of Psychology	24	4	323–349	Carl Rogers’ work in clinical psychology and psychotherapy has been as influential as it is vast and varied. However, as a topic of historical inquiry Rogers’ approach to clinical psychology is beset by historiographical lacunae. Especially vague have been Rogers’ own reflections about his student years (1925–1928) at Columbia University’s Teachers College. Rogers claimed that he received the “backdrop” for the development of his approach to psychotherapy at the College. However, most historical literature has overlooked Rogers’ early years by focusing on his later work. This article aims to shed light on Rogers’ initial academic education by delving into his backdrop idea. I explore Rogers’ early years at Columbia by using his retroactive appraisals as a conduit for reconstructing his first formal institutional context—Columbia’s highly active but short-lived psycho-educational clinic. By drawing on several archival sources and unpublished materials, I will argue that the College’s intellectual and institutional climate fostered Rogers’ appreciation of experiential and cognitive learning while stimulating his intellectual independence as a clinical psychologist. The clinic put him in contact with real children, trained him in psychological tests, offered concrete professional role models, and pointed him toward his lifelong concern with human individuality. This contextual reading of Rogers’ education allows for a deeper, more informed understanding of both his academic origins and his immediate intellectual context amid American clinical psychology during the interwar years. <p>Finch, Ellen F.; Kleiman, Evan M.; Bentley, Kate H.; Bernstein, Emily E.</p>	<p>2023</p>	<p>Helpful for all? Examining the effects of psychotherapy treatment history on outcomes of single session, transdiagnostic cognitive behavioral interventions for university students</p>	<p>Psychological Services</p>			<p>No Paginat ion Specified -No Paginat ion Specified</p>	<p>Brief, transdiagnostic interventions are an efficient form of mental health care for resource-limited settings like universities. Little research, however, has examined for whom these treatments are most effective. One important factor may be psychotherapy treatment history. Here, we evaluate if treatment history influences the effects of a single-session cognitive behavioral group intervention with optional digital follow-up support across two independent, university-based studies. Undergraduate (N = 143) and graduate (N = 51) students reported their psychotherapy treatment history and completed self-report measures of emotional health before and approximately 1-month following the intervention. Across both samples, psychotherapy treatment history did not moderate changes in depression, anxiety, or emotional avoidance following the intervention. However, participants who were currently receiving psychotherapy began the workshop with lower coping self-efficacy than peers with no prior psychotherapy and saw larger gains in coping self-efficacy at follow-up. Results suggest that regardless of whether a student has previously received psychotherapy, they may benefit from brief, group transdiagnostic interventions. (Psychiatry and Clinical Neurosciences)</p>	<p>78</p>	<p>1</p>	<p>19–28</p>	<p>Aim Childhood sexual abuse (CSA) among women is an alarmingly prevalent traumatic experience that often leads to debilitating and treatment-refractory posttraumatic stress disorder (PTSD), raising the need for novel adjunctive therapies. Neuroimaging investigations systematically report that amygdala hyperactivity is the most consistent and reliable neural abnormality in PTSD and following childhood abuse, raising the potential of</p>

Hendler, Talma; Bloch, Miki		resistant childhood sexual abuse posttraumatic stress disorder: feasibility study				implementing volitional neural modulation using neurofeedback (NF) aimed at down-regulating amygdala activity. This study aimed to reliably probe limbic activity but overcome the limited applicability of functional magnetic resonance imaging (fMRI) NF by using a scalable electroencephalogram NF probe of amygdala-related activity, termed amygdala electrical-finger-print (amyg-EFP) in a randomized controlled trial. Method Fifty-five women with CSA-PTSD who were in ongoing intensive trauma-focused psychotherapy for a minimum of 1?year but still met Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) PTSD criteria were randomized to either 10 add-on sessions of amyg-EFP-NF training (test group) or continuing psychotherapy (control group). Participants were blindly assessed for PTSD symptoms before and after the NF training period, followed by self-reported clinical follow-up at 1, 3, and 6 months, as well as one session of amygdala real-time fMRI-NF before and after NF training period. Results Participants in the test group compared with the control group demonstrated a marginally significant immediate reduction in PTSD symptoms, which progressively improved during the follow-up period. In addition, successful neuromodulation during NF training was demonstrated. Conclusion This feasibility study for patients with treatment-resistant CSA-PTSD indicates that amyg-EFP-NF is a viable and efficient intervention.
Finger-Ossinger, Margarete	2018	Person(en)zentrierte Psychotherapie in Folge einer gerichtlichen Weisung - ein				Psychotherapie im Zwangskontext - allein diese Forderung scheint bereits das Scheitern vorwegzunehmen, wenn Psychotherapie per se an die Zustimmung des Patienten gebunden ist. Zahlreiche bungsprogramme wurden fr die Therapie mit Strafttern entwickelt, die der Personzentrierten Psychotherapie

		Versuch des Unmöglichen?					fremd sind und ihr widersprechen. Es wird darzustellen versucht, wie Personzentrierte Psychotherapie in der Arbeit mit Strafttern ihre Berechtigung haben kann und welche Aspekte dabei zu beachten sind. Drei Therapiephasen eines 32-jhnen Mannes, der eine gerichtliche Weisung an der Forensischen Ambulanz hatte, sollen neben theoretischer Reflexion die Herausforderungen an den Psychotherapeuten zur Diskussion stellen.
Fink, Birgit; Schultze-Gebhardt, Kathrin; Heyer, Martin; Projektgruppe "Online personzentriert Gruppen leiten und begleiten"	2022	Ob online oder in Prsenz: Ein Gruppenprozess muss erlebt werden. Finke, Jobst	2023	Das Netzwerk der Gefhle. Personzentrierte Emotionspsych ologie in Psychotherapie und Beratung					Die oft als berwltigend erlebten Gefhle der Angst, Trauer, Wut, Scham und Schuld sind hufig Anlass, therapeutische Hilfe zu suchen. Es wird ein neuer Weg erffnet, den empathischen Zugang zu Klientinnen und Klienten zu erweitern. Erscheinungsbild, Funktion und Vernetzung der fnf Grundregungen werden transparent gemacht und die Wechselwirkungen emotionaler Anteile bei hufigen psychischen Strungsbildern werden analysiert. So knnen auch unterschwellige Gefhle identifiziert und in ihrem Zusammenspiel mit Bedrfnissen, Fantasien und Erinnerungen erfasst werden. Zahlreiche Formulierungsbeispiele zeigen, wie man Klientinnen und

							Klienten darin unterstützt, emotionale Spannungen bewusst wahrzunehmen, zu regulieren und für eigene Bedürfnisse und Selbstentfaltung fruchtbar zu machen. - Inhalt: https://d-nb.info/1288184220/04
Finke, Jobst	2020	Personenzentriertes Arbeiten an der therapeutischen Beziehung	Gesprächspsychotherapie und Personenzentrierte Beratung	51	1	6-10	Thematisiert wird die therapeutische Beziehungsarbeit im Rahmen der personenzentrierten Psychotherapie. Dabei steht das Beziehungsklima im Vordergrund, das durch Beziehungsansprachen und Beziehungsanspielungen unterstützt wird. Hierbei kann der/die Therapeut/in etwa allgemein gehaltene Aussagen des Patienten/der Patientin auf sich beziehen und entsprechend reagieren und die Selbstexploration und das Selbstverstehen fördern. Im Sinne der Echtheit und Kongruenz spielt auch die angemessen angewandte Selbstöffnung und - einbringung eine bedeutsame Rolle. Insbesondere bei der Selbstöffnung sind jedoch auch Risiken zu berücksichtigen, etwa die Wahl eines unangemessenen Zeitpunkts oder mögliche unbeabsichtigte Auswirkungen.
Finke, Jobst	2022	Bindungs- und Abhängigkeitsphänomene in der personenzentrierten Beziehung	Gesprächspsychotherapie und Personenzentrierte Beratung	53	1	8-13	Es wird der Frage nachgegangen, welche Rolle die Bindungstheorie für die Personenzentrierte Psychotherapie (PZT) spielen kann und welche Bedeutung "Bindung" und personale Abhängigkeit in der therapeutischen Beziehung der PZT haben. In Anlehnung an Fachliteratur wird die Vermutung geäußert, dass Rogers sehr "abhängigkeitssensibel" war und sich schwertat mit Klienten innen, die eine enge, aber "verstrickte" Bindung zu ihm suchten. Auch hat die PZT den therapeutischen Umgang mit abhängigen und "verstrickt gebundenen" Klienten kaum thematisiert. Konzepte für einen solchen Umgang werden gefordert und ansatzweise auch vorgestellt.

Finke, Jobst	2017	Gesprächspsychotherapie der Depression				<p>Nach einer kurzen Beschreibung der Strungs- und Therapietheorie sowie des Konzepts der Depressionsentstehung wird die Anwendungspraxis anhand von 6 Therapiebausteinen dargestellt. Der erste Therapiebaustein betrifft die Einleitung einer Therapie und die Erörterung ihrer Voraussetzungen, mit dem 6. Baustein werden Implikationen und Regularien des Therapieendes beschrieben. Mit den übrigen 4 Bausteinen kommen die Handlungskonzepte des Verfahrens zur Darstellung. Der zentrale Baustein kreist um das Thema Einfühlen und Verstehen mit dem Ziel einer Selbsterkundung und einer Selbstreflexion des Patienten in der Sicherheit der therapeutischen Beziehung. Die anderen Bausteine sollen die Realisierung dieses Ziels auf unterschiedliche Weise unterstützen und ergänzen. Auf dem Hintergrund eines Fallbeispiels wird die Anwendung dieser Konzepte in Form von Therapeut-Patient-Interaktionen erörtert. Schließlich wird beschrieben, wie das widersprüchliche Interaktionsverhalten mancher Depressiver zu einem Fallstrick für den Therapeuten werden kann. (c) Springer-Verlag GmbH Deutschland</p>
Finke, Jobst	2018	Depressive Strungen				<p>In diesem Kapitel geht es um die für den Indikationsbereich der Personzentrierten Psychotherapie wichtigsten depressiven Strungen. Bei der Therapie von schwer Depressiven ist ein so stark modifiziertes Vorgehen angezeigt, dass man von einer besonderen Art personenzentrierter Pr-Therapie sprechen könnte. Bei den anderen hier besprochenen Strungsgruppen ist zwar die "klassische" personenzentrierte Zugangsart angemessen, jedoch sind auch hier einige Besonderheiten zu beachten, wie etwa die starke Bedürftigkeit vieler dieser Klienten nach Zuwendung und Anerkennung, eine leichte Kränkbarkeit und die Neigung zu einem symbiotischen</p>

							Beziehungserleben, was sich besonders bei den Klienten mit einer abhängigen Persönlichkeitsstruktur zeigt. Dies muss der Therapeut sowohl hinsichtlich der Art seiner Verstehensangebote als auch in Bezug auf seine Beziehungsgestaltung und seine Bereitschaft zur Beziehungsklärung berücksichtigen. (c) Springer-Verlag GmbH Deutschland
Finke, Jobst; Straumann, Ursula; Winter, Elena	2022	Ehrenhaftes Engagement für den Personzentrierten Ansatz. Beim Jahreskongress ehrte die GwG mit Prof. Ursula Straumann und Dr. Jobst Finke zwei langjährige Mitglieder für ihre Verdienste rund um die Weiterentwicklung des Personzentrierten Ansatzes	Gesprächspsychotherapie und Personzentrierte Beratung	53	3	18–19	Beim Jahreskongress ehrte die GwG mit Prof. Ursula Straumann und Dr. Jobst Finke zwei langjährige Mitglieder für ihre Verdienste rund um die Weiterentwicklung des Personzentrierten Ansatzes. Im Interview berichten die beiden über ihre Zeit in und mit der GwG.
Finsrud, Ingvild; Nissen-Lie, Helene A.; Ulvenes, Pål G.; Vrabel, KariAnne; Melsom, Linne;	2023	Emotional and cognitive processes in psychotherapy are associated with different aspects of the	Journal of consulting and clinical psychology			No Page Number Specified -No Page Number Specified	Objective: In this naturalistic study we aimed to investigate the relationships between two central change processes (affective and cognitive) and two common relationship factors (“Confidence in the therapist” and “Confidence in the treatment”), which have been shown to impact outcomes in a clinical context. We also investigated whether these interrelationships varied across treatment orientations (i.e., cognitive or

Wampold, Bruce		therapeutic relationship				<p>psychodynamic focused). Method: The sample consisted of 631 patients with a primary anxiety or depressive disorder who were admitted to an inpatient program and treated with psychotherapy. The data consisted of weekly measures of cognitive (i.e., “rumination”) and affective (i.e., “problems with emotional clarity”) change processes as well as scores on Confidence in the therapist and Confidence in the treatment and symptom distress. A multivariate version of the latent curve model with structured residuals was used to investigate the within-patient effects of week-to-week changes in all variables. Results: Initial analyses established that both problems with emotional clarity and rumination predicted symptom distress. Further, we found that higher Confidence in the therapist predicted higher emotional clarity (but not lower rumination) whereas higher Confidence in the treatment predicted lower rumination (but did not affect emotional clarity). Post hoc analyses found that these interrelationships varied across treatment orientation (i.e., cognitive vs. psychodynamic). Discussion: The results indicate that patients’ experience of the therapist is associated with emotional change processes, and that patients’ experience of the coherence and meaningfulness of treatment, on the other hand, is associated with cognitive change processes. Implications for clinical practice are discussed. (PsychoInfo Database Record (c) 2023 APA, all rights reserved)</p>
Finsrud, Ingvild; Nissen-Lie, Helene A.; Ulvenes, Pål; Melsom, Linne; Vrabel,	2022	Confidence in the therapist and confidence in the treatment predict symptomatic		69	6	<p>Previous research suggests that common relationship factors are composed of two overarching factors, “Confidence in the therapist” and “Confidence in the treatment.” The aim of this naturalistic process–outcome study was to investigate the reciprocal relationships between these two constructs and patients’ symptom</p>

KariAnne; Wampold, Bruce		improvement week by week in therapy: A latent curve modeling approach					level across treatment. The sample consisted of 587 patients who were admitted to an inpatient program and treated with psychotherapy for a range of mental health disorders, such as chronic depression, anxiety disorders, and eating disorders. Our data consisted of weekly measures of symptomatic distress (Patient Health Questionnaire) and the common relationship factors were measured weekly using a newly developed scale. Latent curve modeling with structured residuals was used to investigate the between- and within effects of week-to-week changes in the two components as predictors of subsequent symptom level. An increase in both relationship factors predicted a decrease in subsequent levels of symptoms at the within-patient level, and the other way around, but the two relationship factors did not systematically relate to one another at the within-patient level over the course of treatment. Our findings indicate that patients' perceptions of the therapist as a person and their appraisal of the treatment, are important, different predictors of therapeutic change. Furthermore, they support prior research demonstrating a reciprocal relationship between common relationship factors and symptomatic distress and add to existing common factor theory by exploring the role of two central relationship dimensions and using a method which examines reciprocal relationships and within-patient effects simultaneously. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Firth, Nick; Saxon, David; Stiles, William B.; Barkham, Michael	2019	Therapist and clinic effects in psychotherapy: A three-level model of	Journal of consulting and clinical psychology	87	4	345–356	Objective: The study aimed to (a) investigate the effect of treatment location on clinical outcomes for patients receiving psychological therapy (a clinic effect, akin to the concept of a therapist effect) and (b) assess the impact of explanatory individual and aggregate demographic and

		outcome variability					<p>process variables on the clinic and therapist effects. Method: The sample comprised 26,888 patients, seen by 462 therapists, across 30 clinics. Mean patient age was 38 years (69% female, 90% White, 92% planned ending). The dependent variable was patients' posttherapy score on the Clinical Outcomes in Routine Evaluation—Outcome Measure. An incremental 3-level multilevel model was constructed. Markov Chain Monte Carlo estimation created 95% probability intervals for the clinic and therapist effects. Results: A 3-level model with no explanatory variables detected a clinic effect of 8.2%, significantly larger than the therapist effect of 3.2%. Adding explanatory variables significantly reduced the clinic effect to 1.9% but did not significantly alter the therapist effect (3.4%). Patient-level symptom severity and employment status, and clinic-level percentage of White patients and health care sector, explained the most clinic outcome variance and overall outcome variance. Conclusions: Substantial variability in clinical outcomes was found between clinics providing psychological therapy. Socioeconomic mix of patients explained significant proportions of variability at the clinic level but not the therapist level. Clinical implications include the need to go beyond the therapist–patient interaction to deliver effective psychological therapy. Future research is also needed to identify the mechanisms by which clinic and/or area-level factors impact on clinical outcomes. (PsycINFO Database Record (c) 2019 APA, all rights reserved)</p>
Fischer-Kern, M.; Leithner, K.; Hilger, E.;	2004	Context-Oriented Model Development in Psychotherapy	Acta psychiatrica Scandinavica	109	3	235–238	<p>OBJECTIVE Pathogenous interpersonal (e.g. interfamilial) relationships and reference styles can compromise treatment efforts in severely disturbed (i.e. psychotic or</p>

Löffler-Stastka, H.; Schuster, P.		Planning ('COMEPP'): a useful adjunct to diagnosis and therapy of severe personality disorders					borderline) patients. The integration of family- and individual-centred starting points may be useful in establishing interdisciplinary treatment concepts in these patients. Context-Oriented Model Development in Psychotherapy Planning (COMEPP) represents a diagnostic and therapy planning process, integrating both systemic and psychoanalytic conceptualizations. METHOD COMEPP is exemplified by the case of a young man with psychotic personality disorder who had previously been unresponsive to pharmacological and psychological treatment. RESULTS After psycho-dynamical conflicts (i.e. primitive projective processes from the patient's mother to her son) had been elucidated during the COMEPP process, a sufficient treatment setting could be established. CONCLUSION COMEPP provides a psychotherapeutical approach to treatment planning on case-specific premises and may serve as an adjunct to concomitant pharmacological and psychological treatment strategies in so-called 'therapy refractory' patients.
Fishbein, Joel N.; Haslbeck, Jonas; Arch, Joanna J.	2023	Network intervention analysis of anxiety-related outcomes and processes of acceptance and commitment therapy (ACT)	Behaviour research and therapy	162		104266	OBJECTIVE: Psychotherapies like Acceptance and Commitment Therapy (ACT) are thought to target multiple clinical outcomes by intervening on multiple mechanistic process variables. However, the standard mediation approach does not readily model the potentially complex associations among multiple processes and outcomes. The current study is one of the first to apply network intervention analysis to examine the putative change processes of a psychotherapy. METHODS: Using data from a randomized trial of ACT versus minimally-

		for anxious cancer survivors					enhanced usual care for anxious cancer survivors, we computed pre-to post-intervention (n = 113) residualized change scores on anxiety-related outcomes (general anxiety symptoms, cancer-related trauma symptoms, and fear of cancer recurrence) and putative processes of the intervention (experiential avoidance, self-compassion, and emotional approach coping). We estimated a network model with intervention condition and residualized change scores as nodes. RESULTS: Contrary to the expectation that intervention effects would pass indirectly to outcomes via processes, network analysis indicated that two anxiety-related outcomes of the trial may have acted as primary mechanisms of the intervention on other outcome and process variables. CONCLUSIONS: Network intervention analysis facilitated flexible evaluation of ACT's change processes, and offers a new way to test whether change occurs as theorized in psychotherapies.
Fishbein, Joel N.; Judd, Charles M.; Genung, Sarah; Stanton, Annette L.; Arch, Joanna J.	2022	Intervention and mediation effects of target processes in a randomized controlled trial of Acceptance and Commitment Therapy for anxious cancer survivors in community oncology clinics	Behaviour research and therapy	153		104103	OBJECTIVE: Acceptance and Commitment Therapy (ACT) is a promising psycho-oncological intervention, but its mechanisms in real-world settings are not fully understood. This study examined core theorized ACT and broader ACT-consistent target processes as mediators of ACT versus minimally-enhanced usual care within a randomized trial for anxious cancer survivors in a community oncology setting. METHOD: Two core theorized ACT target processes (experiential avoidance and values-aligned behavior, each measured with two instruments) and two broader ACT-consistent target processes (emotional approach coping and self-compassion) were analyzed at pre- and post-intervention as mediators of general anxiety symptoms, cancer-related trauma symptoms, and fear of cancer recurrence

							(N = 134). RESULTS: ACT led to greater increases on emotional approach coping (ps ≤ .001) and one measure of values-aligned behavior (ps ≤ .031), and marginal or greater improvement on self-compassion (ps ≤ .055), but not other core ACT target processes. Self-compassion and emotional approach coping mediated ACT's effects on cancer-related trauma symptoms (ps ≤ .037). Additionally, self-compassion, emotional approach coping, and values-aligned behavior marginally mediated fear of recurrence and general anxiety symptoms improvement (ps ≤ .088). CONCLUSION: ACT reduced cancer survivors' anxiety-related symptoms, and especially cancer-related trauma symptoms, most consistently by promoting self-compassion and emotional approach coping.
Fisher, Caroline A.; Skocic, Sonja; Rutherford, Kathleen A.; Hetrick, Sarah E.	2019	Family therapy approaches for anorexia nervosa	The Cochrane database of systematic reviews	5	5	CD004780	<p>BACKGROUND</p> <p>Anorexia nervosa (AN) is characterised by a failure to maintain a normal body weight due to a paucity of nutrition, an intense fear of gaining weight or behaviour that prevents the individual from gaining weight, or both. The long-term prognosis is often poor, with severe developmental, medical and psychosocial complications, high rates of relapse and mortality. 'Family therapy approaches' indicate a range of approaches, derived from different theories, that involve the family in treatment. We have included therapies developed on the basis of dominant family systems theories, approaches that are based on or broadly similar to the family-based therapy derived from the Maudsley model, approaches that incorporate a focus on cognitive restructuring, as well as approaches that involve the family without articulation of a theoretical approach. This is an update of a Cochrane Review first published in 2010.</p>

						<p>OBJECTIVES To evaluate the efficacy of family therapy approaches compared with standard treatment and other treatments for AN.</p> <p>SEARCH METHODS We searched the Cochrane Common Mental Disorders Controlled Trials Register (CCMDCTR) and PsycINFO (OVID) (all years to April 2016). We ran additional searches directly on Cochrane Central Register for Controlled Trials (CENTRAL), MEDLINE, Ovid Embase, and PsycINFO (to 2008 and 2016 to 2018). We searched the World Health Organization (WHO) trials portal (ICTRP) and ClinicalTrials.gov, together with four theses databases (all years to 2018). We checked the reference lists of all included studies and relevant systematic reviews. We have included in the analyses only studies from searches conducted to April 2016.</p> <p>SELECTION CRITERIA Randomised controlled trials (RCTs) of family therapy approaches compared to any other intervention or other types of family therapy approaches were eligible for inclusion. We included participants of any age or gender with a primary clinical diagnosis of anorexia nervosa.</p> <p>DATA COLLECTION AND ANALYSIS Four review authors selected the studies, assessed quality and extracted data. We used a random-effects meta-analysis. We used the risk ratio (with a 95% confidence interval) to summarise dichotomous outcomes and both the standardised mean difference and the mean difference to summarise continuous measures.</p> <p>MAIN RESULTS We included 25 trials in this version of the review (13 from</p>
--	--	--	--	--	--	--

						<p>the original 2010 review and 12 newly-included studies). Sixteen trials were of adolescents, eight trials of adults (seven of these in young adults aged up to 26 years) and one trial included three age groups: one adolescent, one young adult and one adult. Most investigated family-based therapy or variants. Reporting of trial conduct was generally inadequate, so that in a large number of studies we rated the risk of bias as unclear for many of the domains. Selective reporting bias was particularly problematic, with 68% of studies rated at high risk of bias in this area, followed by incomplete outcome data, with 44% of studies rated at high risk of bias in this area. For the main outcome measure of remission there was some low-quality evidence (from only two studies, 81 participants) suggesting that family therapy approaches might offer some advantage over treatment as usual on rates of remission, post intervention (risk ratio (RR) 3.50, 95% confidence interval (CI) 1.49 to 8.23; I² = 0%). However, at follow-up, low-quality evidence from only one study suggested this effect was not maintained. There was very low-quality evidence from only one trial, which means it is difficult to determine whether family therapy approaches offer any advantage over educational interventions for remission (RR 9.00, 95% CI 0.53 to 153.79; 1 study, N = 30). Similarly, there was very low-quality evidence from only five trials for remission post-intervention, again meaning that it is difficult to determine whether there is any advantage of family therapy approaches over psychological interventions (RR 1.22, 95% CI 0.89 to 1.67; participants = 252; studies = 5; I² = 37%) and at long-term follow-up (RR 1.08, 95% CI 0.91 to 1.28; participants = 200; studies = 4 with 1 of these contributing 3 pairwise comparisons for different age</p>
--	--	--	--	--	--	---

						<p>groups; I2 = 0%). There was no indication that the age group had any impact on the overall treatment effect; however, it should be noted that there were very few trials undertaken in adults, with the age range of adult studies included in this analysis from 20 to 27. There was some evidence of a small effect favouring family based therapy compared with other psychological interventions in terms of weight gain post-intervention (standardised mean difference (SMD) 0.32, 95% CI 0.01 to 0.63; participants = 210; studies = 4 with 1 of these contributing 3 pairwise comparisons for different age groups; I2 = 11%) . Overall, there was insufficient evidence to determine whether there were any differences between groups across all comparisons for most of the secondary outcomes (weight, eating disorder psychopathology, dropouts, relapse, or family functioning measures), either at post-intervention or at follow-up.</p> <p>AUTHORS' CONCLUSIONS</p> <p>There is a limited amount of low-quality evidence to suggest that family therapy approaches may be effective compared to treatment as usual in the short term. This finding is based on two trials that included only a small number of participants, and both had issues about potential bias. There is insufficient evidence to determine whether there is an advantage of family therapy approaches in people of any age compared to educational interventions (one study, very low quality) or other psychological therapies (five studies, very low quality). Most studies contributing to this finding were undertaken in adolescents and youth. There are clear potential impacts on how family therapy approaches might be delivered to different age groups and further work is required to understand what the resulting effects</p>
--	--	--	--	--	--	--

							on treatment efficacy might be. There is insufficient evidence to determine whether one type of family therapy approach is more effective than another. The field would benefit from further large, well-conducted trials.
Fisher, Hadar; HaCohen, Nehama; Shimshi, Sharon; Rand-Lakritz, Shira; Shapira, Kineret; Tuval-Mashiach, Rivka	2020	Ability to move between self-states and emotional experiencing and processing as predictors of symptomatic change	Psychology and psychotherapy	93	4	723–738	<p>Objectives Contemporary relational theories consider clients? ability to move between multiple self-states and clients? ability to experience and process emotions to be two therapeutic processes inherently connected and fundamental to growth and change in psychotherapy. The current research aimed to empirically explore these theoretical assumptions by (1) examining the between- and within-client temporal association between clients? levels of ability to move between multiple self-states and clients? emotional experiencing and processing over the course of therapy, and by (2) testing whether this association would be more prominent for clients presenting good treatment outcomes. Method Based on treatment outcome measures, two contrasting groups were selected, nine successful and nine unsuccessful. Ninety session transcripts (five per client) were analysed using the Two-Person APES (TPA), an extension of the Assimilation of Problematic Experiences Scale (APES), for the measurement of the ability to move between self-states. Sessions were also analysed using the Experiencing Scale (EXP), for the measurement of emotional experiencing. For all predictors, we disaggregated within- and between-client effects. Results No association was found between EXP and TPA levels. However, at the between-client level, an interaction effect was found indicating a positive correlation between TPA and EXP only for the good-outcome cases, whereas a negative correlation between these variables was found for the poor-outcome cases. Conclusions The ability to</p>

							<p>move between multiple self-states and accessibility to emotional experiencing may be seen as complementary processes enhancing the effectiveness of therapy. However, a high level of one process combined with a low level of the other may be a sign of poor therapeutic outcome. Practitioner points Clients? capacity to negotiate between conflicted self-states and their ability to experience and process emotions are two determinants working in a synergistic way to predict improvement in clients? symptoms. The presence of only one of these psychological processes without the other might be an indication of poor therapeutic outcome. Therapists should aim to increase their clients? progress in both the movement between self-states and emotional experiencing.</p>
<p>Fisher, Lawrence; Hessler, Danielle; Polonsky, William H.; Masharani, Umesh; Guzman, Susan; Bowyer, Vicky; Strycker, Lisa; Ahmann, Andrew; Basina, Marina; Blumer, Ian; Chloe, Charles; Kim, Sarah; Peters, Anne L.;</p>	2018	T1-REDEEM: A Randomized Controlled Trial to Reduce Diabetes Distress Among Adults With Type 1 Diabetes	Diabetes care	41	9	1862–1869	<p>OBJECTIVE To compare the effectiveness of two interventions to reduce diabetes distress (DD) and improve glycemic control among adults with type 1 diabetes (T1D).</p> <p>RESEARCH DESIGN AND METHODS Individuals with T1D (n = 301) with elevated DD and HbA1c were recruited from multiple settings and randomly assigned to OnTrack, an emotion-focused intervention, or to KnowIt, an educational/behavioral intervention. Each group attended a full-day workshop plus four online meetings over 3 months. Assessments occurred at baseline and 3 and 9 months. Primary and secondary outcomes were change in DD and change in HbA1c, respectively.</p> <p>RESULTS With 12% attrition, both groups demonstrated dramatic reductions in DD (effect size d = 1.06; 78.4% demonstrated a reduction of at least one minimal</p>

Shumway, Martha; Weih, Karen; Wu, Patricia							<p>clinically important difference). There were, however, no significant differences in DD reduction between OnTrack and Knowlt. Moderator analyses indicated that OnTrack provided greater DD reduction to those with initially poorer cognitive or emotion regulation skills, higher baseline DD, or greater initial diabetes knowledge than those in Knowlt. Significant but modest reductions in HbA1c occurred with no between-group differences. Change in DD was modestly associated with change in HbA1c ($r = 0.14$, $P = 0.01$), with no significant between-group differences.</p> <p>CONCLUSIONS</p> <p>DD can be successfully reduced among distressed individuals with T1D with elevated HbA1c using both education/behavioral and emotion-focused approaches. Reductions in DD are only modestly associated with reductions in HbA1c. These findings point to the importance of tailoring interventions to address affective, knowledge, and cognitive skills when intervening to reduce DD and improve glycemic control.</p>
Flahault, Cécile; Vioulac, Christel; Fasse, Léonor; Bailly, Sébastien; Timsit, Jean-François; Garrouste-Orgeas, Maité	2022	"A story with gaps": An interpretative phenomenological analysis of ICU survivors' experience	PloS one	17	3	e0264310	<p>ICU survivors may experience various long-term sequelae, recognized as Post-Intensive Care Syndrome, that includes psychiatric symptoms: anxiety, depression, and post-traumatic stress disorders symptoms (PTSD). While it was hypothesized that an ICU diary could help patients after discharge, improving their hospitalization memories and quality of life, it is unclear whether it may reduce psychiatric disorders, in particular PTSD. We performed a qualitative exploration of survivors' subjective experience of their ICU stay, their representations, memories, meaning-making of their experience and use of their ICU diary. Five participants (ICU survivors, 3 men and 2 women, who received a diary)</p>

						<p>were included in this study. We conducted non-directive interviews 6 months after discharge. These interviews were transcribed and analyzed using Interpretative Phenomenological Analysis. Major recurring themes of discourse included: (1) The nightmare of the ICU experience: from an impression of vagueness to dispossession, (2) The positive image of health-care workers during intensive care, (3) The place of the relatives and health-care workers' writings in the diary: either a support or a barrier, (4) The difficult return back home, and daily life after intensive care. Participant's representation of their ICU experience seemed to reflect the meaning they had given it through their own reflections and that of health-care workers in the diary. For some participant, the diary was associated to the pain and strangeness of the ICU experience; therefore, their recovery required them to take some distance with it. The ICU diary allowed participants to construct their illness narratives, and to become aware of the presence and support of health-care workers. The diary was also perceived as the witness of a period they wished to forget. Trial registration: NCT02519725.</p>
<p>Flechtenhar, Aleya; Seitz, Katja I.; Bertsch, Katja; Herpertz, Sabine C.</p>		<p>The association between psychopathology, childhood trauma, and emotion processing</p>	<p>Psychological Trauma: Theory, Research, Practice, and Policy</p>			<p>Objective: Childhood trauma is highly prevalent and can have a negative impact on the development of socioemotional processes resulting in a higher vulnerability for mental disorders in adulthood. Previous studies have associated the severity of childhood trauma with deficits in social functioning, such as a negative attention bias, suggesting altered social information processing as a mechanism underlying the association between childhood trauma and transdiagnostic psychopathologies. Method: In a cross-sectional setup with a total of 103 participants (26 with major depressive</p>

							<p>disorder, MDD; 24 with posttraumatic stress disorder, PTSD; 22 with somatic symptom disorder, SDD; and 31 healthy volunteers, HV), this study applied eye tracking in an emotion recognition paradigm. Reaction times, accuracy, and gaze behavior were analyzed for 4 different facial expressions as a function of self-reported childhood trauma and diagnosis. The aim was to investigate to what extent emotion processing is associated with (a) childhood trauma, (b) psychopathology, and (c) respective interacting effects. Results: Patients showed higher reaction times and error rates overall in classifying emotions than HVs, especially for the recognition of anger and fear. Individuals with a diagnosis of PTSD and MDD were particularly slow in their response to these emotions. Higher scores of reported childhood trauma were associated with faster responses for classifying anger and fear and slower initiation of eye movements for SSD, MDD, and HVs for anger. Conclusion: These findings indicate that childhood trauma may contribute to attentional and information-processing biases relevant for social interaction. Identifying individual social deficits offers implications for tailored therapeutic interventions. (PsyInfo Database Record (c) 2022 APA, all rights reserved)</p>
Flender, Jrgen	2019	Prsente Gegenwrtigkeit als Potenzial begabungsrderl icher Begegnungen	Gesprchspsych otherapie und Personzentrierte Beratung	50	1	24–30	<p>Vor dem Hintergrund verschiedener klassischer und neuerer psychologischer und psychotherapeutischer Theorien wird fr einen strkeren Fokus auf die Erfahrung von Gegenwrtigkeit und Beziehung im Rahmen der Begabungsrderung pldiert. Nach der Beschreibung allgemeiner hilfreicher Merkmale fr Beziehungen werden drei Potenzialebenen vorgestellt, auf denen Beziehung und Begegnung begabungsrderlich wirken kann: Die Ebene der Selbstbegegnung, der Begegnung mit anderen</p>

							Menschen sowie der (existenziell wirksamen) Begegnung mit einem Letzten, Unbedingten. Geschlossen werden die Ausfhrungen mit einem Beispiel aus der Praxis der Begabungsforderung an der Internatsschule Schloss Hansenberg.
Florence, Ana Carolina; Jordan, Gerald; Yasui, Silvio; Cabrini, Daniela Ravelli; Davidson, Larry	2021	"It Makes us Realize that We Have Been Heard": Experiences with Open Dialogue in Vermont	The Psychiatric quarterly	92	4	1771–1783	The Open Dialogue approach was developed in Finland as a form of psychotherapy and a way to organize mental health systems. Open Dialogue has drawn global interest leading to adaptations worldwide, including in Vermont-US where it is called Collaborative Network Approach. Our study aimed to investigate the experiences of families who received Collaborative Network Approach in two agencies in Vermont. Qualitative interviews were conducted with 17 persons receiving services. Seven themes emerged: 1) network focus, 2) decision-making, 3) structure of care, 4) use of reflections, 5) medications, 6) hospitalizations, 7) challenges. Our study provides evidence that CNA is well-received, appreciated, and for many people an empowering form of mental health care. The findings suggest that elements of Open Dialogue are highly consistent with the vision for recovery-oriented care, in that they are flexible, person-centered, encourage processes of negotiation, and highlight the importance of family and social supports in care.
Flückiger, Christoph; Caspar, Franz; Holtforth, Martin Grosse; Willutzki, Ulrike	2009	Working with patients' strengths: a microprocess approach	Psychotherapy research : journal of the Society for Psychotherapy Research	19	2	213–223	Previous research has supported the immediate activation of patients' strengths (resource activation) as an important change mechanism in psychotherapy. Two different studies of integrative cognitive-behavioral therapy (CBT) treatments demonstrated that fostered strengths-oriented CBT treatments were more effective than the control conditions. Within these two studies, the authors tested the effect of specific resource-activating strategies at the beginning of therapy (Sessions 2, 5, and

							8) using a pairwise matched control group design. The in-session processes were measured by video observer ratings (N=96 sessions). Results indicate that in the strengths-fostering treatments therapists and patients focus more strongly on patient competencies and personal goals in comparison to the control groups. These in-session processes have a direct impact on session outcome (particularly self-esteem, mastery, and clarification experiences). Results are discussed in regard to actively implementing resource-activating behavior as superordinate principles of change and their relevance for therapy outcome.
Flückiger, Christoph; Hilpert, Peter; Goldberg, Simon B.; Caspar, Franz; Wolfer, Christine; Held, Judith; VÍslá, Andreea	2019	Investigating the impact of early alliance on predicting subjective change at posttreatment: An evidence-based souvenir of overlooked clinical perspectives	Journal of Counseling Psychology	66	5	613–625	[Correction Notice: An Erratum for this article was reported in Vol 66(5) of Journal of Counseling Psychology (see record 2019-58882-002). In the article, a portion, $+Y_{40}ERit$, was omitted in the Model 3 formula. The corrected formula is presented in the erratum. All versions of this article have been corrected.] Despite meta-analytic evidence showing that alliance is associated with posttreatment outcomes, several open questions still remain regarding this relation. First, we investigate whether (or not) the progressive aggregation of early alliance assessments increases the alliance–outcome relation across 2 distress and 4 subjective change measures. Second, we investigate whether the alliance–outcome relations using subjective change measures are independent from intake distress and early response. Third, we explore whether the progressive aggregation of the alliance on outcomes becomes particularly apparent between or within therapists again investigating these six outcome measures. Data were drawn from N = 430 patients treated by N = 151 therapists. Patient ratings of early alliance were assessed

							<p>after Session 1 to 6. For outcome, 2 commonly used distress measures at intake and at posttreatment and 4 measures of retrospectively evaluated subjective change at posttreatment are integrated into a series of multilevel models. The proportion of variance in outcome predicted by alliance scores varied considerably depending on the number of alliance assessments which were aggregated, as well as on the type of outcome assessment (distress vs. subjective change measures) explaining up to 15% of outcome variance. Improvements in the strength of prediction with aggregated alliance assessments were most pronounced for subjective change measures for between-therapist components of the alliance. Examining associations with subjective change measures provides an additional, patient-centered perspective of the relation between early alliance and treatment outcomes. Flynn, Maureen K.; Berkout, Olga V.; Bordieri, Michael J.	2016	Cultural considerations in the measurement of psychological flexibility: Initial validation of the Acceptance and Action Questionnaire-II among Hispanic individuals	Behavior Analysis: Research and Practice	16	2	81-93	<p>The aim of this study was to examine the psychometric properties of the Acceptance and Action Questionnaire-II (AAQ-II) among Hispanic college students (N = 104). Consistent with previous studies, the AAQ-II enjoyed excellent internal consistency in this sample and fit a 1-factor solution. However, different method effects than those used in previous investigations had to be used to obtain a proper fit. High psychological inflexibility was associated with higher symptoms of depression, anxiety, and stress and lower levels of life satisfaction and mindfulness. The AAQ-II added to prediction of life satisfaction and psychological distress above and beyond measures of mindfulness and thought suppression. This study provides initial evidence that the AAQ-II may be a valid and reliable measure in Hispanic college student</p>

							populations. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Fonagy, Peter; Sleed, Michelle; Baradon, Tessa	2016	RANDOMIZED CONTROLLED TRIAL OF PARENT-INFANT PSYCHOTHERA PY FOR PARENTS WITH MENTAL HEALTH PROBLEMS AND YOUNG INFANTS	Infant mental health journal	37	2	97-114	ABSTRACT There is a dearth of good-quality research investigating the outcomes of psychoanalytic parent-infant psychotherapy (PIP). This randomized controlled trial investigated the outcomes of PIP for parents with mental health problems who also were experiencing high levels of social adversity and their young infants (<12 months). Dyads were clinically referred and randomly allocated to PIP or a control condition of standard secondary and specialist primary care treatment (n = 38 in each group). Outcomes were assessed at baseline and at 6-month and 12-month follow-ups. The primary outcome was infant development. Secondary outcomes included parent-infant interaction, maternal psychopathology, maternal representations, maternal reflective functioning, and infant attachment. There were no differential effects over time between the groups on measures of infant development, parent-infant interaction, or maternal reflective functioning. Infant attachment classifications, measured only at the 12-month follow-up, did not differ between the groups. There were favorable outcomes over time for the PIP-treated dyads relative to the control group on several measures of maternal mental health, parenting stress, and parental representations of the baby and their relationship. The findings indicate potential benefits of parent-infant psychotherapy for improving mothers' psychological well-being and their representations of their baby and the parent-infant relationship.
Fondren, Alana Harrison;		Horseshoe crabs and	Rorschachiana	41	2		Collaborative/Therapeutic Assessment (CTA; Finn, 2007) offers a person-centered approach to understanding

Jenkins, Sharon Rae		stingrays: A case study of interpersonal theory and multimethod collaborative/therapeutic assessment					clients' problems through mutual engagement with the client's experience of the data-gathering process. Key tenets of CTA include empowering the client to shape their own assessment questions and goals and connecting with the client in an empathic and meaningful manner. These tenets map onto the core domains of interpersonal theory – that is, agency and communion (Wiggins, 1996). Interpersonal theory can be utilized to conceptualize several different concerns that may arise through the client's questions during CTA, such as their interpersonal traits, problems, sensitivities, and so on. The present article provides a case conceptualization that utilizes contemporary integrative interpersonal theory (CIIT; Pincus, 2005) to conceptualize an assessment client who presented with symptoms of depression, anxiety, and gastrointestinal problems. Through a multimethod assessment approach grounded in the CTA and CIIT frameworks, the assessor gained a deeper understanding of how the client's presenting problems are tied to her interpersonal patterns. Finally, the present article explores how interpersonal processes that unfolded during the assessment sessions informed case conceptualization and treatment planning. The synthesis of CTA and CIIT offers promising avenues for new methods of understanding clients' questions through the lens of interpersonal relationships. Fonzo, Gregory A.; Goodkind, Madeleine S.; Oathes, Desmond J.; Zaiko, Yevgeniya	2017	Selective Effects of Psychotherapy on Frontopolar Cortical	The American journal of psychiatry	174	12	1175–1184	OBJECTIVE Exposure therapy is an effective treatment for posttraumatic stress disorder (PTSD), but a comprehensive, emotion-focused perspective on how psychotherapy affects brain function is lacking. The authors assessed changes in brain function after

<p>V.; Harvey, Meredith; Peng, Kathy K.; Weiss, M. Elizabeth; Thompson, Allison L.; Zack, Sanno E.; Mills-Finnerty, Colleen E.; Rosenberg, Benjamin M.; Edelstein, Raleigh; Wright, Rachael N.; Kole, Carena A.; Lindley, Steven E.; Arnow, Bruce A.; Jo, Booil; Gross, James J.; Rothbaum, Barbara O.; Etkin, Amit</p>		<p>Function in PTSD</p>				<p>prolonged exposure therapy across three emotional reactivity and regulation paradigms.</p> <p>METHOD Individuals with PTSD underwent functional MRI (fMRI) at rest and while completing three tasks assessing emotional reactivity and regulation. Individuals were then randomly assigned to immediate prolonged exposure treatment (N=36) or a waiting list condition (N=30) and underwent a second scan approximately 4 weeks after the last treatment session or a comparable waiting period, respectively.</p> <p>RESULTS Treatment-specific changes were observed only during cognitive reappraisal of negative images. Psychotherapy increased lateral frontopolar cortex activity and connectivity with the ventromedial prefrontal cortex/ventral striatum. Greater increases in frontopolar activation were associated with improvement in hyperarousal symptoms and psychological well-being. The frontopolar cortex also displayed a greater variety of temporal resting-state signal pattern changes after treatment. Concurrent transcranial magnetic stimulation and fMRI in healthy participants demonstrated that the lateral frontopolar cortex exerts downstream influence on the ventromedial prefrontal cortex/ventral striatum.</p> <p>CONCLUSIONS Changes in frontopolar function during deliberate regulation of negative affect is one key mechanism of adaptive psychotherapeutic change in PTSD. Given that frontopolar connectivity with ventromedial regions during emotion regulation is enhanced by psychotherapy and that the frontopolar cortex exerts downstream influence on ventromedial regions in healthy individuals, these</p>

							findings inform a novel conceptualization of how psychotherapy works, and they identify a promising target for stimulation-based therapeutics.
Forand, Nicholas R.; Feinberg, Jason E.; Barnett, Jeffrey G.; Strunk, Daniel R.	2019	Guided internet CBT versus "gold standard" depression treatments: An individual patient analysis	Journal of clinical psychology	75	4	581–593	<p>OBJECTIVE Guided, computerized cognitive behavioral therapy delivered over the internet (iCBT) is a promising treatment for depression. However, comparisons to "gold standard" treatments and comparators, such as structured psychotherapy, medications, or pill placebo are rare. We compare the results of an 8-week trial of guided iCBT to outcomes from two trials of depression treatment, Penn-Vandy and U. Washington, using individual patient data.</p> <p>METHOD We adjusted for sample differences by restricting the iCBT sample to randomised controlled trial (RCT) inclusion criteria and using propensity scores. Three separate samples were included in analyses: iCBT trial (N = 89), Penn-Vandy (N = 240), and U. Washington (N = 241). Continuous outcomes were analyzed with linear-mixed models and noninferiority analyses were conducted for iCBT versus the psychotherapy conditions. The primary outcomes were attrition, remission, and the Hamilton Rating Scale for Depression.</p> <p>RESULTS Dropout was greater in iCBT than in CT, medications, placebo (Penn-Vandy), and CT and BA (U. Washington), but the rates of remission were similar. In continuous analyses, iCBT was superior to placebo in both RCTs and most analyses indicated no difference between iCBT and the active treatments.</p> <p>CONCLUSIONS Guided iCBT appears not inferior to "gold standard" treatments for depression and is superior to placebo.</p>

							Weaknesses include a lack of randomization, unblinded assessments, and a shorter "frame of treatment" in the iCBT sample.

Foroughe, Mirisse; Browne, Dillon T.; Thambipillai, Prakash; Cordeiro, Kristina; Muller, Robert T.	2023	Brief emotion-focused family therapy: A 12-month follow-up study	Journal of marital and family therapy	49	2	394–410	This study provides a 12-month follow-up evaluation of caregivers after participating in a 2-day Emotion-focused family therapy (EFFT) intensive, a brief intervention for caregivers of youth struggling with mental health difficulties. Caregivers (N = 498) of children (N = 337) completed measures of caregiver self-efficacy and child mental health difficulties 1 week before the intervention, immediately after the intervention, and at 4, 8, and 12-month follow-ups. Piecewise latent trajectory models revealed that parental self-efficacy showed a large

							immediate increase following the intervention, $\beta = 1.61$ (1.32, 2.14), and although this effect was attenuated by 4 months, $\beta = -0.77$ (-1.31, -0.52), it did not change further by 12 months. Reductions in child mental health difficulties were observed by 4 months, $\beta = -0.54$ (-0.77, -0.37), and remained stable through the 12-month follow-up. Caregivers reporting more increases in self-efficacy also reported greater reductions in their children's symptoms at 4 and 12 months.
Foroughe, Mirisse; Stillar, Amanda; Goldstein, Laura; Dolhanty, Joanne; Goodcase, Eric T.; Lafrance, Adele	2019	Brief Emotion Focused Family Therapy: An Intervention for Parents of Children and Adolescents with Mental Health Issues	Journal of marital and family therapy	45	3	410–430	This study evaluated the 2-day intensive modality of Emotion Focused Family Therapy (EFFT). The intervention attempts to prepare parents to take a primary role in their child's recovery from a range of mental health issues. One hundred and twenty-four parents completed the intervention and provided data a week prior to intervention, post-intervention and at 4-month follow-up. Results include significantly reduced parent blocks and increased parental self-efficacy in relation to involvement in their child's recovery, as well as significant improvement in child symptomatology. The findings confirm positive results from an earlier pilot study involving eating disorders and demonstrate the potential for EFFT as an intervention for a range of clinical problems in children and youth.
Forrest, Lauren N.; Franko, Debra L.; Thompson-Brenner, Heather; Grilo, Carlos M.	2023	Examining changes in binge-eating disorder network centrality and structure in patients treated with cognitive-	The International journal of eating disorders	56	5	944–955	OBJECTIVE A sizeable minority of patients with binge-eating disorder (BED) do not fully respond to evidence-based treatments. Evidence to guide refinements of treatments is needed. Conceptualizing BED as arising from a network of symptom-to-symptom interactions allows for identification of the most strongly connected symptoms, which could inform intervention targets. This study estimated networks of BED features at pretreatment and

		<p>behavioral therapy versus interpersonal psychotherapy</p>				<p>posttreatment to assess whether cognitive behavioral therapy (CBT) and interpersonal psychotherapy (IPT) differentially impacted the interrelationships of BED symptoms/features.</p> <p>METHODS Participants were 392 adults (83% women, 88% white) with BED who received CBT (n = 236) or IPT (n = 156) and assessed at pretreatment and posttreatment. Networks were estimated across timepoints and treatments. Expected influence (EI) was calculated; symptoms with the highest EI have the most strong and frequent associations with other symptoms. We also assessed whether the symptoms with the highest and lowest EI predicted posttreatment remission indicators.</p> <p>RESULTS In the CBT and IPT networks, shape concern, weight concern, and eating concern had the highest EI at pretreatment and posttreatment. EI significantly increased from pretreatment to posttreatment for some symptoms in CBT but did not change for any symptoms in IPT. Shape concern significantly and positively predicted BED remission indicators in CBT and IPT.</p> <p>CONCLUSIONS CBT and IPT similarly impacted interrelations among BED features. Pretreatment EI predicted posttreatment remission indicators, indicating that pretreatment centrality could signal meaningful intervention targets. Clinical implications and avenues for future research are discussed including how personalized network analysis may advance the understanding of the clinical utility of centrality.</p> <p>PUBLIC SIGNIFICANCE Cognitive behavioral therapy and interpersonal therapy</p>
--	--	--	--	--	--	---

							for binge-eating disorder, which are two leading evidence-based treatments for binge-eating disorder that are quite different in their models and approaches, similarly impacted interrelations among binge-eating disorder symptoms. In addition, the most strongly interconnected symptom predicted indicators of remission. Studying the interrelations among symptoms may provide new insight on how treatments impact symptom relationships and inform intervention targets.
Fortmeier, Paul; Winter, Elena	2017	"An der Schnittstelle von Person und Organisation"	Gesprchpsych otherapie und Personzentrierte Beratung	48	1	8-10	Im Gesprch mit Paul Fortmeier werden aktuelle Trends in der Supervision betrachtet. Zum einen werden fachliche und strukturelle Herausforderungen beleuchtet, zum anderen wird der Beitrag des personzentrierten Ansatzes fr die Entwicklung der Supervision diskutiert.
Fortney, John C.; Rajan, Suparna; Chen, Jessica A.; Campbell, Sarah B.; Nolan, John P.; Wong, Edwin; Sayre, George; Petrova, Valentina; Simons, Carol E.; Reisinger, Heather S.; Schnurr, Paula P.	2023	A mixed-methods evaluation of why an implementation trial failed to engage veterans with posttraumatic stress disorder in trauma-focused psychotherapy	J. Traum. Stress (Journal of Traumatic Stress)	36	4	762-771	Abstract An effectiveness trial found that telemedicine collaborative care for posttraumatic stress disorder (PTSD) significantly increased engagement in trauma-focused psychotherapy (TFP) and improved PTSD symptoms. However, in a subsequent implementation trial, very few veterans enrolled in collaborative care initiated TFP. We conducted a mixed-methods evaluation to determine why veterans did not initiate TFP in the implementation trial. After conducting chart reviews of 1,071 veterans with PTSD enrolled in collaborative care, patients were categorized into four mutually exclusive TFP groups: TFP not discussed; TFP discussed, declined; TFP discussed, did not decline; and TFP initiated. We conducted semistructured interviews with 43 unique patients and 58 unique providers (i.e., care managers and mental health specialists). Almost half (48.6%) of the veterans had no documentation of discussing TFP with their care manager; another 28.9% discussed it but declined. Most veterans (77.1%) had an encounter with a

							<p>mental health specialist, 36.8% of whom never discussed TFP, and 35.7% of whom discussed it but declined. Providers reported that many veterans were not able, willing, or ready to engage in TFP and that non-trauma-focused therapies were better aligned with their treatment goals. Veterans gave numerous reasons for not initiating TFP, including having bad prior experiences with TFP and wanting to avoid thinking about past traumatic experiences. Commonly cited reasons for noninitiation were providers never discussing TFP with veterans and veterans declining TFP after discussing it with their provider. Interventions, such as shared decision-making tools, may be needed to engage providers and patients in informed discussions about TFP.</p>
Fosha, Diana; Thoma, Nathan	2020	Metatherapeutic processing supports the emergence of flourishing in psychotherapy	Psychotherapy		19 39- 15 36(Ele ctr oni c), 00 33- 32 04(Pri nt)	323–339	<p>Psychotherapy has primarily focused on ameliorating symptoms and psychopathology. This is in contrast to positive psychology, which has focused on bringing about what Keyes (2002) has called “flourishing.” Accelerated experiential dynamic psychotherapy (AEDP) seeks to bridge the two traditions by both relieving suffering through processing painful negative emotions to completion and then going on to foster flourishing, in session and beyond, through a technique called metatherapeutic processing. After a brief summary of the AEDP approach, the aim of this article is to elaborate specifically on metatherapeutic processing, where a focus on savoring and exploring the positive affects that accompany the change process itself can set into motion an upward spiral of positive affect that broadens and builds the treatment’s effectiveness. We provide a how-to primer on metatherapeutic processing as well as annotated transcript material from three cases to illustrate the application of the technique. We describe</p>

							how metatherapeutic processing can organically foster, from the bottom-up, positive feeling states labeled transformational affects, such as gratitude, love, hope, curiosity, and zest, freeing up these vital energies that were latent within the client. We go on to propose that although metatherapeutic processing was conceived of within the framework of AEDP, it is a technique that can be integrated into a wide variety of psychotherapies, to activate flourishing in session and beyond. (PsyInfo Database Record (c) 2020 APA, all rights reserved)
Fox, Erin; Economos, Alexa; Potvin, Noah	2022	Assessment and Clinical Decision-Making During Imminent Death in Hospice Music Therapy	Journal of music therapy	59	1	6-35	Assessment is a critical aspect of treatment planning, and while there exist standards for facilitating music therapy assessments in a variety of clinical settings, no such standards exist for music therapists in hospice and palliative care. This gap in knowledge, which limits music therapists' ability to provide patients and caregivers best practices promoting supported movement through the dying process, becomes particularly problematic when assessing patients who are imminently dying with a 24-72 hour prognosis. To further develop and define assessment and clinical decision-making processes used by music therapists in hospice and palliative care, the authors used a constructivist grounded theory and situational analysis methodology to analyze interviews of 15 hospice music therapists. The resulting theoretical model describes an ongoing process of assessment and clinical decision-making shaped by participants' individual epistemologies. Epistemologies were comprised of 5 ways of knowing, which were termed experiential, personal, musical, ethical, and integral, and provided participants critical foundations for their practice. The results support a development of a model for reflective

						practice as well as continued research on epistemological foundations of clinical practice.
Fraire, Amy; Tiwari, Dhriti; Hinger, Cassandra; Leeper, Emily; Agorsor, Courtney; Hughitt, Rachel; Coleman, Jeremy; Sinha, Sree; Porter, Emma Freetly; DeBlaere, Cirleen; Davis, Don E.; Owen, Jesse	2023	Observer and client perceptions of therapist multicultural orientation in a jail setting	Journal of Psychotherapy Integration	33	4	Few studies have examined cultural factors in the context of jail-based psychotherapy. Given that incarcerated populations often consist of larger proportions of racial/ethnic minoritized groups and lower socioeconomic status individuals, more culturally oriented services could improve treatment outcomes. The multicultural orientation (MCO) framework could maximize psychotherapy outcomes with this clinical population; however, previous research has not examined MCO in a jail-based treatment setting. Additionally, research has historically utilized client and therapist perspectives of therapeutic alliance and cultural processes during psychotherapy, with observer perspectives receiving minimal attention. This study contributes to existing literature on jail-based psychotherapy and therapist MCO by investigating client and observer perspectives of therapists' demonstration of cultural humility, missed cultural opportunities (i.e., a therapist's engagement in cultural discussions during session), and therapeutic alliance. Fifty-eight adult (M = 35.18 years; SD = 10.52) clients participated in this study. Participants were predominately men (84.5%) and self-identified as White (27.6%), Multiracial (24.1%), African American/Black (20.7%), or Latine/Hispanic (20.7%). Results indicated that both clients and observers indicated a stronger therapeutic alliance if they perceived the therapist as more culturally humble. Clients indicated lower alliance when they perceived the therapist to have missed more cultural opportunities during session. There was no relationship between client and observer ratings of therapist cultural humility, missed cultural

						opportunities, or therapeutic alliance. This study provides evidence regarding the potential utility of comparing client and observer perspectives of therapeutic alliance and cultural processes in psychotherapy, as well as contributes to the scarcity of research on psychotherapy treatment in jail settings. Francis, Emma R.; Smith, Jared G.; Qayyum, Mustabshira; Lee, Jessica;	2020	Biographical films as a person-centered approach to	Journal of clinical psychology	76	1	137-145	<p>OBJECTIVE: Neuropsychiatric symptoms are a major component of dementia irrespective of severity or subtype. We aimed to determine the feasibility of biographical films to reduce neuropsychiatric symptoms in people with moderate to severe dementia over a 32-</p>

Woodgate, Philip; Lawrence, Robert M.		reduce neuropsychiatric symptoms of dementia in residential care: A feasibility study					week period. METHOD: A total of 11 people with dementia situated in a residential care home took part in this mixed-method feasibility study. Carers reported neuropsychiatric symptoms of residents at three time-points, and their experience of the study was obtained at a feedback session. RESULTS: There was a significant reduction in neuropsychiatric symptoms in residents with neuropsychiatric impairment from baseline to the end of study ($p = .042$; $d = .98$). Thematic analysis identified three major themes: Triggered memories, knowledge gained to support care, and perceived changes in the resident. CONCLUSION: The findings suggest that it is feasible to use biographical films long-term to reduce neuropsychiatric symptoms of dementia, alongside routine care.
Franke, Irina; Speiser, Oskar; Dudeck, Manuela; Streb, Judith	2020	Clinical Ethics Support Services Are Not as Well-Established in Forensic Psychiatry as in General Psychiatry	Frontiers in psychiatry	11		186	Background: Mental health care professionals deal with complex ethical dilemmas that involve the principles of autonomy, justice, beneficence, and non-maleficence. Such dilemmas are even more prominent in forensic mental health care, where the restriction of personal rights is legitimated not only by patient well-being but also by public safety interests. Little is known about either the use of formal ethics support services or specific ethical needs in forensic mental health care. Knowledge about the current structures and how they compare with those in general psychiatry would help to identify the most important ethical issues and to analyze whether there are unmet needs that might require specific ethics support. Methods: We performed a survey study in all general psychiatric and forensic psychiatric inpatient departments in Germany. The aims were to compare the availability and functioning of clinical ethics structures and to identify specific ethical needs in inpatient forensic

							and general mental health care. Results: Clinical ethics support was available in 74% of general psychiatric hospitals but in only 43% of all forensic psychiatric hospitals and 25% of those offering treatment for offenders with substance use disorders. Most ethics support services were interdisciplinary. The most frequently requested retrospective and prospective ethics consultations were on issues of omission and termination of treatment, coercive measures, and advance directives. Among the hospitals without access to ethics support, 71% indicated a need for training in ethics. Discussion: Our results show that ethics consultation is well established in general psychiatry, but less so in forensic psychiatry. Mental health care professionals in forensic psychiatry seem to have a need for ethics support and training in clinical ethics. We also found a difference in access to ethics structures between hospitals that treat mentally disordered offenders and those that treat offenders with substance use disorders. Further research should focus on how ethics support can be comprehensively implemented in forensic mental health care and how this might improve treatment quality and patient and staff well-being.

Frankish, Pat	2021	Psychotherapy and Attachment Dynamics in People with Intellectual Disabilities				130–150	Summary This chapter provides a personal overview of what has happened in the provision of attachment-based psychotherapy for people with intellectual disabilities (ID) over the last 30 years. It includes descriptions of the approaches and models of understanding that have informed and helped the author's work. There is a distinction to be made between psychotherapy that is provided on an individual, one-to-one basis, psychotherapy provided on a group basis and a psychotherapeutic environment that is provided on an indirect basis with an organizational focus. Organizational approaches are more commonly used with people with more severe disabilities. People with limited cognitive and language abilities have a range of emotions that need an opportunity for expression. An attachment-based intervention, whether it is individual therapy or something less direct, has been shown to be effective and should be accessible to everyone who would benefit from it.
Frankl, Viktor E.	2017	Wer ein Warum zu leben hat. Lebenssinn und Resilienz					Lebenssinn und Resilienz stehen im Mittelpunkt der von V. Frankl (1905 bis 1997) begründeten Logotherapie, seiner Auseinandersetzung mit Holocaustüberlebenden und seiner kritischen Haltung gegenüber der inneren Leere der modernen Konsumgesellschaft. Quasi als Einladung zur Neuentdeckung des großen Humanisten werden Texte von Frankl aus sechs Jahrzehnten dokumentiert. Sie zeigen den Brückenschlag auf, den Frankl zwischen Psychologie und philosophischer Lebenskunst vollzogen hat. - Inhalt:

Franqu, Fritjof von; Schmidt, Claudia	2023	Klärungsorientierte Psychotherapie				<p>Im nachfolgenden Kapitel errtern wir die Anwendungsmöglichkeiten der Klärungsorientierten Psychotherapie (KOP) als ein Psychotherapieverfahren im forensischen Kontext. Wir skizzieren zunächst die Grundlagen der KOP und stellen beispielhaft ausgewählte Interventionen vor, um im zweiten Teil kurz die inhaltlichen Besonderheiten einer forensischen Psychotherapie zu charakterisieren. Anhand der jeweiligen Kategorien von dynamischen Risikofaktoren bei Gewalt- und Sexualdelinquenz stellen wir konkret dar, wie</p>

							die hier vorgestellten Interventionen forensisch-therapeutisch genutzt werden können. Abschließend diskutieren wir, welche Aspekte einer forensischen Psychotherapie durch die KOP gut abgedeckt werden, welche allerdings auch offen bleiben und ggf. durch Interventionen anderer Anstze ergänzt werden müssen. (c) Der/die Autor(en), exklusiv lizenziert an Springer Fachmedien Wiesbaden GmbH
Franqu, Fritjof von; Schwarze, Claudia	2021	Klrungsorientierte Psychotherapie und Forensische Psychotherapie	Forensische Psychiatrie und Psychotherapie	29	1	42–64	Erörtert werden die Anwendungsmöglichkeiten der Klrungsorientierten Psychotherapie (KOP) im forensischen Kontext. Zunächst wird ein Klassifikationsmodell therapeutischer Interventionen vorgestellt, in das sich die spezifischen Strategien der KOP einordnen lassen. Anschließend werden für jede Ebene des Modells Interventionen benannt, die im Rahmen der KOP entwickelt oder ergänzt wurden, ohne diese jedoch im Einzelnen zu konkretisieren. Stattdessen wird auf die entsprechende Literatur verwiesen. Im dritten Teil der Arbeit werden die inhaltlichen Besonderheiten forensischer Psychotherapie skizziert, wobei eine Fokussierung auf Gewalt- und Sexualdelinquenz erfolgt. Anhand der jeweiligen Kategorien von dynamischen Risikofaktoren wird dann dargestellt, welche Strategien der KOP während einer forensischen Psychotherapie genutzt werden können. Abschließend wird diskutiert, welche Aspekte einer forensischen Psychotherapie durch die KOP gut abgedeckt werden und welche offen bleiben und ggf. durch Interventionen anderer Anstze ergänzt werden müssen.
Frantz, Inga; Pedersen, Anya; Lincoln, Tania M.	2018	Psychotherapeutische Behandlungsan	Psychotherapeut	63	4	329–347	Zur Behandlung von psychotischen Störungen wird in vielen Leitlinien - neben der medikamentösen Therapie - Psychotherapie empfohlen. In der aktuellen Leitlinie der Deutschen Gesellschaft für Psychologie wurde die

		stze bei Psychosen					Wirksamkeit folgender psychotherapeutischer Verfahren bewertet: psychodynamische Therapie, Gesprächspsychotherapie, kognitive Verhaltenstherapie (KVT, einschließlich der "Dritte-Welle"-Verfahren), Psychoedukation, verschiedene Fertigkeitentrainings und Familieninterventionen. Diese Verfahren werden im vorliegenden Beitrag vorgestellt, und ihre empirische Evidenz im Hinblick auf verschiedene Zielvariablen wird beleuchtet. Als Therapieverfahren mit überzeugender Evidenzbasis erweisen sich die KVT zur Reduktion der Symptomatik und psychoedukative Familieninterventionen mit Fertigkeitentrainings zur Verringerung der Rückfallwahrscheinlichkeit. Konkrete Empfehlungen zur Indikationsstellung werden abgeleitet und das therapeutische Vorgehen anhand von Beispielen konkretisiert.
FREDERIKSEN, CHRISTINA; SOLBAKKEN, O. ANDRÉL.E.; LICHT, RASMUS W.; JØRGENSEN, CARSTEN RENÉ; RODRIGO-DOMINGO, MARIA; KJAERSDAM TELLÉUS, G. R.Y.	2021	Emotional dysfunction in avoidant personality disorder and borderline personality disorder: A cross-sectional comparative study	Scandinavian J Psychology (Scandinavian Journal of Psychology)	62	6	878–886	According to the literature, avoidant personality disorder (APD) is often overlooked in research on personality disorders. In the present study, patients with APD were compared to patients with borderline personality disorder (BPD) with respect to emotional dysfunction. Emotional dysfunction was operationalized through the Affect Integration Inventory. Sixty-one patients receiving treatment at specialized outpatient hospital facilities for either BPD (n=?25) or APD (n=?36) (Diagnostic and Statistical Manual of Mental Disorders, fifth edition) were included in a cross-sectional study. Supporting our expectations of no difference in the global capacity for affect integration between groups, the estimated difference was 0.00 (95% confidence interval [CI] [?0.53, 0.53]). On the other hand, the expected increased dysfunction in APD regarding Expression could not be confirmed. Furthermore, problems with specific affects

							distinguished the groups; integration of Interest was worse in APD ($p=?0.01$), whereas integration of Jealousy was worse in BPD ($p=?0.04$). In terms of prototypical modes of experiencing affects, APD was characterized by decreased access to the motivational properties of Interest ($p?<?0.01$), while BPD was more driven by Interest ($p?<?0.01$), Anger ($p?<?0.01$), and Jealousy ($p?=?0.01$). In conclusion, even though the two disorders are characterized by similar overall levels of emotional dysfunction, they differ systematically and predictably regarding specific affects and modes of experiencing. These findings carry implications for the understanding of emotional dysfunction in APD and BPD, suggesting specific areas of emotional dysfunction that could be targeted in tailored psychotherapeutic interventions.
Frei-Landau, Rivi; Tuval-Mashiach, Rivka; Silberg, Tamar; Hasson-Ohayon, Ilanit	2020	Attachment to God as a mediator of the relationship between religious affiliation and adjustment to child loss	Psychological Trauma: Theory, Research, Practice, and Policy	12	2	165–174	Objectives: The loss of a child is a traumatic life event. While bereavement research has examined the roles of both interpersonal attachment and religiosity in coping with loss, only a handful of studies have addressed the concept of attachment to God (ATG). The current study examined ATG's role as a mediator in the relationship between religious affiliation (RA) and adjustment to child loss. Method: Seventy-seven bereaved parents (68% women; average age, 55 years) were administered questionnaires referring to RA, ATG, and adjustment to loss (Two-Track Bereavement Questionnaire-TTBQ_70). Results: The hypothesized mediation model was confirmed. Conclusions: The findings highlight the need to examine internal religion-related variables, such as ATG, while addressing religion and loss. From a clinical perspective, the findings may help therapists implement culturally sensitive practice as a part of spiritually informed psychotherapy. Enhancing therapists' familiarity

						with the client's internal constructs will enable a better evaluation and accommodation of therapy when working with bereaved parents. (PsycINFO Database Record (c) 2020 APA, all rights reserved)	
Freire, Elizabeth; Williams, Christopher; Messow, Claudia-Martina; Cooper, Mick; Elliott, Robert; McConnachie, Alex; Walker, Andrew; Heard, Deborah; Morrison, Jill	2015	Counselling versus low-intensity cognitive behavioural therapy for persistent sub-threshold and mild depression (CLICD): a pilot/feasibility randomised controlled trial	BMC psychiatry	15		197	<p>BACKGROUND</p> <p>Persistent depressive symptoms below the threshold criteria for major depression represent a chronic condition with high risk of progression to a diagnosis of major depression. The evidence base for psychological treatments such as Person-Centred Counselling and Low-Intensity Cognitive Behavioural Therapy for sub-threshold depressive symptoms and mild depression is limited, particularly for longer-term outcomes.</p> <p>METHODS</p> <p>This study aimed to test the feasibility of delivering a randomised controlled trial into the clinical and cost effectiveness of Low-Intensity Cognitive Behavioural Therapy versus Person-Centred Counselling for patients with persistent sub-threshold depressive symptoms and mild depression. The primary outcome measures for this pilot/feasibility trial were recruitment, adherence and retention rates at six months from baseline. An important secondary outcome measure was recovery from, or prevention of, depression at six months assessed via a structured clinical interview by an independent assessor blind to the participant's treatment condition. Thirty-six patients were recruited in five general practices and were randomised to either eight weekly sessions of person-centred counselling each lasting up to an hour, or up to eight weeks of cognitive-behavioural self-help resources with guided telephone support sessions lasting 20-30 minutes each.</p> <p>RESULTS</p>

							<p>Recruitment rate in relation to the number of patients approached at the general practices was 1.8 %. Patients attended an average of 5.5 sessions in both interventions. Retention rate for the 6-month follow-up assessments was 72.2 %. Of participants assessed at six months, 71.4 % of participants with a diagnosis of mild depression at baseline had recovered, while 66.7 % with a diagnosis of persistent subthreshold depression at baseline had not developed major depression. There were no significant differences between treatment groups for both recovery and prevention of depression at six months or on any of the outcome measures.</p> <p>CONCLUSIONS</p> <p>It is feasible to recruit participants and successfully deliver both interventions in a primary care setting to patients with subthreshold and mild depression; however recruiting requires significant input at the general practices. The evidence from this study suggests that short-term Person-Centred Counselling and Low-Intensity Cognitive Behaviour Therapy are potentially effective and their effectiveness should be evaluated in a larger randomised controlled study which includes a health economic evaluation.</p> <p>TRIAL REGISTRATION</p> <p>Current Controlled Trials ISRCTN60972025 .</p>
Freiwald, Anja; Quiring, Juliane; Neuse, Yvonne	2018	ber den Umgang mit therapeutischen Anliegen in der Beratung Studierender	Verhaltenstherapie und psychosoziale Praxis	50	3	601-616	<p>Nach einer theoretischen Einfhrung in die berscheidungen und die Grenzen zwischen Beratung und Therapie wird anhand von zwei Beispielen dargestellt, wie in der Beratung von Studierenden mit therapeutischen Anliegen bzw. Bedarfen umgegangen werden kann. Dabei wird deutlich, wie drei wesentliche Aspekte des Lerncoaching-Angebots an der Ostfalia Hochschule fr angewandte Wissenschaften,</p>

							Fachhochschule Braunschweig/Wolfenbüttel - (1) der niedrigschwellige Zugang, (2) die hohe Flexibilität bei der zeitlichen Gestaltung sowie (3) die anliegenorientierte und personenzentrierte Vorgehensweise der Lerncoaches - dazu beitragen, dass betroffene Studierende ihren therapeutischen Bedarf im beratenden Prozess erkennen und gegebenenfalls weitere Schritte einleiten können. Durch diese wichtige "Trichter"-Funktion des Lerncoachings werden Befürchtungen gegenüber einer therapeutischen Behandlung und deren Folgen für das eigene Studium und die berufliche Zukunft abgebaut und neue Wege und Lösungen eröffnet.
Freudenberg, David; Weiland-Heil, Karoline; Sachse, Rainer	2018	Effekte klerungsorientierter Psychotherapie bei Klientinnen und Klienten mit Persönlichkeitsstörungen					Die Effektivität der klerungsorientierten Psychotherapie (KOP) bei Klientinnen und Klienten mit Persönlichkeitsstörungen wird untersucht. Dabei wurden zwei Hypothesen überprüft: (1) Die KOP ist eine effektive Therapieform für die Behandlung von Interaktionsstörungen (IS). (2) Das Ausmaß interpersoneller Probleme kann durch ein negatives Selbstschema vorhergesagt werden. Das Selbstschema ist hierbei durch niedrige Selbstakzeptanz und eine geringe Selbstwirksamkeitserwartung operationalisiert. Ausgewertet wurden Fragebogendaten (Pr-Post-Vergleich) von 688 Klienten einer Institutsambulanz für Psychotherapie (narzisstischer IS N=110, für erfolglose narzisstische IS N=207, für histrionische IS N=160, erfolglos histrionische IS N=162, dependente IS N=48). Insgesamt betrachtet konnten vorherige Befunde der Effektivitätsforschung hinsichtlich der Effektivität der KOP bei IS in der Pr-Post-Testung repliziert werden. Es wurden signifikante Ergebnisse für alle eingesetzten Inventare und ebenfalls mittlere bis hohe Effektstärken gefunden. In Bezug auf die formulierte Fragestellung nach einem regressiven Zusammenhang

							zwischen interpersonellen Problemen und einem negativen Selbstschema zeigte sich ein signifikant negativer Zusammenhang mit ausreichend erklärter Varianz von 39 Prozent. Demnach lie sich für die vorliegende Stichprobe der Schluss ziehen: Je stärker negative Selbstschema der Klienten mit diagnostizierter IS ausgeprägt sind, operationalisiert durch die Selbstwirksamkeitserwartung und Selbstakzeptanz, desto größer sind interpersonelle Probleme.
Frhlich-Gildhoff, Klaus; Rnnau-Bse, Maike	2018	Resilienz, Resilienzfrderung und Personenzentrierter Ansatz	Gesprchpsychotherapie und Personenzentrierte Beratung	49	2	62–68	Aufgezeigt werden die grundlegenden Aspekte des Resilienzkonzeptes, seine Bezüge zum personenzentrierten Ansatz und seine praktische Umsetzung in Form eines Präventionsprogramms für Kindertageseinrichtungen und Grundschulen. Die Entwicklung von Resilienz resultiert der vorgenommenen Definition folgend aus einem Zusammenspiel von Schutz- und Risikofaktoren, die zu einer erfolgreichen Bewältigung von Entwicklungsaufgaben, Krisen und Belastungen führen. Sechs Resilienzfaktoren werden hierbei aufgeführt und Parallelen zum personenzentrierten Ansatz herausgearbeitet. Darauf aufbauend wird ein Mehrebenenansatz zur Resilienzfrderung von Kindern vorgestellt und auf Evaluationsergebnisse verwiesen. Hierbei wurden positive Effekte einer ressourcenorientierten und resilienzfrdernden Pädagogik auf Ebene der Kinder, der Eltern und der pädagogischen Fachkräfte beobachtet.
Frhlich-Gildhoff, Klaus; Rnnau-Bse, Maike; Brandes, Petra; Siegrist, Ulrich; Winter, Elena;	2018	SchwerpunkttHEMA: Krisen meistern und Potenziale entfalten: Resilienz im	Gesprchpsychotherapie und Personenzentrierte Beratung	49	2	62–79	Die Verbindung von personenzentriertem Ansatz und dem Konzept individueller bzw. organisationaler Resilienz wird für verschiedene Zielgruppen diskutiert. Neben der Resilienzfrderung in der kindlichen Entwicklung, im Führungskräfte training, in der Organisationsentwicklung und in der personenzentrierten Familientherapie werden

Lieb, Maria; Ziebertz, Torsten; Hher, Friederike		Personzentrierte n Ansatz. (Mit 5 Einzelbeitrgen)					Aspekte der Selbstfrsorge in der Beratung angesprochen. Inhalt - (1) K. Frhlich-Gildhoff und M. Friedl, Nadine; Berger, Thomas; Krieger, Tobias; Caspar, Franz; grosse Holtforth, Martin	2020	Using the Personalized Advantage Index for individual treatment allocation to cognitive behavioral therapy (CBT) or a CBT with integrated exposure and emotion- focused elements (CBT- EE)	Psychotherapy Research	30	6	763-775	Even though different psychotherapeutic interventions for depression have shown to be effective, patients suffering from depression vary substantially in their treatment response. The goal of this study was to answer the following research questions: (1) What are the most important predictors determining optimal treatment allocation to cognitive behavioral therapy (CBT) or CBT with integrated exposure and emotion-focused elements (CBT-EE)?, and (2) Would model-determined treatment allocation using this predictive information result in better treatment outcomes? Bayesian Model Averaging (BMA) was applied to the data of a randomized controlled trial comparing the efficacy of CBT and CBT-EE in depressive outpatients. Predictions were made for every patient for both treatment conditions and an optimal versus a suboptimal treatment was identified in each case. An index comparing the two estimates, the Personalized Advantage Index (PAI), was calculated. Different predictors were found for both conditions. A PAI of 1.35 BDI-II points for the two conditions was found and 46% of the sample was predicted to have a clinically meaningful advantage in one of the therapies. Although the utility of

							the PAI approach must be further confirmed in prospective research, the present study study promotes the identification of specific interventions favorable for specific patients.
Friedman, Robert	2017	The Theory and Art of Child Psychotherapy: A Corrective Developmental Approach	Psychoanalytic review	104	5	561–593	The history of child psychotherapy is sketched from the psychoanalytic pioneers Anna Freud and Melanie Klein to the popular "nondirective" approach of Virginia Axline. The author's approach to child psychotherapy, based on contemporary psychoanalytic theories, allows the therapist to play any parental role that helps to repair developmental deficiencies and conflicts. These include nurturing, supporting, mirroring, role modeling, challenging, and limit setting. Following Winnicott, psychotherapy is conceived as a play space in which therapist and child are both spontaneous. The value of interpretation and insight in child therapy is discussed. There follows a more detailed discussion of three major problem areas in child psychotherapy: handling anger and hostile aggression; handling issues related to sexuality; and handling narcissistic issues of inferiority and shame.
Frögéli, Elin; Rudman, Ann; Gustavsson, Petter	2019	Preventing stress-related ill health among future nurses: Effects over 3 years	International Journal of Stress Management		15 73- 34 24(Ele ctr oni c), 10 72- 52 45(272–286		In 2011, a randomized controlled trial with a sample of 113 nursing students and a group intervention consisting of six 2-hr sessions based on acceptance and commitment training (ACT) to prevent symptoms of burnout was initiated. Measures included the process variables of mindful awareness and experiential avoidance and the outcome variables of perceived stress and burnout. The current study presents data from 1, 2, and 3 years post intervention, investigating the maintenance of the effects. The effects were analyzed using multilevel modeling, including data from six points of measurement (baseline to 3 years after the end of the

					Print)		intervention). In addition, the mediation of effects was investigated. An effect on mindful awareness was maintained during the years following the intervention as indicated by a statistically significant group-by-time interaction and between-groups differences up to 2 years after the intervention. The group-by-time interactions for experiential avoidance, perceived stress, and burnout did not reach statistical significance, but the between-groups difference for perceived stress at 1 year after the intervention was statistically significant, and the effect was mediated by change in experiential avoidance. This study provided new information about the long-term effects of an ACT intervention including mediation of effects, suggesting that more research should be directed toward investigating mechanisms of change of ACT interventions and how to design interventions that bring about effects that last over time. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Frohme, Gabriele	2020	Krank durch Krnkung: Posttraumatische Verbitterungsstrung (PTED)	Zeitschrift fr Transaktionsanalyse	37	4	292–306	2022 wird voraussichtlich die neue Diagnose der Posttraumatischen Verbitterungsstrung in der ICD-11 eingefhrt werden. Die Verhaltenstherapeuten aus der Forschungsgruppe um Michael Linden haben viele Patienten mit diesem Strungsbild, vor allen in psychosomatischen Kliniken, untersucht und die Weisheitstherapie als Behandlungsmglichkeit entwickelt. In diesem Artikel wird das Krankheitsbild der Posttraumatischen Verbitterungsstrung vorgestellt und die Weisheitstherapie kurz beschrieben. Auerdem wird aufgezeigt, dass mit transaktionsanalytischen Konzepten ein etwas tiefer greifender Ansatz zur kausalen Behandlung dieser Strung vorhanden ist. Einige dieser transaktionsanalytischen Behandlungsanstze werden skizziert.

Frohme, Gabriele	2017	Psychosomatik und Transaktionsanalyse	Zeitschrift für Transaktionsanalyse	34	1	26–43	Es wird aufgezeigt, wie psychosomatische Erkrankungen mit einem transaktionsanalytischen Ansatz behandelt werden können. Die Transaktionsanalyse bietet bei psychosomatischen Erkrankungen ein ganzheitliches System zur Heilung an. Davon ausgehend, dass der Körper frühere Erfahrungen abgespeichert hat und diese Körpererinnerung unbewusst ist wird sie als Vorlage für das Skript angesehen. Mit der Skriptanalyse liegt ein ganzheitlicher Ansatz vor, der körperliche, psychische, soziale, kulturelle und spirituelle Bereiche mit einbeziehen kann. Zur Lösung von frühen unbewussten Konflikten, wie sie sich in den Engpässen manifestieren, eignet sich der psychodynamische Ansatz besonders. Transaktionsanalyse bietet sich als kausale Behandlungsform bei psychosomatischen Erkrankungen an.
Frohn, Dominic	2016	Mediation: Ein humanistisch-systemisches Verfahren - bewährt in klassischen und hilfreich in innovativen Kontexten	Gesprächspsychotherapie und Personenzentrierte Beratung	47	2	73–78	Theoretische Grundlagen der Prinzipien von Mediation und der Gestaltung des Mediationsprozesses werden beschrieben. Ein Schwerpunkt liegt dabei auf der Haltung von Mediatorinnen und Mediatoren, die humanistische Grundannahmen nach Rogers mit (hypno-)systemischen Ansätzen vereint. Im Weiteren wird die theoretische Basis in verschiedenen Anwendungskontexten konkretisiert. Am Beispiel der Arbeit mit "Regenbogenfamilien" wird das innovative Potential von Mediation verdeutlicht.
Front, Or; Yaffe-Herbst, Lirit; Wiseman, Hadas; Viksman, Polina; Kaplan, Haim; Zilchamano, Sigal	2021	Insight as a dual-perspective construct: Convergence between patients' and professional	Psychotherapy		19-39-1536(Electronic),	372–378	Insight gained by patients during treatment has been theorized to be a central mechanism of change in psychotherapy, but empirical studies examining the association between patients' insight and psychopathological symptoms have produced mixed results. The present study addresses these inconsistencies by investigating convergence between the perspectives of patient and professional evaluator on

		evaluators' perspective on baseline level of insight and on changes in insight			00 33- 32 04(Pri nt)		insight and disentangling two potentially distinct components of insight: pretreatment individual differences and changes in insight during treatment. A sample of 393 patients receiving psychodynamic psychotherapy completed pre- and posttreatment measures on symptoms and insight. Professional evaluators evaluated patients' insight based on clinical interviews pre- and posttreatment. Polynomial regression and response surface analyses were used to examine congruence. The results indicate that when there was agreement between the patient and the evaluator on insight, both baseline level of insight and the changes in insight during treatment were found to be related to symptomatic change, although showing different patterns of association. Lower baseline levels of insight were significantly associated with greater symptomatic improvement than were higher levels of insight. At the same time, greater increase in insight during treatment was moderately significantly associated with greater reduction in symptoms, as long as the changes in insight were not minimal. The findings underscore the importance of assessing the congruence between patients' and professional observers' perspectives on patient insight and the potentially distinct roles of between-patients baseline differences and within-patient changes in insight during treatment. Frster, Katharina; Kurtz, Marcel; Konrad, Annika; Kanske, Philipp	2022	Emotional reactivity, emotion regulation, and social emotions in affective	Zeitschrift fr Klinische Psychologie und Psychotherapie	51	1	11–25	Affective disorders, specifically major depressive disorder and bipolar disorders, show high prevalence, relapse rates, and a high likelihood to develop a chronic course. For the past two decades, research has investigated the neural correlates of emotion processing and emotion regulation in patients with affective disorders. Putative

		disorders. Neural models informing treatment approaches					underlying causal mechanisms of dysregulated affect have been informed by knowledge from the intersection of neuroimaging and clinical psychology. More recent investigations also consider processing the role of mostly negative, self-blaming social emotions, which have been linked to treatment resistance and, hence, provide a prolific target for intervention. Several psychotherapeutic treatment approaches already focus on emotion, and here specific knowledge about the mechanisms underlying persistent changes in affect bears the potential to improve the treatment of affective disorders. In this narrative review, we delineate why and how our insights into the neural correlates of emotion processing and regulation can be applied to the treatment of patients with affective disorders.
Frymann, Tomas; Whitney, Sophie; Yaden, David B.; Lipson, Joshua	2022	The Psychedelic Integration Scales: Tools for Measuring Psychedelic Integration Behaviors and Experiences	Frontiers in psychology	13		863247	In this study, we describe the development and initial validation of two psychometric scales for measuring psychedelic integration. Psychedelic integration refers to the post-acute period of time following psychedelic drug administration. We created the Integration Engagement Scale (IES) to capture positive behavioral engagement with integration and the Experienced Integration Scale (EIS) to capture internal aspects of feeling integrated. These scales were developed to measure post-acute psychedelic administration dynamics in order to inform the creation of enhanced integration support and to help refine a general conceptual understanding of the construct of psychedelic integration. The scales are brief and face valid instruments designed for practical use in applied and research settings. Scale items were generated and refined using the Iterative Process Model of scale development, with input from psychedelics experts and clinicians. Content validity, internal structure, and

							reliability were assessed via expert surveys, content validity analysis, cognitive interviewing, convergent validity analysis, exploratory factor analysis, and confirmatory factor analysis. The data indicates the scales are valid and reliable measurements of the behavioral and experiential forms of Psychedelic Integration.
Fuchs, Christian	2021	Der Körper, das Trauma und der Affekt. Theorie und Praxis der Polyvagaltheorie in der Psychotherapie					Die Möglichkeit einer praktischen Umsetzung der Polyvagaltheorie in der psychotherapeutischen Arbeit wird beschrieben. Ausgangspunkt ist die Gestalttherapie in ihrer dialogisch-phänomenologischen Ausrichtung. Die Konzepte der Polyvagaltheorie werden erlutert und zu Dialog, Kontakt und autonomen Körperreaktionen in Beziehung gesetzt. Es wird gezeigt, wie die Theorie durch eine spezifische therapeutische Haltung erfolgreich in der Praxis eingesetzt werden kann. Praxisbeispiele demonstrieren die Anwendung. Dabei wird deutlich, dass auch andere Therapieformen, die ber Kontakt sichere Räume für Betroffene erzeugen können, gleichermaßen für die Anwendung der Polyvagaltheorie geeignet sind. Ziel der Ausfhrungen ist die Schaffung einer Verständnisgrundlage, wie im psychotherapeutischen Prozess gezielt mit autonomen Körperreaktionen gearbeitet werden kann. Gerade bei einem erlebnisorientierten therapeutischen Vorgehen sind diese autonomen Körperreaktionen sehr häufig zu beobachten und können gezielt für die Integration von traumatischem Erleben eingesetzt werden. Die Polyvagaltheorie stellt ein Theoriegebäude vor, das autonome Körperreaktionen in ein Erklärungsmuster einbettet. Insbesondere in der Arbeit am Trauma, aber auch bei anderen seelischen Themenstellungen, sind es zu einem nicht unerheblichen Teil diese unwillkürlichen Reaktionen, die in der Folge zu massiven Schwierigkeiten

							<p>der Affektkontrolle wie Angst- und Panikattacken, Flashbacks, Depressionen, psychosomatischen Problemen und dissoziativen Symptome führen. - Inhalt: (A) Trauma und Autonomes Nervensystem. Fuchs, Thomas	2022	Bilder und Imaginationen vom Körper . Funktion und Wirkung aus gestalttheoretischer Perspektive	Phänomenal	14	1	10-18	<p>Bilder und Imaginationen bestimmen unser Denken und Fühlen mehr als gemeinhin angenommen. In dieser Arbeit wird ihre Funktion und Wirkung anhand gestalttheoretischer Konzepte untersucht und beschrieben. Insbesondere wird der Frage nachgegangen, wie Bilder und Imaginationen zur Selbstvergewisserung, Steuerung und Feinjustierung zwischen phänomenalem Mikrokosmos und Makrokosmos beitragen. Wann sind Bilder hilfreich, wann haben sie negative oder gar destruktive Wirkungen? Eine entscheidende Rolle spielt dabei das Bezugssystem, durch das wesentlich mitbestimmt wird, ob Bilder hilfreich sind oder nicht.</p>

							Daraus leitet sich ab, wie Bilder und Imaginationen therapeutisch genutzt werden können. Anhand von Beispielen essgestörter Menschen wird gezeigt, welche Möglichkeiten bestehen, mit Bildern und Imaginationen zur Entwicklung beizutragen. Ein Sonderfall ist die Hartnäckigkeit, mit der sich Strungen in der Körperwahrnehmung essgestörter Menschen auch nach Überwindung der Ess-Symptomatik halten. Diese ungewöhnliche Persistenz einer körperlichen Imagination wird gesondert betrachtet. Mögliche Hypothesen zur Erklärung dieses Phänomens werden diskutiert und es werden - davon abgeleitet - mögliche Varianten eines therapeutischen Umgangs damit angedeutet.
Fuchs, Thomas	2016	Schmerz lässt nach! Anmerkungen zur psychotherapeutischen Diagnostik und Behandlung von Schmerzzuständen	Gestalt Theory	38	2-3	297-309	Schmerz besitzt die Eigenheit, zum Zentrum des gesamten psychologischen Feldes zu werden. Duncker nennt das in einer frühen Arbeit (1937) die "Dringlichkeit" (urgency) des Schmerzes. Er analysiert experimentell Bedingungen, unter denen sich die Wahrnehmung des Schmerzes verändert. Die Grundthese lautet, dass ein Schmerz umso weniger intensiv erlebt wird, je weniger er im Zentrum des psychologischen Feldes steht. Damit ist auch impliziert, dass sich ein erlebter Schmerz allenfalls relativ zu einem physikalischen Reiz verhält. Das gilt bereits für den akuten Schmerz und erst recht für chronische Schmerzzustände. Eine Erkenntnis, die sich 75 Jahre nach Duncker zumindest in der entsprechenden Fachliteratur durchgesetzt hat, leider noch nicht durchgängig in der Praxis der Schmerzbehandlung. Hier dominiert nach wie vor (sowohl bei Patienten als auch bei Ärzten und Therapeuten) die krampfhaftes Suche nach organischen Ursachen und führt häufig zu Überdiagnostik und Fehlbehandlung. Die Gestalttheorie betont seit jeher die notwendige Unterscheidung von physikalischer Welt und

						<p>erlebter (phnomenaler) Welt (Metzger 1963). Schmerz als seelisches Geschehen scheint insofern besonders geeignet, die Bedeutung eines phnomenologischen Zugangs in der Behandlung zu begrnden. Ein wichtiger Aspekt vor allem beim chronischen Schmerz ist dabei das Bezugssystem, in das der Schmerz eingebettet wird. Zudem soll gezeigt werden, welche Elemente im Fall der Chronifizierung eines Schmerzes eine Rolle spielen und wie diese Elemente in systematischer Weise zur Umstrukturierung des psychologischen Feldes beitragen. Daraus werden Hinweise fr die psychotherapeutische Arbeit abgeleitet.</p>

Fyhn, Tonje; Øverland, Simon; Reme, Silje E.	2021	Predictors of employment in people with moderate to severe mental illness participating in a randomized controlled trial of Individual Placement and Support (IPS)	The International journal of social psychiatry	67	2	150–157	BACKGROUND: Many people with moderate to severe mental illness have a desire to obtain ordinary employment. To aid further development of health and social services for this group, the aim of this study was to examine candidate modifiable and prognostic markers of employment, and moderating effects of group allocation in a clinical trial. METHOD: The sample consists of 327 patients in treatment for mental illness, randomized to Individual Placement and Support (IPS) or treatment as usual (TAU) as part of a clinical trial. Psychosocial and demographic baseline characteristics were included as predictors in log binary regression analyses with employment 18 months after inclusion as the outcome, and group allocation as the moderator (IPS or TAU). RESULTS: Directive emotional support and non-directive instrumental support seemed to positively predict employment, but effects were small. Involuntary hospitalization seemed to be a strong negative predictor of employment. Group allocation did not moderate any main effects. CONCLUSION: Interpretation of the findings suggest that attention should be given to certain aspects of health and social services provided to this target group, and in particular the effect of receiving appropriate types of social support. The findings are novel because social support and involuntary hospitalization do not seem to have been included in previous predictor studies. The results from this study identify new topics for research on employment outcomes for this population.
Fynn, Judith F.; Hardeman, Wendy; Milton,	2020	A scoping review of evaluation	BMC public health	20	1	1000	BACKGROUND: Physical activity and dietary change programmes play a central role in addressing public health priorities. Programme evaluation contributes to

<p>Karen; Jones, Andy P.</p>		<p>frameworks and their applicability to real-world physical activity and dietary change programme evaluation</p>				<p>the evidence-base about these programmes; and helps justify and inform policy, programme and funding decisions. A range of evaluation frameworks have been published, but there is uncertainty about their usability and applicability to different programmes and evaluation objectives, and the extent to which they are appropriate for practitioner-led or researcher-led evaluation. This review appraises the frameworks that may be applicable to evaluation of physical activity and/or dietary change programmes, and develops a typology of the frameworks to help guide decision making by practitioners, commissioners and evaluators. METHODS: A scoping review approach was used. This included a systematic search and consultation with evaluation experts to identify evaluation frameworks and to develop a set of evaluation components to appraise them. Data related to each framework's general characteristics and components were extracted. This was used to construct a typology of the frameworks based on their intended programme type, evaluation objective and format. Each framework was then mapped against the evaluation components to generate an overview of the guidance included within each framework. RESULTS: The review identified 71 frameworks. These were described variously in terms of purpose, content, or applicability to different programme contexts. The mapping of frameworks highlighted areas of overlap and strengths and limitations in the available guidance. Gaps within the frameworks which may warrant further development included guidance on participatory approaches, non-health and unanticipated outcomes, wider contextual and implementation factors, and sustainability. CONCLUSIONS: Our typology and mapping signpost to</p>
------------------------------	--	---	--	--	--	--

							frameworks where guidance on specific components can be found, where there is overlap, and where there are gaps in the guidance. Practitioners and evaluators can use these to identify, agree upon and apply appropriate frameworks. Researchers can use them to identify evaluation components where there is already guidance available and where further development may be useful. This should help focus research efforts where it is most needed and promote the uptake and use of evaluation frameworks in practice to improve the quality of evaluation and reporting.
Gaab, Jens; Ziem, Max; Flckiger, Christoph	2020	Humanistische und experientielle Psychotherapie- verfahren					Humanistische und experientielle Psychotherapieverfahren umfassen verschiedene Therapieansätze, welche mit ihrer Anerkennung einer kongruenten, empathischen und wertschätzenden therapeutischen Beziehung als notwendige und hinreichende Voraussetzung für Veränderungen, ihrem Fokus auf die Erfahrung im therapeutischen Prozess und auf das persönliche Wachstum sowie ihrer expliziten Personzentrierung ein eigenständiges Verständnis- und Vorgehensparadigma darstellen. Ausgehend von frühen empirischen Beobachtungen Carl Rogers und deren Weiterentwicklung haben die humanistischen und experientialen Psychotherapieverfahren fortlaufende Differenzierungen erfahren, wobei hier die motivierende Gesprächsführung und die emotionsfokussierten Psychotherapie als einflussreiche Beispiele zu nennen sind. Die Wirksamkeit von humanistischen und experientialen Psychotherapieverfahren ist empirisch belegt und die angenommenen Wirkmechanismen sind durch die Ergebnisse der Psychotherapieforschung bestätigt. (c) Springer-Verlag GmbH Deutschland

<p>Gablonski, Thorsten-Christian; Herrmann, Pauline Leonie; Lüdemann, Jonas; Andreas, Sylke</p>	<p>2023</p>	<p>Intersession experiences and internalized representations of psychotherapy: A scoping review</p>	<p>Journal of clinical psychology</p>	<p>79</p>	<p>8</p>	<p>1875–1901</p>	<p>INTRODUCTION Between-session processes outside the therapy room and beyond the direct interaction between a therapist and client can play an important role in the psychotherapeutic process and outcome. These processes are called intersession experiences and can be seen as internalized mental representations of therapy and/or therapists. Due to the COVID-19 pandemic, different digital forms of treatment have successfully been implemented and could be relevant even after the end of the COVID-19 pandemic. Therefore, patients' internalized mental representations may become highly relevant in the future.</p> <p>RATIONALE The aim of this study was to conceptually delineate the current state of research on internalized mental representations of therapy or therapists in the period between sessions and to provide an overview of the evidence. In addition, we aimed to identify research gaps to provide a baseline for further research.</p> <p>METHODS For this purpose, we conducted a scoping review to obtain a comprehensive overview of the evidence and to identify the relevant research gaps. We searched PsycArticles, Medline, PsycINFO, and PSYINDEX for publications on internalized mental representations.</p> <p>RESULTS The final sample comprised 30 publications published from 1989 to 2021. Based on the individual study results, it can be assumed that intersession experiences are of central importance for psychotherapeutic treatment. However, the scoping review showed that there was a large gap in knowledge in the research of intersession experiences. All previous research was barely</p>
---	-------------	---	---------------------------------------	-----------	----------	------------------	--

							comparable, and therefore, a generalized statement is not possible. CONCLUSION Future research should provide sufficient information about relevant aspects, such as the setting, therapists, and patients, as these factors are likely to have a significant impact on the outcome. Furthermore, better measurements for the assessment of these processes should be developed.
Gaebel, Wolfgang; Lehmann, I.; Chisholm, D.; Hinkov, H.; Höschl, C.; Kapócs, G.; Kurimay, T.; Tosevski, D. Lecic; Milosavljevic, M.; Nakov, V.; Winkler, P.; Zielasek, J.	2021	Quality indicators for mental healthcare in the Danube region: results from a pilot feasibility study	European archives of psychiatry and clinical neuroscience	271	6	1017–1025	Quality indicators are vital for monitoring the transformation of institution-based mental health services towards the provision of person-centered mental healthcare. While several mental healthcare quality indicators have been identified as relevant and valid, their actual usability and utility for routine monitoring healthcare quality over time is significantly determined by the availability and trustworthiness of the underlying data. In this feasibility study, quality indicators that have been systematically identified for use in the Danube region countries of Bulgaria, the Czech Republic, Hungary, and Serbia were measured on the basis of existing mental healthcare data in the four countries. Data were collected retrospectively by means of the best available, most standardized, trustworthy, and up-to-date data in each country. Out of 21 proposed quality indicators, 18 could be measured in Hungary, 17 could be measured in Bulgaria and in the Czech Republic, and 8 could be measured in Serbia. The results demonstrate that a majority of quality indicators can be measured in most of the countries by means of already existing data, thereby demonstrating the feasibility of quality measurement and regular quality monitoring. However, data availability and usability are scattered across

							countries and care sectors, which leads to variations in the quality of the quality indicators themselves. Making the planning and outputs of national mental healthcare reforms more transparent and evidence-based requires (trans-)national standardization of healthcare quality data, their routine availability and standardized assessment, and the regular reporting of quality indicators.
Gahleitner, Silke Birgitta	2018	Bindung, Beziehung und Einbettung ermöglichen: Anregungen für die Therapie und Beratung mit beziehungsorientierten Menschen	Gesprächspsych otherapie und Personzentrierte Beratung	49	3	132-136	Erörtert wird die Bedeutung einer emotional tragenden, bindungs- und begegnungsorientierten, vertrauensvollen Beziehung in Therapie und Beratung. In der auf einem Vortrag im Rahmen des GwG-Jahreskongresses 2018 basierenden Darstellung wird auf Befunde verwiesen, die zeigen, wie sehr Behandlungserfolge in psychotherapeutischen und psychosozialen Settings von vergangenen und aktuellen Beziehungserfahrungen geprägt sind. Die grundlegenden Mechanismen hierfür werden in der Bindungstheorie, der Vertrauens- und der Netzwerktheorie verortet und durch Interviewpassagen von Frauen mit Ausgrenzungs-, Abwertungs- und Ausbeutungserfahrungen illustriert. Im Anschluss wird die Beziehungsgestaltung im Personenzentrierten Ansatz näher beleuchtet und Parallelen zwischen den Bedingungen des therapeutischen Prozesses und dem Konzept der Feinfühligkeit in der Bindungstheorie herausgestellt. Darüber hinaus wird betont, dass eine authentische und wertschätzende therapeutische Haltung eine stetige Persönlichkeitsentwicklung auf Seiten der Fachkraft erfordert. Zuletzt wird über die konkrete Umsetzung der theoretischen Erkenntnisse in die Praxis reflektiert.
Gahleitner, Silke Birgitta	2018	Trauma					Ausmaß und Ausformung der Folgeerscheinungen nach traumatischen Ereignissen sind abhängig von der Art, den

						Umstnden und der Dauer der traumatischen Einwirkung. Zu den Umstnden zhlt neben dem Entwicklungsstand bei der Traumatisierung insbesondere, ob es vor, whrend oder nach der Traumatisierung schtzende Faktoren gegeben hat. Traumatische Belastungen und Folgeerscheinungen wie die Posttraumatische Belastungsstrung sind daher nicht nur als Konsequenz traumatischer Ereignisse zu verstehen, sondern prinzipiell immer als Versuche, das traumatische Ereignis in der jeweiligen (Lebens-)Situation mglichst gut zu verarbeiten. Bei aller scheinbarer Absurditt und Dysfunktionalitt stehen die dadurch entstehenden Inkongruenzen - zunchst - im Dienst des berlebens. (c) Springer-Verlag GmbH Deutschland
Gahleitner, Silke Birgitta; Hintenberger, Gerhard; Pammer, Barbara	2022	Humanistische Traumatherapie in der Praxis. Biografische Verletzungen verstehen und therapeutisch beantworten				Traumatische Belastungsfolgen sind nach humanistischem Verstdnis Versuche, widrige Lebensereignisse mglichst konstruktiv zu bewltigen. Humanistische Therapieverfahren setzen daher stets an der berlebenskraft und -kreativitt an. Im Dialog mit den Betroffenen werden Einblicke in ihre jeweilige Traumabiografie gewonnen. Eine zentrale Rolle spielt fr den Heilungsprozess auch, ob Betroffenen Anerkennung statt Ausgrenzung, Abwertung und Tabuisierung entgegenkommt. Dies impliziert konsequente Beziehungsorientierung im Therapieprozess. Traumatische Erfahrungen unterliegen lebenslang einem Prozesscharakter. Humanistische Verfahren greifen das damit verbundene Entfaltungspotenzial der Klientinnen und Klienten im therapeutischen Geschehen auf. Aus dem Fundus sechs verschiedener humanistischer Verfahren gibt der Band vielfltige Anregungen fr die therapeutische Praxis. - Inhalt: https://d-nb.info/1243100672/04

Gahleitner, Silke Birgitta; Locher, Marion; Rieckhof, Marvin	2022	Personzentrierte Milieuarbeit: Bindung, Beziehung und Einbettung schaffen für benachteiligte Klienten	Gesprächspsych otherapie und Personzentrierte Beratung	53	1	14-17	Vorgestellt wird das Konzept der personzentrierten Milieuarbeit, eine Form der integrativen personzentrierten Psychotherapie, die sich vor allem an gesellschaftlich benachteiligte Personengruppen richtet.
Galbusera, Laura; Fuchs, Thomas; Holm- Hadulla, Rainer M.; Thoma, Samuel	2022	Person- Centered Psychiatry as Dialogical Psychiatry: The Significance of the Therapeutic Stance	Psychopatholog y	55	1	1-9	In this article, we present holistic and person-centered perspectives in psychiatry, with the aim of better understanding what a focus on personhood might really mean and what clinical implications it might have. We first introduce classical and philosophical concepts of personhood, in order to then outline person-centered approaches in psychiatry, which mainly focus on the person of the patient. We then argue that, for it to really be person-centered, psychiatry must necessarily also focus on the person of professionals. We thus explore the notion of stance, as the expression of the therapist's personhood. By unpacking the effects that a professional's stance can have on patients, we finally turn to a consideration of the interpersonal sphere. More specifically, we propose clinical considerations on a therapeutic stance that strives to support and to help the person of the patient unfold. Such a stance must - we argue - necessarily be a dialogical one. Drawing on these considerations, we thus claim that a truly person-centered approach in psychiatry must necessarily and automatically be interperson-centered and dialogical. In the concluding remarks, we finally discuss broader societal implications and outline future research perspectives.

Galliker, Mark	2020	Die Psychotherapie-Debatte	Gesprächspsychotherapie und Personenzentrierte Beratung	51	3	6-14	<p>Das Werk "Die Psychotherapie-Debatte" von Wampold, Imel und Flockiger bietet einen Überblick der aktuellen Psychotherapieforschung. Fragen werden gestellt wie jene nach der Wirksamkeit von Psychotherapie und jene nach der Effektivität eines bestimmten therapeutischen Verfahrens im Verhältnis zu anderen Verfahren. Dem herkömmlichen Medizinischen Metamodell der Psychotherapieforschung wird das neue Kontextuelle Metamodell der Therapieforschung gegenübergestellt. Die zentrale These der Arbeit lautet, dass zum Nachteil eines wirklichen Verständnisses dessen, wodurch Psychotherapie wirksam wird, mehrere wichtige Aspekte derselben bisher in der Psychotherapieforschung vernachlässigt worden sind. Das umfangreiche Buch sollten m. E. nicht zuletzt GesprächspsychotherapeutInnen zur Kenntnis nehmen, weil es hinsichtlich einer definitiven Anerkennung der Personzentrierten Psychotherapie zu verdeutlichen vermag, welches Potenzial in diesem Verfahren auch aus der Sicht der modernen Therapieforschung steckt. Das Werk besteht aus neun Kapiteln, die im Folgenden zusammengefasst werden. Nach der komprimierten inhaltlichen Darstellung erfolgt eine kurze Diskussion dieser bahnbrechenden Arbeit der Autoren.</p>
Galliker, Mark; Klein, Margot	2018	Auf der Suche nach der verlorenen Zukunft. Ist Rogers' Gesprächspsychotherapie antiquiert oder die	Person	22	1	55-64	<p>Wirksamkeitsprüfungen der Gesprächspsychotherapie nach Rogers in der Psychotherapieforschung werden kritisch diskutiert. Dabei wird betont, dass die sinnvollen Errungenschaften Rogers' zu bewahren nicht "Dogmatismus" bedeutet, sondern die Voraussetzung für die Weiterentwicklung einer humanistischen Psychotherapie ist, die nicht nach Magabe wissenschaftlich fragwürdiger Klassifikationssysteme und Therapieforschungen instrumentell ausgerichtet wird. Es</p>

		Therapieforschung ihr inadquat?					wird postuliert, dass es aufgrund der sogenannten Evidenzbasierten Therapieforschung nicht möglich ist, die Effektivität therapeutischer Verfahren adquat zu evaluieren, diese Verfahren eingehend zu untersuchen oder sie gar zu verbessern, was jedoch im Jubilumsartikel sowie vom Wissenschaftlichen Beirat Psychotherapie ausgeblendet wurde. Im Fokus stehen diagnostische Klassifikationssysteme, Prozess-Analyse, randomisiert-kontrollierte Studien, Meta-Analysen und Therapieforschungsbefunde. Abschließend werden (1) die methodologische Hegemonie des kognitiven Wissenschaftsparadigmas, (2) eine nicht bessere Legitimation der (kognitiven) Verhaltenstherapie als bei anderen therapeutischen Verfahren, (3) das Spannungsfeld zwischen humanistischem Paradigma und kognitiven Perspektiven, (4) die Bedeutung der Prozessanalyse und (5) die Untauglichkeiten von Dogmatismus als auch Revisionismus konstatiert.
Gallin-Anliker, T.; Wiedemann, S.; Bähler, C.; Kaske, M.	2021	Usage of antimicrobials on seven farms of beef producers in Switzerland	Schweizer Archiv für Tierheilkunde	163	12	859–870	It was the objective of this study to evaluate morbidity, mortality, use of veterinary drugs and production output on seven representative Swiss beef fatteners, who bought on a regular basis batches of calves from traders (mean age and weight: 31 day, 75 kg) and practised an all in-all out system. From March 2015 until May 2016, 51 batches with a total of 1307 calves were included. The use of drugs during the first eight weeks following delivery of calves from the trader, casualty rate and carcass performance of 837 bulls. The administration of antimicrobials was calculated per calf as the number of days with effective therapeutic concentrations (daily doses per animal; DD/A). The average weight of the calves at arrival on the fattening unit was 75 kg and the age 31 days. The group size was between 13 to 47 calves

							<p>(median 22, Q1 = 21, Q2 = 30). In 36 batches (70,6 %), a veterinary entry examination was performed which demonstrated that at admission 20 % of the calves suffered from a relevant disease. The median for the number of DD/A was 16 for the first 56 days on the farm (Q1 = 11, Q3 = 21); 68 % of these DD/A were attributed to metaphylactic medications after delivery. Thereafter, pneumonia (54 %), diarrhea (33 %) and otitis (10 %) were the most frequent indications for subsequent therapeutic interventions. Over all batches, a median of 71 % (Q1 = 47, Q3 = 85) of all DD/A were due to critically important antimicrobials (CIM) and drugs containing several antibiotics including a CIM. The losses due to death or euthanasia averaged 3,7 % of all calves. The median for daily weight gain for the total fattening period (median 354 days; Q1 = 328, Q3 = 379) accounted for 1325 g (Q1 = 1216, Q3 = 1425). The profound variation between the farms in respect to the results of drug use and production output reveals evidence for the strong impact of farm-specific factors (such as pen space per calf, barn climate, vaccination protocol, supervision). Concurrently, the remarkable differences between the results of different batches on one farm depict that there are further important risk factors which are beyond the control of the farmer (in particular season of the year, transport). It is concluded that a systematic minimization of risk factors as part of a continuous veterinary consultation is useful to improve herd health and to reduce the input of drugs in the production of beef.</p>
Galvão Gomes da Silva, Joana; Kavanagh, David J.;	2018	Experiences of a Motivational Interview Delivered by a	Journal of medical Internet research	20	5	e116	<p>BACKGROUND: Motivational interviewing is an effective intervention for supporting behavior change but traditionally depends on face-to-face dialogue with a human counselor. This study addressed a key challenge</p>

<p>Belpaeme, Tony; Taylor, Lloyd; Beeson, Konna; Andrade, Jackie</p>		<p>Robot: Qualitative Study</p>				<p>for the goal of developing social robotic motivational interviewers: creating an interview protocol, within the constraints of current artificial intelligence, which participants will find engaging and helpful. OBJECTIVE: The aim of this study was to explore participants' qualitative experiences of a motivational interview delivered by a social robot, including their evaluation of usability of the robot during the interaction and its impact on their motivation. METHODS: NAO robots are humanoid, child-sized social robots. We programmed a NAO robot with Choregraphe software to deliver a scripted motivational interview focused on increasing physical activity. The interview was designed to be comprehensible even without an empathetic response from the robot. Robot breathing and face-tracking functions were used to give an impression of attentiveness. A total of 20 participants took part in the robot-delivered motivational interview and evaluated it after 1 week by responding to a series of written open-ended questions. Each participant was left alone to speak aloud with the robot, advancing through a series of questions by tapping the robot's head sensor. Evaluations were content-analyzed utilizing Boyatzis' steps: (1) sampling and design, (2) developing themes and codes, and (3) validating and applying the codes. RESULTS: Themes focused on interaction with the robot, motivation, change in physical activity, and overall evaluation of the intervention. Participants found the instructions clear and the navigation easy to use. Most enjoyed the interaction but also found it was restricted by the lack of individualized response from the robot. Many positively appraised the nonjudgmental aspect of the interview and how it gave space to articulate their</p>
--	--	---	--	--	--	--

							<p>motivation for change. Some participants felt that the intervention increased their physical activity levels.</p> <p>CONCLUSIONS: Social robots can achieve a fundamental objective of motivational interviewing, encouraging participants to articulate their goals and dilemmas aloud. Because they are perceived as nonjudgmental, robots may have advantages over more humanoid avatars for delivering virtual support for behavioral change.</p>
<p>Ganslev, Christina A.; Storebø, Ole Jakob; Callesen, Henriette E.; Ruddy, Rachel; Søgaard, Ulf</p>	2020	<p>Psychosocial interventions for conversion and dissociative disorders in adults</p>	<p>The Cochrane database of systematic reviews</p>	7	7	<p>CD00533 1</p>	<p>BACKGROUND Conversion and dissociative disorders are conditions where people experience unusual neurological symptoms or changes in awareness or identity. However, symptoms and clinical signs cannot be explained by a neurological disease or other medical condition. Instead, a psychological stressor or trauma is often present. The symptoms are real and can cause significant distress or problems with functioning in everyday life for the people experiencing them.</p> <p>OBJECTIVES To assess the beneficial and harmful effects of psychosocial interventions of conversion and dissociative disorders in adults.</p> <p>SEARCH METHODS We conducted database searches between 16 July and 16 August 2019. We searched Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, and eight other databases, together with reference checking, citation searching and contact with study authors to identify additional studies. SELECTION CRITERIA: We included all randomised controlled trials that compared psychosocial interventions for conversion and dissociative disorders with standard care, wait list or other interventions (pharmaceutical, somatic or</p>

						<p>psychosocial). DATA COLLECTION AND ANALYSIS: We selected, quality assessed and extracted data from the identified studies. Two review authors independently performed all tasks. We used standard Cochrane methodology. For continuous data, we calculated mean differences (MD) and standardised mean differences (SMD) with 95% confidence interval (CI). For dichotomous outcomes, we calculated risk ratio (RR) with 95% CI. We assessed and downgraded the evidence according to the GRADE system for risk of bias, imprecision, indirectness, inconsistency and publication bias.</p> <p>MAIN RESULTS</p> <p>We included 17 studies (16 with parallel-group designs and one with a cross-over design), with 894 participants aged 18 to 80 years (female:male ratio 3:1). The data were separated into 12 comparisons based on the different interventions and comparators. Studies were pooled into the same comparison when identical interventions and comparators were evaluated. The certainty of the evidence was downgraded as a consequence of potential risk of bias, as many of the studies had unclear or inadequate allocation concealment. Further downgrading was performed due to imprecision, few participants and inconsistency. There were 12 comparisons for the primary outcome of reduction in physical signs. Inpatient paradoxical intention therapy compared with outpatient diazepam: inpatient paradoxical intention therapy did not reduce conversive symptoms compared with outpatient diazepam at the end of treatment (RR 1.44, 95% CI 0.91 to 2.28; 1 study, 30 participants; P = 0.12; very low-quality evidence). Inpatient treatment programme plus hypnosis</p>
--	--	--	--	--	--	--

						<p>compared with inpatient treatment programme: inpatient treatment programme plus hypnosis did not reduce severity of impairment compared with inpatient treatment programme at the end of treatment (MD -0.49 (negative value better), 95% CI -1.28 to 0.30; 1 study, 45 participants; P = 0.23; very low-quality evidence).</p> <p>Outpatient hypnosis compared with wait list: outpatient hypnosis might reduce severity of impairment compared with wait list at the end of treatment (MD 2.10 (higher value better), 95% CI 1.34 to 2.86; 1 study, 49 participants; P < 0.00001; low-quality evidence).</p> <p>Behavioural therapy plus routine clinical care compared with routine clinical care: behavioural therapy plus routine clinical care might reduce the number of weekly seizures compared with routine clinical care alone at the end of treatment (MD -21.40 (negative value better), 95% CI -27.88 to -14.92; 1 study, 18 participants; P < 0.00001; very low-quality evidence). Cognitive behavioural therapy (CBT) compared with standard medical care: CBT did not reduce monthly seizure frequency compared to standard medical care at end of treatment (RR 1.56, 95% CI 0.39 to 6.19; 1 study, 16 participants; P = 0.53; very low-quality evidence). CBT did not reduce physical signs compared to standard medical care at the end of treatment (MD -4.75 (negative value better), 95% CI -18.73 to 9.23; 1 study, 61 participants; P = 0.51; low-quality evidence). CBT did not reduce seizure freedom compared to standard medical care at end of treatment (RR 2.33, 95% CI 0.30 to 17.88; 1 trial, 16 participants; P = 0.41; very low-quality evidence).</p> <p>Psychoeducational follow-up programmes compared with treatment as usual (TAU): no study measured reduction in physical signs at end of treatment.</p> <p>Specialised CBT-based physiotherapy inpatient</p>
--	--	--	--	--	--	---

						<p>programme compared with wait list: no study measured reduction in physical signs at end of treatment.</p> <p>Specialised CBT-based physiotherapy outpatient intervention compared with TAU: no study measured reduction in physical signs at end of treatment.</p> <p>Brief psychotherapeutic intervention (psychodynamic interpersonal treatment approach) compared with standard care: brief psychotherapeutic interventions did not reduce conversion symptoms compared to standard care at end of treatment (RR 0.12, 95% CI 0.01 to 2.00; 1 study, 19 participants; P = 0.14; very low-quality evidence).</p> <p>CBT plus adjunctive physical activity (APA) compared with CBT alone: CBT plus APA did not reduce overall physical impacts compared to CBT alone at end of treatment (MD 5.60 (negative value better), 95% CI -15.48 to 26.68; 1 study, 21 participants; P = 0.60; very low-quality evidence).</p> <p>Hypnosis compared to diazepam: hypnosis did not reduce symptoms compared to diazepam at end of treatment (RR 0.69, 95% CI 0.39 to 1.24; 1 study, 40 participants; P = 0.22; very low-quality evidence).</p> <p>Outpatient motivational interviewing (MI) and mindfulness-based psychotherapy compared with psychotherapy alone: psychotherapy preceded by MI might decrease seizure frequency compared with psychotherapy alone at end of treatment (MD 41.40 (negative value better), 95% CI 4.92 to 77.88; 1 study, 54 participants; P = 0.03; very low-quality evidence). The effect on the secondary outcomes was reported in 16/17 studies. None of the studies reported results on adverse effects. In the studies reporting on level of functioning and quality of life at end of treatment the effects ranged from small to no effect.</p> <p>AUTHORS' CONCLUSIONS</p>
--	--	--	--	--	--	---

							The results of the meta-analysis and reporting of single studies suggest there is lack of evidence regarding the effects of any psychosocial intervention on conversion and dissociative disorders in adults. It is not possible to draw any conclusions about potential benefits or harms from the included studies.
Garcia, Danilo; Cloninger, Kevin M.; Cloninger, C. Robert	2023	Coherence of character and temperament drives personality change toward well being in person-centered therapy	Current opinion in psychiatry	36	1	60–66	<p>PURPOSE OF REVIEW: People and communities around the world face many crises, including increasing burdens from disease, psychopathology, burn-out, social distrust, and acts of hate and terrorism. Personality disorder is arguably both a root cause and a consequence of these problems, creating a vicious cycle of suffering caused by fears, immoderate desires, and social distrust that are inconsistent with rational goals and prosocial values. Fortunately, recent advances in understanding the biopsychosocial basis and dynamics of development in personality and its disorders offer insights to address these problems in effective person-centered ways.</p> <p>RECENT FINDINGS: Fundamental advances have been made recently in the understanding of the psychobiology and sociology of personality in relationship to health, and in basic mechanisms of personality change as a complex process of learning and memory. Promotion of self-awareness and intentional self-control releases a strong tendency for people to seek coherence of their emotions and habits with what gives their life meaning and value.</p> <p>SUMMARY: People have a strong drive to cultivate personalities in which their emotions and habits are reliably in accord with reasonable goals and prosocial values. Person-centered therapeutics provide practical ways to promote a virtuous cycle of increasing well being for individuals and their communities and habitats.</p>

García, Enara; Di Paolo, Ezequiel A.; Jaegher, Hanne de	2022	Embodiment in online psychotherapy: A qualitative study	Psychology and psychotherapy	95	1	191–211	<p>UNLABELLED</p> <p>As a result of the COVID-19 pandemic, many therapists and patients have been required to switch to online sessions in order to continue their treatments. Online psychotherapy has become increasingly popular, and although its efficacy seems to be similar to face-to-face encounters, its capacity to support the implicit nonverbal and embodied aspects of the therapeutic relationship has been questioned and remains understudied.</p> <p>OBJECTIVES</p> <p>To study how embodied and intersubjective processes are modified in online psychotherapy sessions.</p> <p>DESIGN</p> <p>Taking the enactive concept of participatory sense-making as a guiding thread, we designed an interpretative phenomenological analysis to examine the experiences of embodiment in online therapy.</p> <p>METHODS</p> <p>We conducted phenomenological semi-structured interviews with patients and therapists who have recently switched from face-to-face encounters to online modality.</p> <p>RESULTS</p> <p>Adjustments in verbal and nonverbal behavior, gaze behavior, management of silences, and displacements of non-intentional and pre-reflective patterns onto reflective ones are reported as necessary to compensate for changes introduced in the online modality.</p> <p>CONCLUSIONS</p> <p>From an enactive perspective, such adaptations manifest regulatory processes aimed at sustaining interactive dynamics and coordinating the primordial tension between relational and individual norms in social</p>
---	------	---	---------------------------------	----	---	---------	--

						<p>encounters.</p> <p>PRACTITIONER POINTS</p> <p>We examine different aspects of embodiment that practitioners should take into account when switching from face-to-face to online encounters with their clients. Online communication systems can alter aspects of the therapeutic relationship, such as its structure, its fragility, and its significance. Video calls afford new forms of intervention such as integrating the experience of patients with their self-image, incorporating information about their habitual environment into the process, and adopting less confrontational therapeutic styles.</p>	
Garcia, Hector A.; Mignogna, Joseph; DeBeer, Bryann R.; Song, Jiyoung; Haro, Elizabeth K.; Finley, Erin P.	2020	Provider factors predict use of evidence-based psychotherapies in veterans affairs posttraumatic stress disorder specialty programs: The role of profession, theoretical orientation, and training	Traumatology	26	2	227-234	<p>Although a large body of research indicates that evidence-based psychotherapies for posttraumatic stress disorder (PTSD) such as prolonged exposure (PE) and cognitive processing therapy (CPT) are both effective and efficacious in veteran populations, less is known about provider factors that impact decisions to utilize these treatments. The current study aims (a) to describe use of CPT, PE, and “other” psychotherapies among Veterans Health Administration (VHA) PTSD specialty care providers, and (b) to examine whether factors such as theoretical orientation, occupation, graduate training in cognitive-behavioral therapy, and having received VHA training are associated with providers’ use of specific PTSD treatments. VHA providers in PTSD clinical teams were invited to participate in a national survey (n = 259, response rate = 24.2%) assessing provider demographics, treatment preferences, and treatment use. Overall, providers reported using CPT and PE for PTSD for a relatively low percentage of their clinical time (mean of 38.8% for CPT and 19.8% for PE), relying more heavily on use of “other” psychotherapies (mean of 44.8%) in patient</p>

							care. VHA evidence-based psychotherapy training emerged as a predictor of time spent administering CPT or PE. Having a cognitive-behavioral therapy theoretical orientation was associated with time spent conducting CPT, but not PE, whereas identification with “other” orientation was associated with time spent conducting psychotherapies other than CPT or PE. García-Mieres, Helena; Niño-Robles, Noelia; Ochoa, Susana; Feixas, Guillem	2019	Exploring identity and personal meanings in psychosis using the repertory grid technique: A systematic review	Clinical psychology & psychotherapy	26	6	717-733	Current research and clinical practice in person-centred approaches highlight the importance of self, identity, and personal meanings in psychosis. Previous research has focused on dimensions of self, but less attention has been paid to the personal meanings involved in identity. The personal construct theory framework and the repertory grid technique (RGT) allow the study of identity and personal meanings within person-centred approaches of psychopathology and treatment in psychosis, as suggested by studies that began more than 40 years ago. However, their contributions have not yet been reviewed. We aimed to systematically review the evidence for the role of identity and personal meanings in psychotic disorders. We performed a systematic search using personal construct and RGT terms in PsycINFO, Web of Science, PubMed, EBSCO, Scopus, and Google Scholar. After identifying 2,574 articles, 15 were included. Nine studies followed an idiographic assessment, and six were nomothetic. Patients reported their subjective experience of isolation in terms of high self-ideal discrepancy and high perceived discrepancy with their significant others, which some studies associated with a lower degree of recovery or with the way in which positive symptoms were construed. Self-fragmentation either decreased with interventions or was associated with

							recovery. Evidence regarding interpersonal construing was less consistent, but there was a tendency for patients to show a more rigid cognitive structure than controls. To conclude, we found some evidence that self-discrepancies, fragmentation of self, and interpersonal construing are affected in psychosis and potentially modifiable through psychotherapy.
García-Soler, Álvaro; Díaz-Veiga, Pura; Suárez Pérez de Eulate, Nerea; Mondragón, Gabriela; Sancho, Mayte	2017	Study of engagement in a group of people with dementia in traditional care settings and a group with person centred care	Revista española de geriatría y gerontología	52	2	65–70	INTRODUCTION: People with dementia in the residential care setting have a high level of apathy and disengagement. The lack of stimulation and customised activities, a common aspect in residential centres, could be contextual elements that promote these behaviours. The person-centred care model (PCCM) promotes the participation of people in their daily activities in relation to their resources, interests, and needs. The aim of this study is to compare the frequency of engagement behaviours in the daily activities in two groups of users residing in Psychogeriatric Units, one receiving a traditional care model and the other assisted under PCCM. METHODOLOGY: The study involved 28 patients with cognitive impairment in Psychogeriatric Units, 14 of whom were in a traditional unit (control group), and 14 were in a unit where PCCM (experimental group) was implemented. Groups were equivalent in cognitive impairment, functional capabilities, and years in the long-term care institution. The Registering Engagement Instrument (REI) was used to observe the frequency of 12 categories of engagement behaviour in two distinct periods in both groups: before the interventions associated with PCCM, and 18 months after starting them. RESULTS: Both groups increased the frequency of their engagement behaviours in the post-evaluation, but the experimental group decreased their disengagement

							behaviours while the control group increased them. CONCLUSIONS: According to the data, PCCM interventions could reduce disengagement behaviours in the residential context, and could facilitate the participation and involvement in the activities of daily living.
Gardner, Kathryn Jane; Wright, Karen M.; Elliott, Alison; Graham, Simon; Fonagy, Peter	2020	The weirdness of having a bunch of other minds like yours in the room: The lived experiences of mentalization-based therapy for borderline personality disorder	Psychology and psychotherapy	93	3	572–586	Objectives Studies of lived experiences are important for improving treatment effectiveness, but most studies of mentalization-based therapy (MBT) are quantitative. This qualitative study aimed to better understand service users' lived experiences of MBT, including their experiences of change. Design This is a qualitative study that used one-to-one semi-structured interviews. Method Semi-structured interviews were conducted with eight MBT service users recruited via four NHS trusts. Interviews were analysed using interpretative phenomenological analysis (IPA). Findings Three superordinate themes were identified: being borderline, being in the group, and being on a journey. Experiences of diagnosis and the group are salient topics in the lived experiences of service users during the MBT journey, as is the nature/type of change that can create symptom reduction albeit alongside a negative felt experience. Conclusion Our research aligns with current thought regarding the complexity and challenges of treating BPD via psychotherapy and adds a further dimension, that of experiencing MBT and changes during therapy. The participants' experiences of BPD and of experiencing MBT are discussed. Practitioner points Therapists are observant of how each client gives meaning to their experience of diagnosis, the group, and change, particularly since the experience of recovery is not all positive. Service users' emerging and ongoing

							construction of their experience of diagnosis is closely monitored and additional appropriate strategies implemented where necessary. The impact of joining MBT, especially the group, becomes a process for formal regular review. Therapists undertake an in-depth exploration of service users' felt experiences to capture less quantifiable dimensions of change.
Garland, Sheila N.; Trevino, Kelly; Liou, Kevin T.; Gehrman, Philip; Spiguel, Eugenie; MacLeod, Jodi; Walker, Desirée A. H.; Glosik, Betsy; Seluzicki, Christina; Barg, Frances K.; Mao, Jun J.	2021	Multi-stakeholder perspectives on managing insomnia in cancer survivors: recommendations to reduce barriers and translate patient-centered research into practice	Journal of cancer survivorship : research and practice	15	6	951–960	<p>PURPOSE: Insomnia is a debilitating symptom experienced by nearly 60% of cancer survivors. Building on our prior research showing the clinical benefit of cognitive behavioral therapy for insomnia (CBT-I) and acupuncture, we organized a workshop of patient advocates and clinician stakeholders to understand the barriers and develop recommendations for the dissemination and implementation of these interventions. METHODS: Participants completed a pre-workshop survey assessing their experiences with insomnia and barriers to insomnia treatment and participated in a workshop facilitated by professionals and patient experts. Responses from the survey were tabulated and the discussions from the workshop were content-analyzed to extract relevant factors that may influence dissemination and implementation. RESULTS: Multidisciplinary and stakeholder workshop participants (N = 51) identified barriers and proposed solutions and future recommendations for dissemination and implementation of evidence-based interventions to improve sleep health in cancer survivors. Barriers were identified in four categories: patient (e.g., knowledge, time, cost), clinician (e.g., education, time, capacity), institutional (e.g., space, insurance reimbursement, referrals), and societal (e.g., lack of prioritization for sleep issues). Based on these categories, we made six</p>

							<p>recommendations for dissemination and implementation of research findings to improve clinical sleep management in oncology. CONCLUSION: Dissemination and implementation efforts are necessary to translate research into clinical practice to improve patient care. IMPLICATIONS FOR CANCER SURVIVORS: Sleep needs to be prioritized in cancer care, but patient, provider, and institutional/societal barriers remain. Dedicated effort and resources at each of these levels are needed to help millions of people affected by cancer manage their insomnia and improve their quality of life.</p>
Garrido-Fernández, Miguel; Marcos-Sierra, Juan A.; López-Jiménez, Ana; Ochoa de Alda, Iñigo	2017	Multi-Family Therapy with a Reflecting Team: A Preliminary Study on Efficacy among Opiate Addicts in Methadone Maintenance Treatment	Journal of marital and family therapy	43	2	338–351	<p>In this study, we evaluate the efficacy of multi-family therapy at reducing the addiction severity and at improving the psychological and family dynamics of opiate addicts receiving methadone treatment at a public treatment center. The study compares multi-family therapy with a reflecting team (MFT-RT) and a standard treatment following a methadone maintenance treatment program. The results show that multi-family therapy with a reflecting team effectively reduces the addiction severity in several of the areas evaluated and noted that this effect is superior to standard treatment. The psychotherapy patients showed improvement in the areas of employment and social support; their drug use diminished and their psychiatric condition improved. At the same time, they needed a lower daily dose of methadone. In addition, the group undergoing standard treatment showed a noteworthy deterioration in their medical condition. Both groups showed a significant increase in their alcohol use. When applied to family treatments, the systemic-constructivist approach by the reflecting team offers combined techniques that can help</p>

							improve care for the families of patients with addiction problems.
Garrote-Caparrós, Elena; Lecuona, Óscar; Bellosta-Batalla, Miguel; Moya-Albiol, Luis; Cebolla, Ausiàs	2023	Efficacy of a mindfulness and compassion-based intervention in psychotherapists and their patients: Empathy, symptomatology, and mechanisms of change in a randomized controlled trial	Psychotherapy		19-39-1536(Electronic), 0033-3204(Print)	182-193	In recent years, mindfulness and compassion-based interventions (MCBI) have been found to beneficially influence the acquisition of essential skills in psychotherapy and are a promising way to improve relationships with patients. In this regard, new studies are needed to evaluate the effects of MCBI on psychotherapists and their patients and to analyze the influence of these effects on the processes and outcomes of psychotherapy. In this randomized controlled trial, we evaluate the efficacy of an MCBI in psychotherapists' mindfulness skills and self-reported empathy, as well as its indirect effect on patients (patient-reported psychotherapists' empathy, therapeutic bond, and symptomatology). Finally, we present a multilevel structural equation model (MSEM) to analyze the relationship between these variables in psychotherapists and their patients. A group of psychotherapists (N = 63) were randomized to an MCBI or an active control group (empathy diary). We assessed psychotherapists and their patients (N = 121) before and after the MCBI and at follow-up evaluation. Psychotherapists' results showed an increase in psychotherapeutic mindfulness skills (PMS) after the MCBI and at follow-up, whereas self-reported empathy improved at follow-up. Patients' results showed an improvement in perceived empathy, therapeutic bond, and symptomatology after the MCBI. The improvements in symptomatology were maintained for somatization and anxiety at follow-up. According to the MSEM, the increase in PMS is related to an increase in patient-reported psychotherapists' empathy, which produces an improvement in therapeutic bond and their

							symptomatology. These results support the benefits of introducing MCBI in psychotherapists' training to improve the psychotherapy outcomes. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Gaume, Jacques; Hallgren, Kevin A.; Clair, Carole; Schmid Mast, Marianne; Carrard, Valérie; Atkins, David C.	2019	Modeling empathy as synchrony in clinician and patient vocally encoded emotional arousal: A failure to replicate	Journal of Counseling Psychology		19 39- 21 68(Ele ctr oni c), 00 22- 01 67(Pri nt)	341-350	Empathy is a well-defined active ingredient in clinical encounters. To measure empathy, the current gold standard is behavioral coding (i.e., trained coders attribute overall ratings of empathy to clinician behaviors within an encounter), which is labor intensive and subject to important reliability challenges. Recently, an alternative measurement has been proposed: capturing empathy as synchrony in vocally encoded arousal, which can be measured as the mean fundamental frequency of the voice (mean F0). This method has received preliminary support by one study (Imel, Barco, et al., 2014). We aimed to replicate this study by using 2 large samples of clinical interactions (alcohol brief motivational interventions with young adults, N = 208; general practice consultations, N = 204). Audio files were segmented to identify respective speakers and mean F0 was measured using speech signal processing software. All sessions were independently rated by behavioral coders using 2 validated empathy scales. Synchrony between clinician and patient F0 was analyzed using multivariate multilevel models and compared with high and low levels of empathy derived from behavioral coding. Findings showed no support for our hypothesis that mean F0 synchrony between clinicians and patients would be higher in high-empathy sessions. This lack of replication was consistent for both clinical samples, both behavioral coding instruments, and using measures of F0 synchrony occurring at both the session-level and minute-level. We considered differences in culture and

							language, patients' characteristics, and setting as explanations for this failure to replicate. Further replication testing and new developments regarding measurement methods and modeling are needed. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Gaume, Jacques; Magill, Molly; Gmel, Gerhard; Daeppen, Jean-Bernard	2021	Motivational interviewing technical and relational skills, change talk, and alcohol outcomes - A moderated mediation analysis	Journal of consulting and clinical psychology	89	8	707-716	Objective: Change talk has been proposed as a mechanism of change in motivational interviewing (MI) by mediating the link between MI technical skills and behavioral outcomes. We tested the influence of therapists' relational skills on this mediation model. Method: Secondary analysis of a randomized controlled trial of individual brief MI for heavy drinking among 20-year-old-Swiss young men, where the MI group (n = 179) significantly reduced drinking compared to an assessment-only control. We coded MI sessions and derived: therapists' MI technical skills, clients' change talk (CT) and sustain talk (ST), and global relational ratings (empathy and MI spirit). We tested moderated mediation models with technical skills as the independent variable, CT and ST as parallel mediators, predicting drinking at 3-month follow-up (controlling for baseline drinking), and relational skills as moderators of the path from technical skills to client mediators. Results: Conditional indirect effects were significant for overall MI technical skills, open questions, and simple reflections (i.e., more of these behaviors related to more ST, which was related to more drinking) when relational skills were low. In contrast, there was a significant conditional indirect effect for complex reflections when relational skills were high (i.e., more complex reflections related to less ST). Conclusions: This study provides partial support for the MI technical and relational process models. Interestingly,

							support was found regarding the negative side of client ambivalence (ST) in this highly precontemplative sample. Accordingly, MI therapists should work cautiously with ST when clients are at early stages of motivational readiness.
Gawlik, A.; Lüdemann, J.; Neuhausen, A.; Zepp, C.; Vitinius, F.; Kleinert, J.	2023	A Systematic Review of Workplace Physical Activity Coaching	Journal of occupational rehabilitation	33	3	550–569	<p>Aim Studies show that about 60 min of moderate physical activity (PA) per day compensate for sitting all day at work. However, the workplace offers an ideal setting for health-promoting interventions such as PA coaching as a person-centered intervention aimed at achieving lasting health behavior changes. Given a good evidence base of health coaching studies in general, this systematic review aims to provide an overview of workplace PA coaching interventions. Methods This review was conducted according to PRISMA guidelines. Studies published up to July 2021 were considered based on the following inclusion criteria: (1) longitudinal intervention studies, (2) analysis of PA at work, (3) sedentary employees, (4) PA coaching in the workplace as intervention, (5) increasing workplace PA. Results Of 4323 studies found, 14 studies with 17 interventions met inclusion criteria. All 17 interventions indicated an increase in at least one PA outcome. Twelve interventions indicated significant improvements in at least one workplace or total PA outcome. There is a high variation within the different coaching parameters, such as behavior change techniques and communication channels. The study quality showed a moderate to high risk of bias. Conclusions The majority of interventions provided evidence for the effectiveness of workplace PA coaching. Nevertheless, the results are inconclusive with regard to the variety of coaching parameters and thus no general statement can be made about the effectiveness of individual parameters. However, this variety of</p>

							parameters also leads to a high degree of individualization of workplace PA coaching interventions to increase PA for different groups of employees and different types of workplaces.
Gdde, Gnter	2016	Die Weichenstellung zur therapeutischen Beziehung als vorrangigem Therapiefokus					Aus historischer Perspektive wird der Frage nachgegangen, wie es dazu gekommen ist, dass die therapeutische Beziehung in den psychodynamischen Therapien zum zentralen Therapiefokus geworden ist. Den Ausgangspunkt bildet Freuds Theoriekonzeption, die an die Erfahrungen der Hypnotiseure mit dem "Rapport", einer Vorform der Übertragung, anknüpfte und eine radikale Umkehrung des Arzt-Patient-Verhältnisses mit sich brachte, da der Patient das Recht erhielt, in freier Themenwahl sein Leiden selbst darzustellen. In den 1920er-Jahren kam es zu einer bis heute nachwirkenden Debatte mit S. Ferenczi, in der sich die Polarisierung von "Einsichts-" und "Erlebnistherapie" herauskristallisierte. Während die Einsichtstherapie, geprägt von den Annahmen der psychoanalytischen Ich- und Triebpsychologie, an einem intrapsychischen Paradigma orientiert blieb, gingen Objektbeziehungspsychologen - etwa M. Balint und D. W. Winnicott - im Rahmen einer Therapie der emotionalen Erfahrung zu einem "Beziehungsparadigma" über, in dem Übertragung und Gegenübertragung interaktionell und zirkulär gesehen wurden und der Anteil des Therapeuten und damit die aktualgenetische Übertragungs-Gegenübertragungsdynamik im Hier und Jetzt zunehmend mehr Berücksichtigung fanden. Die weitere Entwicklung der psychodynamischen Psychotherapie führte zu einer stärkeren Beachtung der Empathie des Therapeuten und der Subtilität und Wechselseitigkeit in den therapeutischen Interaktionen ("intersubjektives Paradigma").

Geiser, Christiane	2021	Verkrperte Trume	Psychotherapie-Wissenschaft	11	2	47-54	Vorgestellt wird der Umgang mit Trumen in einer personenzentriert-experienziellen Krperpsychotherapie, wie sie im Ausbildungsinstitut GFK in Zrich vermittelt wird. Nach einfhrenden therapietheoretischen berlegungen wird anhand einer ausfhrlichen, kommentierten Falldarstellung gezeigt, wie der Therapieverlauf unter Einbeziehung des Traumerlebens konsequent immer wieder zum Bezugsrahmen der Klientin zurckkehrt und ihre innere Bewegung in Bezug auf ihr eigenes Erleben untersttzt. Dabei werden unterschiedliche Modalitten angefragt und ausgefaltet, die der Klientin mglich sind und die den Prozess fortfhren. Die Therapeutin ist in der Beziehung als Person mit ihren eigenen Erlebensresonanzen prsent.
Gelfand, Samantha L.; Scherer, Jennifer S.; Koncicki, Holly M.	2020	Kidney Supportive Care: Core Curriculum 2020	American journal of kidney diseases : the official journal of the National Kidney Foundation	75	5	793-806	Kidney supportive care is the application of palliative medicine principles and practices to patients with kidney disease. The goal is alleviation of suffering through treatment of symptoms, empathic communication, and support for psychosocial distress. Kidney supportive care includes primary palliative care provided by nephrology teams, as well as referral of patients with complex distress for comanagement by an interprofessional specialty palliative care team, when available. The team may include physicians, nurses, social workers, chaplains, and dieticians. Comanagement with nephrologists offers an additional layer of support to patients and families as prognostic awareness, patient preferences, and care decisions are explored. Kidney supportive care can be offered to patients experiencing acute kidney injury or chronic kidney disease, including those with kidney failure treated by kidney replacement therapy (dialysis and transplantation). Kidney supportive care includes but is not limited to end-of-life care. This

							installment of the Core Curriculum in Nephrology outlines several practical applications of kidney supportive care, with a focus on the nephrologist's approach to symptom management, active medical management of kidney failure without dialysis (also known as comprehensive conservative care), acute kidney injury in seriously ill patients, and withdrawal from dialysis.
Gelso, Charles J.; Kivlighan Jr., Dennis M.; Markin, Rayna D.	2018	The real relationship and its role in psychotherapy outcome: A meta-analysis	Psychotherapy	55	4	434–444	Although writing about the real relationship has existed from the beginnings of the “talking cure,” it is only in recent years that empirical research has focused on this phenomenon. The real relationship is the personal relationship between patient and therapist marked by the extent to which each is genuine with the other and perceives/experiences the other in ways that are realistic. The strength of the real relationship is determined by both the extent to which it exists and the degree to which it is positive or favorable. In this article, a meta-analysis is presented on the association between the strength of the real relationship and the outcome of psychotherapy. Summed across 16 studies, this meta-analysis revealed a moderate association with outcome ($r = .38$, 95% confidence interval $ [.30, .44]$, $p < .001$, $d = 0.80$, $N = 1.502$). This real relationship–outcome association was independent of the type of outcome studied (treatment outcome, treatment progress, and session outcome) and of the source of the measure (whether the client or the therapist rated the real relationship and/or treatment outcome). We also present commonly used measures of the real relationship, limitations of the research, and patient contributions. The article concludes with diversity considerations and practice recommendations for developing and strengthening the real relationship.

Genova, Federica; Zingaretti, Pietro; Gazzillo, Francesco; Tanzilli, Annalisa; Lingiardi, Vittorio; Katz, Michael; Hilsenroth, Mark	2021	Patients' crying experiences in psychotherapy and relationship with working alliance, therapeutic change and attachment styles	Psychotherapy	58	1	160-171	Crying may be a beneficial experience and reflect a patients' involvement in the therapeutic work, as well as a potential indicator of the healing process. This study explored the relationships between patients' crying experience in therapy, their perception of working alliance and therapeutic change, as well as considering the role of attachment styles. One hundred six patients completed a survey about crying in psychotherapy and self-report measures for assessing working alliance, therapeutic change, and attachment styles. Concerning general crying experiences, results showed that when patients' crying (even if painful) was followed by more positive or less negative emotions (i.e., a sense of relief), they perceived the working alliance more positively and therapeutic change as enhanced. Similarly, regarding their most recent crying episode, patients' feeling of crying as a positive (albeit often painful) experience was related with a better perception of working alliance and therapeutic change. In relation to variance explained by patient attachment style, our results are quite limited and secondary to the findings on crying-related experiences, working alliance and therapeutic change. However, when attachment style did contribute significantly to a regression model, results indicated that for patients with high dismissing attachment concerns, crying in a context of a good working alliance may represent both a useful process for reducing negative emotions and an indicator of good therapeutic outcome. Clinical and empirical implications are discussed in terms of the relevance of the therapeutic crying experience on the quality of

							working alliance and therapeutic change. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Gentles, Stephen J.; Nicholas, David B.; Jack, Susan M.; McKibbon, K. Ann; Szatmari, Peter	2018	Parent engagement in autism-related care: a qualitative grounded theory study	Health psychology and behavioral medicine	7	1	1-18	Parents of children with autism assume substantial responsibility for navigating intervention to address autism-related concerns, including involvement in therapy. Little is known, from the perspective of these parents, regarding how to best engage and support them in this navigating process as it evolves over the child's development. In this article, we present findings from a large qualitative study that investigated how parents of children with autism navigate intervention, to construct an in-depth theoretical account of how this group comes to be engaged in individual-level care. Using grounded theory methods and a symbolic interactionist framework, we analyzed select documents and 45 intensive interviews conducted with 32 mothers and 9 expert professionals from urban and rural regions of Ontario, Canada. Parent-defined concerns are the central impetus for the core process of navigating intervention, labeled using parents' language making your own way. We describe how this process is analogous to engaging in care. Four meaning-making processes - defining concerns, informing the self, seeing what is involved, and adapting emotionally - all interacting in an ongoing fashion, together account for parents' evolving readiness and motivation for taking action to navigate intervention. We illustrate how parents' readiness and motivation for navigating intervention (and thus for engagement) evolves over a generalized trajectory, according to three highly overlapping processes experienced by most parents: coming to understand their child has autism, going into high gear, and easing off. These findings indicate multiple empirical conditions and factors affecting engagement

							that service planners and professionals will likely want to consider when seeking parent involvement as a means to improve outcomes in autism. Additionally, theoretical aspects are relevant to the developing understanding of how healthcare consumers in general become engaged in individual care, with implications for patient-centered care.
Gericke, Franco; Ebert, David D.; Breet, Elsie; Auerbach, Randy P.; Bantjes, Jason	2021	A qualitative study of university students' experience of Internet-based CBT for depression	Couns and Psychother Res (Counselling and Psychotherapy Research)	21	4	792–804	
Germer, Sylvan; Weyrich, Vanessa; Bräscher, Anne-Kathrin; Mütze, Kaline; Witthöft, Michael	2022	Does practice really make perfect? A longitudinal analysis of the relationship between therapist experience and therapy outcome: A replication of Goldberg, Rousmaniere, et al. (2016)	Journal of Counseling Psychology		19 39- 21 68(Ele ctr oni c), 00 22- 01 67(Pri nt)	745–754	Experience is often regarded as a prerequisite of high performance. In the field of psychotherapy, research has yielded inconsistent results regarding the association between experience and therapy outcome. However, this research was mostly conducted cross-sectionally. A longitudinal study from the U.S. recently indicated that psychotherapists' experience was not associated with therapy outcomes. The present study aimed at replicating Goldberg, Rousmaniere, et al. (2016) study in the German healthcare system. Using routine evaluation data of a large German university psychotherapy outpatient clinic, the effect of N = 241 therapists' experience on the outcomes of their patients (N = 3,432) was assessed longitudinally using linear and logistic multilevel modeling. Experience was operationalized using the number of days since the first patient of a therapist as well as using the number of patients treated beforehand. Outcome criteria were defined as change in general

							psychopathology as well as response, remission, and early termination. Several covariates (number of sessions per case, licensure, and main diagnosis) were also examined. Across all operationalizations of experience (time since first patient and number of cases treated) and therapy outcome (change in psychopathology, response, remission, and early termination), results largely suggest no association between therapists' experience and therapy outcome. Preliminary evidence suggests that therapists need fewer sessions to achieve the same outcomes when they gain more experience. Therapeutic experience seems to be unrelated to patients' change in psychopathology. This lack of findings is of importance for improving postgraduate training and the quality of psychotherapy in general. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Germing, Cathrin	2018	Qualitätssicherung in Weiterbildungs-einrichtungen: Diskussion eines populären Phänomens	Gesprächspsychotherapie und Personenzentrierte Beratung	49	4	200–203	Aus Sicht einer Gutachterin wird über das Qualitätsmanagement in der Aus- und Weiterbildung im Allgemeinen und in der personenzentrierten Beratung bzw. Beratungsausbildung im Speziellen reflektiert. Zunächst werden Bedeutung und Entwicklung von qualitätssichernden Maßnahmen wie Gütesiegeln im Bildungsbereich dargestellt. Kernaspekte bilden demnach Prozesstransparenz sowie die kontinuierliche Verbesserung des Systems mit dem Ziel einer Standardisierung. Thematisiert wird darüber die Perspektive der Kunden und der zu zertifizierenden Einrichtung. Abschließend werden Anregungen zum Qualitätsmanagement auf individueller und institutioneller Ebene in Bezug auf die personenzentrierte Arbeit formuliert.
Ghafoori, Bitia; Garfin, Dana	2019	Predictors of treatment	Psychological trauma : theory,	11	7	767–774	OBJECTIVE: Few studies have investigated determinants of trauma-informed care (TIC) in vulnerable youth

Rose; Ramírez, Jesse; Khoo, Su Fern		initiation, completion, and selection among youth offered trauma-informed care	research, practice and policy				<p>populations. The purpose of the present study was to investigate factors associated with initiation, completion, and selection of type of TIC treatment among a sample of 128 treatment-seeking youth who experienced crime or violence. METHOD: This retrospective medical record review study used data collected through routine clinical care at an outpatient, no-cost community mental health clinic. RESULTS: We found that 69.5% of treatment-seeking youth (n = 89) initiated treatment, defined as attending at least 1 TIC session. Among youth who initiated treatment, 61.8% (n = 55) completed a TIC treatment. Predisposing and need characteristics were not significantly associated with initiating or completing treatment in adjusted models. Youth assigned to trauma-focused cognitive-behavioral therapy (TF-CBT) were more likely to complete treatment compared with those assigned to child-centered therapy (CCT) approaches (odds ratio [OR] = 4.48, 95% CI [1.35, 14.91], p = .014). Logistic regression analyses suggested therapists were less likely to select TF-CBT for children with higher externalizing symptoms (OR = 0.92, 95% CI [0.85, 0.99], p = .035). CONCLUSIONS: Findings suggest among youth who called in for treatment, many successfully initiated treatment, and of those who initiated, most completed treatment. Empirically supported treatments such as TF-CBT may further promote treatment completion. (PsycINFO Database Record (c) 2019 APA, all rights reserved).</p>
Ghafoori, Bitia; Hansen, Marissa C.; Garibay, Erika;	2017	Feasibility of Training Frontline Therapists in Prolonged	The Journal of nervous and mental disease	205	4	283–293	<p>The study aims were to determine whether prolonged exposure (PE) improved mental health and was feasible to implement by frontline clinicians in a culturally diverse sample with complex trauma. Seventy-one individuals were randomly assigned to PE or person-centered therapy</p>

Korosteleva, Olga		Exposure: A Randomized Controlled Pilot Study of Treatment of Complex Trauma in Diverse Victims of Crime and Violence					(PCT). Outcome measures were administered at baseline and sessions 3, 6, 9, and 12. Mixed modeling was used to regress outcome measures on time, treatment group, and number of visits. Individuals who received PE showed significant moderate association with decline in reported posttraumatic stress disorder (PTSD) symptoms as noted by the PTSD Checklist for DSM-5 ($p = 0.05$) compared with PCT. Results indicated improved scores on all measures at each follow-up time point compared with baseline ($p \leq 0.01$). PE was feasible, shown by positive recruitment and ability of clinicians to effectively implement and maintain treatment fidelity. Findings suggest that PE can be effective for treating complex trauma when used by clinicians in community settings.
Ghafoori, Bitia; Matos, Marlene; Gonçalves, Mariana	2022	Dropout from evidence-based trauma treatment in a community mental health clinic serving victims of interpersonal violence	J. Traum. Stress (Journal of Traumatic Stress)	35	3	1025–1041	Trauma-focused psychotherapies are increasingly offered in community-based mental health centers, but little is known about treatment dropout in these settings. The current study explored dropout at different stages of treatment in a treatment-seeking sample of 1,186 adults who experienced interpersonal violence and were offered trauma-focused and non-trauma-focused therapies. A total of 31.6% of participants dropped out before treatment initiation, 28.0% dropped out after treatment initiation and completed a mean of 4.02 (SD = 2.41) sessions, and 40.4% completed a full course of PTSD treatment. Being unemployed, $p < .001$, and scoring lower on measures of environment factors, $p = .045$, were significant predictors of pretreatment dropout. Being female, $p < .001$; Latinx, $p = .032$; and scoring higher on a measure of social relationships, $p = .024$, were independent predictors of postinitiation dropout. Individuals who completed nine sessions of treatment displayed significantly lower levels of posttraumatic

							stress disorder, depression, and anxiety symptoms. The present study provides preliminary evidence that survivors of interpersonal violence who seek therapy tend to drop out early during treatment, and most who complete treatment attain symptom reduction.
Ghafoori, Bitia; Wolf, Melissa Gordon; Nylund-Gibson, Karen; Felix, Erika D.	2019	A naturalistic study exploring mental health outcomes following trauma-focused treatment among diverse survivors of crime and violence	Journal of affective disorders	245		617–625	<p>BACKGROUND: Although considerable research has tested evidence-based practices in clinical trials, research is needed on the use of trauma-focused treatments by victims of crime and violence in naturalistic settings. This study investigated four trauma-focused treatments, prolonged exposure therapy (PE), cognitive behavioral therapy (CBT), eclectic therapy, and person-centered therapy (PCT), and assessed treatment dropout and symptom improvement over five assessment time-points. METHODS: Descriptive comparisons and pattern mixture multigroup growth models were used to assess differences between treatments on time in treatment, rate of dropout, and improvement in posttraumatic stress (PTSD) and depression symptoms in an outpatient sample of 526 clients seeking routine clinical care. RESULTS: PCT was significantly associated with the highest number of therapy sessions completed and the lowest rate of dropout (41.75%) compared to CBT and eclectic treatments. All treatment groups reported PTSD symptom improvement with no significant differences based on therapy type. For depression, the rate of improvement for clients in PCT who dropped out of treatment after session 3 was significantly steeper than the rate of improvement for clients in eclectic treatment who dropped out of treatment after session 3. Clients who stayed in treatment longer generally had larger decreases in symptoms compared to those who dropped out earlier. LIMITATIONS: The small sample size in each of</p>

							the treatment groups may have limited power to detect change. CONCLUSIONS: Several trauma-focused treatments offered in a community-based setting may result in significant symptomatic improvement.
Ghai, Shashank; Ghai, Ishan; Narciss, Susanne	2022	Auditory stimulation improves gait and posture in cerebral palsy: A systematic review with between- and within-group meta-analysis	Children, 2022				The past decade has seen an increased interest in the implementation of auditory stimulation (AStim) for managing gait and postural deficits in people with cerebral palsy. Although existing reviews report beneficial effects of AStim on the spatiotemporal and kinematic parameters of gait, there are still numerous limitations that need to be addressed to correctly interpret these results. For instance, existing reviews have failed to characterize the effects of AStim by conducting separate between and within-group meta-analyses, these reviews have not evaluated the influence of AStim on postural outcomes, and nor have included several high-quality existing trials. In this study, we conducted between- and within-group meta-analyses to establish a state of evidence for the influence of AStim on gait and postural outcomes in people with cerebral palsy. We searched the literature according to PRISMA-P guidelines across 10 databases. Of 1414 records, 14 studies, including a total of 325 people with cerebral palsy, met the inclusion criterion. We report a significant enhancement in gait speed, stride length, cadence, and gross motor function (standing and walking) outcomes with AStim compared to conventional physiotherapy. The findings from this analysis reveal the beneficial influence of AStim on the spatiotemporal and kinematic parameters of gait and postural stability in people with cerebral palsy. Furthermore, we discuss the futurized implementation of smart wearables that can deliver person-centred AStim rehabilitation in people with cerebral palsy.

Ghanaati, Zahra	2021	Die Bedeutung der interkulturellen Öffnung in der Personzentrierten Supervision	Gesprächspsychotherapie und Personzentrierte Beratung	52	4	6-11	Aufgrund meiner iranischen Wurzeln habe ich lernen müssen, mein eigenes Kulturbewusstsein zu erweitern, indem ich mich mit und gegenüber anderen Kulturen öffne. Im Laufe der GwG-Weiterbildung zur Personzentrierten Supervisorin wurde mir die Bedeutung dessen immer deutlicher und ich konnte während meiner Supervisionen mit Klienten meine Kompetenzen im interkulturellen Bereich erweitern und nun als Produkt anbieten. Ich musste oftmals feststellen, dass der Aspekt der interkulturellen Sensibilität sich nicht für alle als selbstverständlich erweist. Daher wünsche ich mir, auch mit diesem Text, der eine Kurzfassung meiner Abschlussarbeit im Rahmen der Weiterbildung ist, einen Beitrag dazu zu leisten, andere auf das Thema aufmerksam zu machen. Es geht also darum, auch in der Supervision anzuerkennen, dass die Unterschiedlichkeit des einzelnen Individuums respektiert, wertgeschätzt und in seiner Einzigartigkeit umso mehr als Bereicherung angesehen wird, sodass unsere Vielfalt zum Wachstum beiträgt.
Gibson, Adam; Cooper, Mick; Rae, John; Hayes, Jacqueline	2020	Clients' experiences of shared decision making in an integrative psychotherapy for depression	Journal of evaluation in clinical practice	26	2	559-568	Abstract Mental health and general health care research has shown that practitioners can facilitate patient involvement in shared decision making (SDM) and that the approach can benefit patients who wish to take part in decisions around their care. Yet patient experiences of SDM within a psychotherapy context have been little researched. This study examined how clients experienced SDM in a collaborative-integrative psychotherapy. A grounded theory approach used interpersonal process recall interviewing and supplementary semi-structured interviews to investigate 14 clients' experiences of SDM in pluralistic psychotherapy for depression. Verbatim transcripts were coded into 819 meaning units across six

							<p>categories containing 13 subcomponents that comprised a single, core category. The six categories were (a) experiencing decisions as shared, (b) psychotherapists supporting clients to become more active in the decision-making process, (c) both parties presenting and recognizing expert knowledge, (d) clients felt recognized as an individual and accommodated for by their psychotherapist, (e) clients felt comfortable engaging with the decision-making process, and (f) daunting for clients to be asked to take part in decision discussions. A core category emerged of ?Psychotherapists encourage client participation and progressively support clients to provide information and contributions towards shared treatment decisions that could be led equally, or marginally more by one party.? Such support was particularly useful when clients had difficulty contributing as part of decision discussions. Client preferences for SDM change across clients and across decisions, highlighting the importance of practitioners remaining flexible to individual clients when using the approach.</p>
Gidhagen, Ylva; Holmqvist, Rolf; Philips, Björn	2018	Attachment style among outpatients with substance use disorders in psychological treatment	Psychology and psychotherapy	91	4	490–508	<p>OBJECTIVES: To explore the associations between self-rated attachment style, psychological distress and substance use among substance use disorder (SUD) outpatients in psychological treatment. DESIGN AND METHODS: In this practice-based study, 108 outpatients were asked to fill in the Experiences in Close Relationships - Short form, the Clinical Outcomes in Routine Evaluation - Outcome Measure (CORE-OM), the Alcohol Use Disorders Identification Test (AUDIT), and the Drug Use Disorders Identification Test (DUDIT) at treatment start and end. Patients were given psychological treatments with a directive, reflective or supportive orientation. RESULTS: An insecure attachment</p>

							<p>style was more common among the SUD outpatients, compared to non-clinical groups. Patients with a fearful attachment style scored higher on psychological distress than patients with a secure attachment style. The associations between the attachment dimensions and psychological distress were stronger than those between attachment and SUD. Significantly more patients had a secure attachment style at treatment end.</p> <p>CONCLUSIONS: This study shows significant relations between patients' attachment style and their initial psychological distress. The causal relationship between attachment style and psychological distress is, however, not clear and can likely go in both directions. The psychological treatment of patients with SUD contributed significantly to changes from insecure to secure attachment style. PRACTITIONER POINTS: We found among patients with SUD a strong relation between patients' attachment style and their psychological distress. Knowledge of the patient's attachment style may help the therapist to tailor the treatment to the patient's needs. A change from insecure to secure attachment style can be an important goal for a SUD treatment, as it may prevent the patient from using defence strategies involving substance use for regulating emotions and interpersonal relationships.</p>
Gieselmann, Astrid; Scholten, Matthé; Gather, Jakob; Vollmann, Jochen	2019	Advance research directives in the context of dementia research: Ethical reflections on	Fortschritte der Neurologie-Psychiatrie	87	4	255–258	<p>In November 2016, the German Federal Diet adopted an amendment to the German Medicinal Products Act (Arzneimittelgesetz), which permits non-therapeutic biomedical research on incompetent adults under a number of strict conditions. One of these conditions is that the potential research participant has declared her wish to participate in biomedical research in a valid research advance directive. Before completing the</p>

		the disclosure requirement					research advance directive, the potential research participant must be informed about the circumstances of research participation. It has been argued that the legislature should have omitted the disclosure requirement for research advance directives. In this article, we consider reasons for maintaining such a disclosure requirement. In addition, we propose a practically feasible disclosure standard for research advance directives. According to this standard, potential research participants should be informed about types of biomedical studies rather than about particular studies.
Gill, Michelle M.; Ndimbii, James N.; Otieno-Masaba, Rose; Ouma, Millicent; Jabuto, Stella; Ochanda, Boniface	2022	Adherence challenges and opportunities for optimizing care through enhanced adherence counseling for adolescents with suspected HIV treatment failure in Kenya	BMC health services research	22	1	962	BACKGROUND: Adolescents living with HIV (ALHIV) experience higher mortality and are more likely to have poor antiretroviral therapy (ART) adherence and unsuppressed viral load (VL) compared to adults. Enhanced adherence counseling (EAC) is a client-centered counseling strategy that aims to identify and address barriers to optimal ART use and can be tailored to the unique needs of adolescents. This study aimed to better understand adherence barriers among ALHIV with suspected treatment failure and their experience with EAC to inform future programming. METHODS: A qualitative study was conducted in Homa Bay and Turkana counties, Kenya in 2019 with adolescents and caregivers of children and adolescents living with HIV with suspected treatment failure after ≥ 6 months on ART and who had received ≥ 1 EAC sessions. Sixteen focus group discussions (FGDs) were conducted; five FGDs each were held with adolescents 12-14 years (n = 48) and 15-19 years (n = 36). Caregivers (n = 52) participated in six FGDs. Additionally, 17 healthcare workers providing pediatric/adolescent HIV services participated in in-depth interviews. Audio recordings were transcribed and

							translated from Kiswahili or Dholuo into English and coded using MAXQDA software. Data were thematically analyzed by participant group. RESULTS: Participants identified adolescents' fear of being stigmatized due to their HIV status and their relationship with and level of support provided by caregivers. This underpinned and often undermined adolescents' ART-taking behavior and progress towards more independent medication management. Adolescents were generally satisfied with EAC and perceived it to be important in improving adherence and reducing VL. However, problems were noted with facility-based, individual EAC counseling, including judgmental attitudes of providers and difficulties traveling to and keeping EAC clinic appointments. Participant-suggested improvements to EAC included peer support groups in addition to individual counseling, allowing for greater flexibility in the timing and location of sessions and greater caregiver involvement. CONCLUSIONS: The findings provide opportunities to better tailor EAC interventions to promote improved ALHIV adherence and caregiver-supported disease management. Multi-prong EAC interventions that include peer-led and community approaches and target adolescent and caregiver treatment literacy may improve EAC delivery, address issues contributing to poor adherence, and position adolescents to achieve viral suppression. TRIAL REGISTRATION: ClinicalTrials.gov : NCT04915469.
Girit, Selina; Müller-Stierlin, Annabel S.; Hiltensperger, Ramona;	2023	Successful Implementation of Peer Support for People with Severe Mental	Psychother Psychosom Med Psychol	73	2	70-77	OBJECTIVE: Peer support is an established intervention in which people with mental illness receive support by trained peer support workers who have already overcome a mental health crisis. The implementation of peer support is complex due to interacting factors and can be

<p>Wenzel, Lisa; Lohner, Manfred; Mahlke, Candelaria; Nixdorf, Rebecca; Puschner, Bernd</p>		<p>Illness in Germany: a Theory of Change Approach</p>				<p>achieved through the participatory Theory of Change method. Aim of this study is to develop a cross-site Theory of Change for the sustainable implementation of UPSIDES peer support in Germany. METHODS: Based on site-specific Theories of Change workshops from Ulm and Hamburg in which 47 participants took part, a cross-site Theory of Change was designed and verified in three follow-up workshops with 12 participants. Participants' professional and experiential backgrounds were diverse, including peer support workers, hospital directors and managers, mental health professionals (psychiatrists, psychotherapists, nurses), and researchers. RESULTS: The first pathway of the cross-site Theory of Change focuses on the training of peer support workers, whereas the second pathway emphasizes recognition and integration by mental health institutions and professionals. The third pathway specifies the building of a cross-professional care network to integrate various peer support services. Procedures to approach prospective peer clients are depicted in the fourth pathway. The fifth path addresses the clarification of the role description of peer support workers and the implementation in other institutions through cooperation. DISCUSSION: Many of the identified implementation steps have been validated in comparable studies. The development of this Theory of Change by bringing together multiple perspectives of key stakeholders is an important basis for the sustainable implementation of UPSIDES peer support. Furthermore, it may serve as a blueprint for the implementation of similar interventions to advance scaling-up of evidence-based user-led and recovery-oriented interventions. CONCLUSION: The Theory of Change approach is a well-accepted and</p>
---	--	--	--	--	--	---

							feasible method, which can be recommended for the implementation of complex interventions such as UPSIDES peer support.
Gladstone, Tracy R. G.; Feinstein, Rebecca T.; Fitzgibbon, Marian L.; Schiffer, Linda; Berbaum, Michael L.; Lefaiver, Cheryl; Pössel, Patrick; Diviak, Kathleen; Wang, Tianxiu; Knepper, Amanda K.; Sanchez-Flack, Jennifer; Rusiewski, Calvin; Potts, Diane; Buchholz, Katherine R.; Myers, Taylor L.; van Voorhees, Benjamin W.	2022	PATH 2 Purpose: Design of a comparative effectiveness study of prevention programs for adolescents at-risk for depression in the primary care setting	Contemporary clinical trials	117		106763	The majority of mental, emotional, and behavioral (MEB) disorders have an initial onset before age 24, with 20% annual incidence, and with major depressive disorder (MDD) being the most common MEB. Health systems may be able to reduce costs by transitioning from the current treatment-focused model for MDD to a prevention model. However, evidence is needed for (1) the comparative effectiveness of a "scalable intervention" and (2) an implementation model for such a scalable intervention in the primary care setting. This paper describes a comparative effectiveness trial evaluating the efficacy of two evidence-based cognitive-behavioral prevention (CBP) programs: Teens Achieving Mastery over Stress (TEAMS), the "gold standard," group therapy model, and Competent Adulthood Transition with Cognitive Behavioral, Humanistic and Interpersonal Training (CATCH-IT), a scalable, self-directed, technology-based model. Eligible adolescents, age 13-19, are offered one of these two depression prevention programs across five health systems (30 clinics) in urban and suburban Chicago, IL, rural Western IL, and Louisville, KY. We are comprehensively evaluating patient-centered outcomes and stakeholder-valued moderators of effect versus baseline at two, six, 12, and 18-month assessment points. Using a hybrid clinical trial design that simultaneously examines the implementation process, the study is also assessing adolescents', parents', and providers' experiences (e.g., efficacy, time commitment, cultural acceptability) within each intervention approach.

Glanzer, Otto; Krauskopf, Karsten; Orkibi, Hod; Schnabel, Konrad; Stadler, Christian	2023	Zukunft der Psychodramath erapieforschung . Interviews mit Otto Glanzer, Karsten Krauskopf, Hod Orkibi und Christian Stadler	Zeitschrift fr Psychodrama und Soziometrie	22	1	35–51	Dieser Artikel der Zeitschrift fr Psychodrama und Soziometrie entht ein Interview von vier Experten zum derzeitigen Stand und zu mglichen zuknftigen Entwicklungen der Psychodramatherapieforschung. Die Interviewten blicken aus unterschiedlichen Perspektiven der Gestalttherapie, der Dramatherapie und der analytischen beziehungsweise tiefenpsychologischen Psychotherapie auf Herausforderungen und originr psychodramatische Anstze der Psychodramatherapieforschung. Besondere Bercksichtigung finden Aspekte der Outcome- und Prozess-Forschung, der Gruppentherapie, der Bedeutung von Kreativitt und Spontaneitt und der mentalisationsbasierten Psychotherapie als ein methodenbergreifendes Konzept. Auerdem werden Wege aufgezeigt, um die Forschung verstrkt in Ausbildung und praktische therapeutische Ttigkeit zu integrieren. Die Interviews verdeutlichen, dass eine verbesserte Kooperation der Forschenden und praktisch Ttigen dazu beitragen kann, die besonderen Potenziale der Psychodramatherapie herauszuarbeiten. Dadurch kann es gelingen, den Stellenwert des Psychodramas als eigenstndiges psychotherapeutisches Verfahren insgesamt auszubauen und zu behaupten.
Glaserapp, Jan	2021	Emotionen als Ressourcen. Manual fr Psychotherapie, Coaching und Beratung					In einem Manual fr Psychotherapie, Coaching und Beratung wird die Nutzung von Emotionen als Ressourcen dargestellt. Im Anschluss an Ausfhrungen zu Emotionen und zum Umgang mit ihnen werden sechs Module zum Einbezug von Emotionen in das psychotherapeutische Vorgehen beschrieben. Ziel ist dabei, dem Klienten den Zugang zu seinem eigenen emotionalen Erleben zu erleichtern. Ein Schwerpunkt liegt auf dem Erkennen und Offenlegen vermiedener Emotionen. Das Manual ist

							strungsbergreifend in der Einzel- sowie Gruppentherapie, Supervision und Selbsterfahrung einsetzbar. Fr die zweite Auflage wurde das Manual mit allen Arbeitsmaterialien vollstndig bearbeitet. - Inhalt: https://d-nb.info/1231245875/04
Glavonic, Emilija; Mitic, Milos; Adzic, Miroslav	2022	Hallucinogenic drugs and their potential for treating fear-related disorders: Through the lens of fear extinction	Couns and Psychother Res (Counselling and Psychotherapy Research)	100	4	947–969	Abstract Fear-related disorders, mainly phobias and post-traumatic stress disorder, are highly prevalent, debilitating disorders that pose a significant public health problem. They are characterized by aberrant processing of aversive experiences and dysregulated fear extinction, leading to excessive expression of fear and diminished quality of life. The gold standard for treating fear-related disorders is extinction-based exposure therapy (ET), shown to be ineffective for up to 35% of subjects. Moreover, ET combined with traditional pharmacological treatments for fear-related disorders, such as selective serotonin reuptake inhibitors, offers no further advantage to patients. This prompted the search for ways to improve ET outcomes, with current research focused on pharmacological agents that can augment ET by strengthening fear extinction learning. Hallucinogenic drugs promote reprocessing of fear-imbued memories and induce positive mood and openness, relieving anxiety and enabling the necessary emotional engagement during psychotherapeutic interventions. Mechanistically, hallucinogens induce dynamic structural and functional neuroplastic changes across the fear extinction circuitry and temper amygdala's hyperreactivity to threat-related stimuli, effectively mitigating one of the hallmarks of fear-related disorders. This paper provides the first comprehensive review of hallucinogens' potential to alleviate symptoms of fear-related disorders by focusing

							on their effects on fear extinction and the underlying molecular mechanisms. We overview both preclinical and clinical studies and emphasize the advantages of hallucinogenic drugs over current first-line treatments. We highlight 3,4-methylenedioxymethamphetamine and ketamine as the most effective therapeutics for fear-related disorders and discuss the potential molecular mechanisms responsible for their potency with implications for improving hallucinogen-assisted psychotherapy.
Gldenring, Annette; Stern, K.	2020	100 Jahre - Von Magnus Hirschfeld zur S3-Leitlinie und darber hinaus: Krperorientierte Behandlungsverfahren als eine Option der Zukunft?	Zeitschrift fr Sexualforschung	33	3	164-168	In diesem Beitrag werden zentrale Inhalte der 2018 verffentlichten S3-Leitlinie "Geschlechtsinkongruenz, Geschlechtsdysphorie und Trans-Gesundheit", die sich dem Wissen von Magnus Hirschfeld vor 100 Jahren wieder annhert, vorgestellt und diskutiert. Der zweite Teil widmet sich krper- und emotionsfokussierten Verfahren in der Versorgung von geschlechtlich nonkonformen Menschen, die bislang nur randstndig im therapeutisch-pdagogischen und beraterischen Bereich angewandt werden. Es wird dafr pldiert, krper- und emotionsfokussierte Verfahren in die Regelversorgung zu integrieren; insbesondere - wie in den AWMF-Kriterien vorgeschrieben - mit Blick auf die bevorstehende bearbeitung der S3-Leitlinie nach fnf Jahren in 2023. Dieser Zeitpunkt gibt auch die Chance, die in der aktuellen Leitlinie verwendete Sprache weiter zu entgendern, um mit einer geschlechtsinkluisiven Nomenklatur nicht-binrem Geschlechtererleben gerecht zu werden. Glisenti, Kevin; Strodl, Esben; King, Robert	2018	Emotion-focused therapy for binge-eating disorder: A	Clinical psychology & psychotherapy	25	6	842-855	This study aimed to provide preliminary evidence of the usefulness of emotion-focused therapy (EFT) for binge-eating disorder (BED). We used a single-subject design in which 12weeks of individual EFT were applied

		review of six cases					<p>nonconcurrently to six female adult participants with BED, following three weekly baseline sessions. Participants were assessed for binge-eating psychopathology and emotion regulation difficulties on a weekly basis during baseline and treatment. They were assessed on a 2-, 4-, and 8-week basis during posttreatment, and they were assessed for binge-eating episodes, eating disorder attitudes, alexithymia, and psychiatric comorbidity at pretreatment and posttreatment. All cases experienced reliable recovery from binge-eating psychopathology and a significant decrease in binge-eating frequency. For all cases, there was reliable improvement or recovery on eating and shape concerns, and there was improvement on weight concern for the majority of cases. For all cases, reliable recovery or improvement occurred in overall emotion regulation. Most cases that were in the clinical range pretreatment recovered for anxiety, and reliable improvement in or recovery from depression occurred for all cases. There was reliable recovery or improvement in alexithymia for half of the cases; however, the other half experienced no change or deteriorated. There were no treatment dropouts. Individual EFT demonstrates potential as a psychological treatment for BED. The current study provides preliminary evidence to guide the development of a more extensive trial to test the efficacy of individual EFT for BED as well as to identify possible mechanisms of change. 2018 John Wiley & Sons, Ltd.</p>

		Therapy for Binge-Eating Disorder					
Glock, Gianna; Hilsenroth, Mark; Curtis, Rebecca	2018	Therapeutic interventions patients with anxiety problems find most helpful: A case for integration?	Journal of Psychotherapy Integration	28	2	233–241	<p>Little research has examined what patients find most helpful with regard to their improvements during treatment. This study explores what specific therapeutic interventions people find most helpful regardless of the type of therapy they receive, and specifically focuses on patients seeking treatment for anxiety symptoms as their primary concern. Data was collected from 34 outpatients reporting high levels of distress related to anxiety symptoms. Patients rated the helpfulness of different psychodynamic–interpersonal and cognitive–behavioral therapist interventions during their treatment, and these ratings were examined for a relationship to overall improvement. Significant findings included exploring wishes, fantasies, dreams or early memories ($r = .472, p = .005$); exploring uncomfortable feelings ($r = .443, p = .009$); focusing on future life situations ($r = .428, p = .012$); feelings and perceptions are linked to past experiences ($r = .400, p = .019$); practicing behaviors learned in therapy between sessions ($r = .345, p = .046$); and providing information on symptoms, treatment, disorder ($r = .341, p = .048$). Trends toward significance between the rated helpfulness of the following therapist interventions with improvement in their therapy included providing explicit advice or direct suggestion ($r = .338, p = .051$) and exploring alternative understanding of patient experiences ($r = .320, p = .065$). Our findings suggest there are specific techniques in both psychodynamic–interpersonal and cognitive–behavioral approaches important during the change process of patients suffering from anxiety problems. This supports future research</p>

							examining transtheoretical or integrative approaches in the psychotherapy of anxiety. (PsycINFO Database Record (c) 2018 APA, all rights reserved)
Göbel, Kristin; Ortelbach, Niklas; Cohrdes, Caroline; Baumgarten, Franz; Meyrose, Ann-Katrin; Ravens-Sieberer, Ulrike; Scheithauer, Herbert	2022	Co-occurrence, stability and manifestation of child and adolescent mental health problems: a latent transition analysis	BMC psychology	10	1	267	<p>BACKGROUND: Complex constellations of socio-emotional and behavioural problems (i.e., mental health problems) in childhood and adolescence are common and heighten the risk for subsequent personality, anxiety and mood disorders in adulthood. Aims of this study included the examination of patterns of mental health problems (e.g., externalizing-internalizing co-occurrence) and their transitions to reported mental disorders by using a longitudinal person-centered approach (latent class and latent transition analysis). METHODS: The sample consisted of 1255 children and adolescents (51.7% female, mean age = 12.3 years, age range 8-26 years) from three time points of the comprehensive mental health and wellbeing BELLA study. Children and their parents completed the German SDQ (Strength and Difficulties Questionnaire, Goodman, 1997) and reported on diagnoses of ADHD, depression, and anxiety. RESULTS: Latent class analysis identified a normative class, an emotional problem class, and a multiple problem class. According to latent transition analysis, the majority of the sample (91.6%) did not change latent class membership over time; 14.7% of individuals showed a persistent pattern of mental health problems. Diagnoses of mental disorders were more likely to be reported by individuals in the emotional problem or multiple problem class. CONCLUSIONS: Results highlight the need for early prevention of mental health problems to avoid accumulation and manifestation in the transition to adolescence and young adulthood.</p>

<p>Gobin, Robyn L.; Strauss, Jennifer L.; Golshan, Shahrokh; Allard, Carolyn B.; Bomyea, Jessica; Schnurr, Paula P.; Lang, Ariel J.</p>	<p>2019</p>	<p>Gender Differences in Response to Acceptance and Commitment Therapy Among Operation Enduring Freedom/Operation Iraqi Freedom/Operation New Dawn Veterans</p>	<p>Women's health issues : official publication of the Jacobs Institute of Women's Health</p>	<p>29</p>	<p>3</p>	<p>267-273</p>	<p>BACKGROUND Most of our knowledge base regarding treatment response among veterans comes from predominantly male samples. Evidence suggests, however, that women and men use different coping strategies, which may impact how effective treatments are for people of different genders. The purpose of this investigation was to examine gender differences in response to acceptance and commitment therapy, an empirically supported transdiagnostic psychotherapy.</p> <p>METHODS Data were drawn from a multisite, randomized, controlled trial of acceptance and commitment therapy as compared with a psychotherapy control, namely, present-centered therapy (PCT), in veterans with emotional distress who served in Operations Enduring Freedom, Iraqi Freedom, or New Dawn (OEF/OIF/OND). Although the original trial did not find a difference between acceptance and commitment therapy and present-centered therapy, we were interested in examining whether gender differences may have been obscured in the original analyses. This secondary analysis included 117 participants for whom at least one post-baseline data point was available and examined the role of gender in treatment response.</p> <p>RESULTS Gender differences were not observed on the primary outcome of general distress, but were observed in post-traumatic stress disorder symptoms ($p < .01$).</p> <p>CONCLUSIONS These preliminary results suggest the possibility of gender differences in psychotherapy response and should motivate additional study of gender-specific care.</p>

Gocheva, Vanya; Hund-Georgiadis, Margret; Hediger, Karin	2018	Effects of animal-assisted therapy on concentration and attention span in patients with acquired brain injury: A randomized controlled trial	Neuropsychology	32	1	54–64	<p>Objective: Previous studies have reported that brain-injured patients frequently suffer from cognitive impairments such as attention and concentration deficits. Numerous rehabilitation clinics offer animal-assisted therapy (AAT) to address these difficulties. The authors' aim was to investigate the immediate effects of AAT on the concentration and attention span of brain-injured patients. Method: Nineteen patients with acquired brain injury were included in a randomized, controlled, within-subject trial. The patients alternately received 12 standard therapy sessions (speech therapy, physiotherapy, occupational therapy) and 12 paralleled AAT sessions with comparable content. A total of 429 therapy sessions was analyzed consisting of 214 AAT and 215 control sessions. Attention span and instances of distraction were assessed via video coding in Noldus Observer. The Mehrdimensionaler Befindlichkeitsbogen ([Multidimensional Affect Rating Scale] MDBF questionnaire; Steyer, Schwenkmezger, Notz, & Eid, 1997) was used to measure the patient's self-rated alertness. Concentration was assessed through Visual Analogue Scale (VAS) via self-assessment and therapist's ratings. Results: The patients' attention span did not differ whether an animal was present or not. However, patients displayed more instances of distraction during AAT. Moreover, patients rated themselves more concentrated and alert during AAT sessions. Further, therapists' evaluation of patients' concentration indicated that patients were more concentrated in AAT compared with the control condition. Conclusions: Although the patients displayed more instances of distraction while in the presence of an animal, it did not have a negative impact on their attention span. In addition, patients reported to</p>
--	------	--	-----------------	----	---	-------	--

							be more alert and concentrated when an animal was present. Future studies should examine other attentional processes such as divided attention and include neurobiological correlates of attention. (PsycINFO Database Record (c) 2018 APA, all rights reserved)
Goeddel, Lee A.; Murphy, Zachary; Owodunni, Oluwafemi; Esfandiary, Tina; Campbell, Demetria; Shay, Joanne; Tang, Olive; Bandeen- Roche, Karen; Gearhart, Susan; Brown, Charles H. [4th.]	2023	Domains of Frailty Predict Loss of Independence in Older Adults After Noncardiac Surgery	Annals of surgery	278	2	e226- e233	IMPORTANCE: Preoperative frailty has been consistently associated with death, severe complications, and loss of independence (LOI) after surgery. LOI is an important patient-centered outcome, but it is unclear which domains of frailty are most strongly associated with LOI. Such information would be important to target individual geriatric domains for optimization. OBJECTIVE: To assess whether impairment in individual domains of the Edmonton Frail Scale (EFS) can predict LOI in older adults after noncardiac surgery. DESIGN: Retrospective Cohort Study. SETTING: One Academic Hospital. PARTICIPANTS: Patients aged 65 or older who were living independently and evaluated with the EFS during a preoperative visit to the Center for Preoperative Optimization at the Johns Hopkins Hospital between June 2018 and January 2020. MAIN OUTCOME: LOI defined as discharge to increased level of care outside of the home with new mobility deficit or functional dependence. New mobility deficit and functional dependence were extracted from chart review of the standardized occupational therapy and physical therapy assessment performed before discharge. RESULTS: A total of 3497 patients were analyzed. Age (mean±SD) was 73.4±6.2 years, and 1579 (45.2%) were female. The median total EFS score was 3 (range 0-16), and 725/3497 (27%) were considered frail (EFS≥6). The frequencies of impairment in each EFS domain were functional performance (33.5% moderately impaired, 11% severely impaired), history of hospital readmission

							(42%), poor self-described health status (37%), and abnormal cognition (17.1% moderately impaired, 13.8% severely impaired). Overall, 235/3497 (6.7%) patients experienced LOI. Total EFS score was associated with LOI (odds ratio: 1.37, 95% CI, 1.30-1.45, P <0.001) in a model adjusted for age, sex, body mass index, American Society of Anesthesiologists rating, congestive heart failure, valvular heart disease, hypertension diagnosis, chronic lung disease, diabetes, renal failure, liver disease, weight loss, anemia, and depression. Using a nested log likelihood approach, the domains of functional performance, functional dependence, social support, health status, and urinary incontinence improved the base multivariable model. In cross-validation, total EFS improved the prediction of LOI with the final model achieving an area under the curve of 0.840. Functional performance was the single domain that most improved outcome prediction, but together with functional dependence, social support, and urinary incontinence, the model resulted in an area under the curve of 0.838. CONCLUSION AND RELEVANCE: Among domains measured by the EFS before a wide range of noncardiac surgeries in older adults, functional performance, functional dependence, social support, and urinary incontinence were independently associated with and improved the prediction of LOI. Clinical initiatives to mitigate LOI may consider screening with the EFS and targeting abnormalities within these domains.
Goel, Anurag R.; Bruce, Haley A.; Williams, Nicholas;	2021	Long-Term Effects of Hearing Aids on Hearing Ability in Patients with	Journal of the American Academy of Audiology	32	6	374-378	BACKGROUND: A frequent concern surrounding amplification with hearing aids for patients with sensorineural hearing loss is whether these devices negatively affect hearing ability. To date, there have been few studies examining the long-term effects of

<p>Alexiades, George</p>		<p>Sensorineural Hearing Loss</p>				<p>amplification on audiometric outcomes in adults. PURPOSE: In the present study, we examined how hearing aids affect standard audiometric outcomes over long-term periods of follow-up. RESEARCH DESIGN: We retrospectively collected audiometric data in adults with sensorineural hearing loss, constructing a model of long-term outcomes. STUDY SAMPLE: This retrospective cohort study included 802 ears from 401 adult patients with bilateral sensorineural hearing loss eligible for amplification with hearing aids at a single institution. INTERVENTION: Of the eligible patients, 88 were aided bilaterally, and 313 were unaided. DATA COLLECTION AND ANALYSIS: We examined the standard three-frequency pure-tone average (PTA(3-Freq)), a novel extended pure-tone average (PTA(Ext)), and word recognition score (WRS) per-ear at each encounter. We then modeled the association between the use of hearing aids for 5 years and these audiometric outcomes using targeted maximum likelihood estimation. RESULTS: In comparing aided and unaided ears at the end of 5 years, there were discernible effects for all measurements. The PTA(3-Freq) was 5 dB greater in aided ears (95% CI: 1.37-8.64, p = 0.007), WRS was 4.5 percentage points lower in aided ears (95% CI: -9.14 to 0.15, p = 0.058), and PTA(Ext) was 5 dB greater in aided ears (95% CI: 2.18-7.82, p < 0.001), adjusting for measured confounders. CONCLUSION: Our analysis revealed discernible effects of 5 years of hearing aid use on hearing ability, specifically as measured by the PTA(3-Freq), novel PTA(Ext), and WRS, suggesting a greater decline in hearing ability in patients using hearing aids. Future studies are needed to examine these effects between treatment groups over longer periods of time and in more heterogeneous populations</p>

							to improve clinical practice guidelines and safety of both prescriptive fitting nonprescriptive amplification.
Goeres, Achim; Hetzer, Tanja	2016	Transformation und kollektive Traumatisierung	Bewusstseinswi ssenschaften	22	2	66–82	<p>Informiert wird über N-Prozess-Moderation, eine Weiterentwicklung der Prozessarbeit nach Arnold Mindell. In diesem Ansatz wird die gesellschaftliche Transformation als ein sich selbst organisierender Prozess eines hochkomplexen Systems betrachtet. Die interdisziplinäre Verbindung von chaostheoretischen Erkenntnissen, Prozessarbeit und Erfahrungen aus der Trauma-Therapie legen nahe, dass kollektive Traumatisierungen, allen voran die Traumata des Holocausts und des Zweiten Weltkrieges, die wichtigsten Widerstände gegen die Kräfte der Selbstorganisation mobilisieren. Das Wissen um Trauma-Dynamiken fordert, dass die Persönlichkeitsanteile, welche die traumatisierenden Erfahrungen und Gefühle bewahren, eine doppelte Unterstützung benötigen, bevor nachhaltiger Wandel geschehen kann: Sie brauchen öffentliches Mitgefühl und die Unterstützung von Vertretern einer transzendenten Qualität. Damit dies möglich wird, müssen einzelne Menschen, allen voran die Facilitator(inn)en von gesellschaftlichem Wandel, sowohl ihre eigenen Traumatisierungen in mitfühlende Obhut nehmen als auch den Zugang zu ihren eigenen inneren transzendenten Quellen erschließen. Die neuentwickelte Methode "SlowFlow" ermöglicht das Fühlen und Durcharbeiten dieser inneren Prozesse inmitten einer Gruppe von realen Menschen in einem kollektiv traumatisierten Umfeld.</p>
Goetz, Dana B.; Hirschhorn, Elizabeth W.	2022	An Evaluation of an ACT-Based "Aging Resiliently" Group	Clinical gerontologist	45	2	430–436	<p>OBJECTIVES: There were two quality improvement aims in this project: (1) to evaluate the outcomes of a six-week closed geriatric focused Acceptance and Commitment Therapy (ACT)-based group called "Aging Resiliently" offered in a primary care setting, and (2) to obtain</p>

							<p>feedback from group members in order to make relevant modifications to future groups. METHODS: Four cohorts of veterans ages 58 and older participated in the group (N = 17). Paired samples t-tests were computed to determine the significance of changes on pre- and post-self-report measures of depression, experiential avoidance, and life satisfaction. Veterans also provided feedback in the form of an open-ended feedback questionnaire. RESULTS: There were statistically significant improvements in depressive symptoms and satisfaction with life, but not in experiential avoidance. Two major themes emerged from the feedback questionnaire about what group members found to be the most helpful: (1) self-reflection/values, and (2) the social process of the group. CONCLUSIONS: At our institution, the Aging Resiliently group yielded meaningful outcomes for older veterans presenting with different problems related to aging. CLINICAL IMPLICATIONS: This Aging Resiliently group proved to be a potential effective, feasible, and acceptable psychotherapy for older veterans in our established local primary care setting.</p>
Goetz, Teddy G.; Wolk, Courtney Benjamin	2023	Moving toward targeted eating disorder care for transgender, non-binary, and gender expansive patients in the United States	The International journal of eating disorders	56	12	2210–2222	<p>Abstract Objective Literature suggests that transgender, non-binary, and/or gender expansive (TNG) people are more likely than cisgender peers to experience eating disorders (EDs) and engage in dangerous weight control behaviors. TNG individuals with EDs are dramatically higher risk for self-harm behaviors, suicidal ideation, and suicidal behaviors than cisgender peers with EDs or TNG peers without EDs, and often engage in ED symptoms/behaviors to alleviate gender dysphoria. Yet, no treatment paradigms have yet been adapted for TNG-specific ED care. This qualitative study aims to identify stakeholder needs from such care to inform future</p>

						<p>clinical interventions. Methods We elicited patient (n=?12) and mental health clinician (n=?9) stakeholder needs and preferences regarding TNG-specific ED care. Semi-structured interview guides informed by the Consolidated Framework for Implementation Research (CFIR) and a behavioral insights framework, EAST, were developed to ensure uniform inclusion and sequencing of topics and allow for valid comparison across interviews. Using a rapid analysis procedure, we produced a descriptive analysis for each group identifying challenges of and opportunities in providing ED care for TNG adults. Results Stakeholders expressed needs and preferences for TNG-specific treatment including that it be: (1) TNG-affirming, weight-inclusive, trauma-informed, and anti-racist; (2) delivered by an interdisciplinary team, including gender-affirming care clinicians; (3) focused on parsing gender dysphoria from other body image concerns, building distress tolerance, and working toward gender euphoria (rather than body acceptance). Discussion Future work is needed exploring ED care delivery models that integrate gender-affirming care services with mental health care. Such models may improve TNG access to ED treatment and recovery. Public Significance Transgender, non-binary, and/or gender expansive (TNG) experience disproportionately high rates of eating disorders and have unique barriers to accessing care. In individual interviews, TNG adults with eating disorders and mental health clinicians who provide psychotherapy for eating disorders voiced desire for greater availability of TNG-affirming, weight-inclusive eating disorder care, integrated with other gender-affirming care services. This informs future research developing eating disorder care for TNG individuals.</p>

Gofman, Mordechai; Kivity, Yogev; Peri, Tuvia	2022	Beyond the conditioned fear model: Narrative reconstruction for a woman with posttraumatic stress disorder	Journal of Psychotherapy Integration	32	2		<p>Although fear is considered to be the dominant affect associated with posttraumatic stress disorder (PTSD), recent changes in diagnostic criteria have resulted in the addition of anger, guilt, and shame as significant emotional states linked with the disorder. The presence of these other emotions is associated with poorer prognosis, slower recovery, and more residual symptoms. However, treatment strategies for these other kinds of PTSD presentation have been less well explored than fear. Narrative reconstruction—an integrative treatment for PTSD—combines components of cognitive behavioral therapy, such as exposure and cognitive restructuring, alongside psychodynamic features. Incorporated psychodynamic elements include the expression of emotions, identification of recurring themes and patterns, interpersonal relationships, the influence of past experiences, and the integration of dissociated emotional schemas. During narrative reconstruction, the patient and therapist reconstruct an organized, coherent, and detailed written narrative of the patient’s traumatic experience. Narrative reconstruction employs psychodynamic elements to help identify and address the underlying feelings of shame, guilt, and anger. To illustrate how these other emotions are dealt with in narrative reconstruction, a case study is presented of a woman with chronic PTSD who previously had limited success with exposure-based treatment. Unprocessed shame, anger, and loneliness are discovered, and connections are made to past and current family situations. Pre- to posttreatment, session-by-session, and follow-up data on clinician-administered and self-report measures demonstrate significant symptom reduction. Clinical vignettes and a case discussion demonstrate the</p>

							therapeutic model and technique. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Goicoechea, Jessie	2022	A tribute to Constance Fischer: Collaboration, social responsibility, and aesthetics	The Humanistic Psychologist	50	3	417–424	This article gives tribute to Constance Fischer, PhD, ABPP. Constance Fischer has had an outstanding impact on the development of humanistic psychology. She pioneered individualized, collaborative assessment, an approach that privileges the client’s lived experiences, agency, and contributions to the interpretation of test data. She brought these same values to qualitative research, another area of scholarship and training for which she is very well known. In both assessment and research, Constance Fischer has sought to understand and describe in everyday language the meaning that situations hold for people, to respect and engage clients and research participants as coparticipants, and to address the interpersonal and social contexts in which a presenting problem or phenomenon of research interest occurs and is coconstructed. This tribute centers on Constance Fischer’s embodiment and appreciation, both professionally and personally, of several of the elements she identified as core to humanistic assessment— collaboration, intervention, and context or artful hospitality. This tribute also situates these elements as consistent with a feminist epistemology. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Gökçe İsbir, Gözde; Yılmaz, Mualla; Thomson, Gill	2022	Using an emotion-focused approach in preventing psychological birth trauma	Perspectives in psychiatric care	58	3	1170–1176	<p>PURPOSE</p> <p>This discussion article considers how an emotion-focused approach can be adopted to prevent psychological birth trauma and to optimize perinatal wellbeing for women and their families.</p> <p>CONCLUSION</p> <p>Emotion-focused approaches have a different perspective when compared to other classic</p>

						<p>psychotherapy methods. This approach may help women to resolve the negative impacts of psychological birth trauma; to prevent posttraumatic stress disorder onset; to lead to better results for mother and baby well-being; and may be cost effective.</p> <p>PRACTICE IMPLICATIONS</p> <p>Mental health nurses/midwives should receive education about emotion-focused approaches in addition to gaining competence in basic counseling skills so that they can utilize these approaches with women.</p>
Goldbach, Nele; Reif, Andreas; Preuss, Hanna; Erhart, Mira; Zabel, Kirsten; Windmann, Sabine; Oertel, Viola		A randomized trial of group therapy for resource activation for patients with affective disorder	Journal of Psychotherapy Integration	33	1	<p>Resource activation is a common factor of psychotherapy and has an effect on the treatment success regardless of the specific orientation. A balanced focus on resources and problems seems to constitute a promising therapy method. Therefore, the aim of this study was to evaluate the effects of a novel group therapy for resource activation (GTRA) for inpatients with unipolar depressive and bipolar affective disorders experiencing a depressive episode. Primary outcome criteria were the change in resources and in depression severity. Eighty-nine patients with unipolar depressive and bipolar affective disorders (57.3% female, mean age = 39.9 years) took part in a randomized, controlled trial comparing GTRA plus treatment as usual (TAU) with TAU alone. A comparison of the intervention (GTRA plus TAU) and control group (TAU) showed significantly higher improvements over time in “current relationships” and “fostering self-esteem” in the intervention group but no significant group differences in depression severity. Over the course of the GTRA, participants reported positive experiences of coping and clarification and showed significant increases in problem activation and improvements in subjective session outcomes. This study can be understood as a preliminary</p>

							effort to pave the way for further refinement and testing of GTRA for patients with affective disorders in addition to TAU in an inpatient care setting. Future research should focus on improving the efficacy of the GTRA by varying different therapy components (e.g., the duration of the GTRA). (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Goldberg, Simon B.; Babins-Wagner, Robbie; Miller, Scott D.	2017	Nurturing Expertise at Mental Health Agencies				199–217	
Goldin, Philippe R.; Morrison, Amanda; Jazaieri, Hooria; Brozovich, Faith; Heimberg, Richard; Gross, James J.	2016	Group CBT versus MBSR for social anxiety disorder: A randomized controlled trial	Journal of consulting and clinical psychology	84	5	427–437	Objective: The goal of this study was to investigate treatment outcome and mediators of cognitive-behavioral group therapy (CBGT) versus mindfulness-based stress reduction (MBSR) versus waitlist (WL) in patients with generalized social anxiety disorder (SAD). Method: One hundred eight unmedicated patients (55.6% female; mean age = 32.7 years, SD = 8.0; 43.5% Caucasian, 39% Asian, 9.3% Hispanic, 8.3% other) were randomized to CBGT versus MBSR versus WL and completed assessments at baseline, posttreatment/WL, and at 1-year follow-up, including the Liebowitz Social Anxiety Scale—Self-Report (primary outcome; Liebowitz, 1987) as well as measures of treatment-related processes. Results: Linear mixed model analysis showed that CBGT and MBSR both produced greater improvements on most measures compared with WL. Both treatments yielded similar improvements in social anxiety symptoms, cognitive reappraisal frequency and self-efficacy, cognitive distortions, mindfulness skills, attention focusing, and rumination. There were greater decreases in subtle avoidance behaviors following CBGT

							<p>than MBSR. Mediation analyses revealed that increases in reappraisal frequency, mindfulness skills, attention focusing, and attention shifting, and decreases in subtle avoidance behaviors and cognitive distortions, mediated the impact of both CBGT and MBSR on social anxiety symptoms. However, increases in reappraisal self-efficacy and decreases in avoidance behaviors mediated the impact of CBGT (vs. MBSR) on social anxiety symptoms. Conclusions: CBGT and MBSR both appear to be efficacious for SAD. However, their effects may be a result of both shared and unique changes in underlying psychological processes. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>
Goldman, Rhonda; Goldstein, Zoë	2022	Case formulation in emotion-focused therapy	Journal of clinical psychology	78	3	436-453	<p>Case formulation in emotion-focused therapy aids therapists to both conceptualize core emotion schemes and follow markers across therapy that signify tasks aimed at emotional transformation. The case formulation process will be illustrated in the successful case of Jina, a woman with a history of childhood emotional abuse who sought therapy for depression. The three stages of case formulation are co-constructed between client and therapist. In stage one, the therapist assesses her initial emotion processing style and listens as the emotion-based narrative unfolds. In stage two, the core emotion scheme and formulation narrative organize around feelings of shame of inferiority and attachment-related feelings of being rejected and unloved. Attendant secondary emotions of powerlessness, and unmet needs for validation emerge. Stage three evolves as the therapist follows process markers, prompting chair work for both unfinished business and self-criticism, ultimately helping Jina access adaptive sadness and newly experienced self-compassion.</p>

Goldstein, Shari E.	2017	Reflexivity in narrative research: Accessing meaning through the participant-researcher relationship	Qualitative Psychology	4	2	149-164	The purpose of this article is to provide an example of a study in which reflexivity served as a secondary but integral data source and became the experiential context from which meaningful findings emerged. I will briefly describe the purpose and methodology of the project, a phenomenological narrative study in which I interviewed 7 women previously diagnosed with borderline personality disorder (BPD) about their therapy relationship experiences (Goldstein, 2014). A description of my reflexive process, including planned and unplanned activities, is provided along with a discussion of the challenges associated with engaging and communicating reflexive methods. My experience of 3 participants along with the intersubjective reflections (Finlay, 2002) that unfolded during the interviews and in later analysis, are used to demonstrate the transformative quality of the reflexive material and how the cocreated relationships contextualized the content of the narratives with a shared, lived experience. It is argued that the reflexive process supported the emergence of findings that more usefully captured the dyadic nature of the interpersonal tensions that develop between individuals placed in this diagnostic group and their therapists. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Goldstein, Shari E.	2020	Hear us! Seven women diagnosed with borderline personality disorder describe what they need from	Qualitative Psychology		23 26- 35 98(Ele ctr oni c), 23	132-152	The purpose of my dissertation project was to explore the interpersonal therapy experiences of seven female participants diagnosed with borderline personality disorder (BPD) using a phenomenological approach with participants' narratives as the primary data source. Data was gathered from individual interviews, administration of the core conflictual relationship theme-relationship anecdotes paradigm interview (CCRT-RAP; Luborsky, 1990), and relational space mapping (Josselson, 1996).

		their therapy relationships			26-3601(Print)	<p>The analysis involved a back-and-forth process whereby I moved between the developmental information, identified interpersonal patterns, described therapy experiences, and my own reflections. Immersion with the material was ongoing and allowed themes to be modified and elaborated. Results are described in a manner intended to illustrate the benefits of a phenomenological approach that relied heavily on participants' voices and allowed for continual reflection on the material and deepening of meaning. As a group, the seven participants desired therapists who demonstrated caring and kindness and who joined them in their experiences through a deep form of listening and validation. These conditions were necessary but not adequate for the development of a healing alliance. Participants also desired clinicians who maintained a collaborative approach, balancing strength with flexibility, and who were willing to address conflicts and tensions head-on. Therapist neutrality, withholding, and inactivity were experienced as aversive and participants expressed a desire for explicit evidence of clinician humanity. The value of the qualitative approach for accessing the complex and vacillating therapy relationship needs of this patient group is discussed. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>
Gollner, Christina	2018	Psychosenpsychotherapie				<p>Die Psychotherapie der Psychose wird unter Rückgriff auf ihre historische Entwicklung errtert. Dabei wird den Begriffen der "Verrcktheit" und des "Wahnsinns" nachgegangen und auf tiefsitzende Vorurteile und ngste bei vielen Menschen Bezug genommen. Der Schizophreniebegriff wird diskutiert, und das Konzept der "Basisstrungen" wird detailliert fr verschiedene Zustandsbereiche erlutert: (1) Verlust der Kontrolle</p>

							(Verlust der Selbstverfügbarkeit), (2) einfache (sensorische) Wahrnehmung, (3) komplexe (organisierte) Wahrnehmung, (4) Sprache (expressiv und rezeptiv), (5) Denken, (6) Gedchtnis, (7) Motorik, (8) Automatismenverlust, (9) Anhedonie und Angst (Depressivitt), (10) Reizberflutung. Es wird darauf eingegangen, wie diese Phnomene aus gestalttherapeutischer Sicht zu verstehen sind. Die Wichtigkeit des Milieus als auslsender oder aufrechterhaltender Faktor wird betont.
Golovchanova, Nadezhda; Dezutter, Jessie; Vanhooren, Siebrecht	2021	Meaning profiles and the perception of the working alliance at the start of outpatient person-centered, experiential, and existential psychotherapies	Journal of clinical psychology	77	3	770–781	OBJECTIVE(S): Quantitative research on meaning in life in the context of psychotherapy is relatively limited. The current study aims to investigate the profiles of the meaning of clients and their perception of the working alliance and initial symptomatology at the start of therapy. DESIGN: In a sample of 145 clients (62.1% female; mean age, 34.77) who started person-centered psychotherapy, the relationship between meaning, search for meaning, symptomatology, and the working alliance was analyzed. The assessment took place after the second session. RESULTS: Cluster analysis revealed four profiles: Low Presence High Search, High Presence Low Search, High Presence High Search, and Low Presence Low Search. These meaning profiles are distinguished in terms of symptomatology but not in terms of the working alliance perception. However, the experience of meaning is significantly associated with the working alliance. CONCLUSIONS: Results show the relevance of meaning-related questions for certain groups of clients at the start of therapy.
Gómez Penedo, Juan Martín; Constantino,	2019	Baseline Client Interpersonal Agency	Behavior therapy	50	6	1063–1074	In a recent trial for generalized anxiety disorder (GAD), cognitive-behavioral therapy (CBT) integrated with motivational interviewing (MI) promoted more long-term

<p>Michael J.; Coyne, Alice E.; Romano, Felicia M.; Westra, Henny A.; Antony, Martin M.</p>		<p>Moderates the Indirect Effect of Treatment on Long-term Worry in Variants of CBT for Generalized Anxiety Disorder</p>				<p>worry reduction than CBT alone (Westra, Constantino, & Antony, 2016). A follow-up analysis found that CBT vs. MI-CBT clients evidenced greater increases in friendly submissiveness (FS) across treatment, which in turn promoted lower long-term worry (Constantino, Romano, Coyne, Westra, & Antony, 2018). It was unsurprising that traditional directive CBT promoted more FS than when person-centered MI was integrated; however, given that problematic low agency characterizes GAD, that greater FS promoted better outcome was unexpected. To further unpack this unexpected result, we tested the following moderated mediation hypothesis: for clients with more vs. less problematic low agency at baseline, CBT would still promote more in-session FS than MI-CBT, but this increase would in turn predict increased worry over follow-up. Clients receiving CBT (n = 43) or MI-CBT (n = 42) rated their interpersonal problems at baseline and their worry after treatment and across 12-month follow-up. Therapists rated clients' in-session FS multiple times. As predicted, multilevel modeling revealed that for clients with more problematic low agency, CBT vs. MI-CBT facilitated greater FS, which in turn related to increased worry across follow-up. For clients with more problematic high agency, CBT's facilitation of greater FS related to reduced worry across follow-up. A baseline interpersonal problem characteristic of GAD may have implications for treatment matching and for appreciating different pathways to long-term improvement, or deterioration, for different GAD subgroups.</p>
<p>Gómez Penedo, Juan Martín; Coyne, Alice E.; Constantino,</p>		<p>Theory-specific patient change processes and mechanisms in</p>	<p>Journal of consulting and clinical psychology</p>	<p>88</p>	<p>8</p>	<p>Objective: This study aimed to identify differential patient change processes and mechanisms associated with long-term outcome in exposure-based cognitive therapy (EBCT) and cognitive-behavioral therapy (CBT) for</p>

<p>Michael J.; Krieger, Tobias; Hayes, Adele M.; grosse Holtforth, Martin</p>		<p>different cognitive therapies for depression</p>				<p>depression. Method: We drew on a randomized controlled trial in which 149 patients were randomly assigned to either EBCT or CBT, with the treatments showing comparable efficacy at 12-month follow-up (grosse Holtforth et al., 2019). Based on Doss's (2004) 4-step model of psychotherapy change and using sequential multilevel structural equation models, we tested putative theory-based change processes and mechanisms for both treatments. Specifically, we examined emotional processing and cognitive restructuring during treatment as hypothesized change processes of EBCT and CBT, respectively. Furthermore, as potential change mechanisms during follow-up, we examined theory-relevant mechanisms for each treatment, preselected via multilevel models. Results: Although the full serial mediational pathways were not supported, EBCT fostered greater during-treatment increases in emotional processing and higher self-efficacy during follow-up than CBT, both of which associated with better long-term depression outcome. Unexpectedly, cognitive restructuring change did not differ between EBCT and CBT. Across both CBT and EBCT, greater during-treatment increases in cognitive restructuring related to lower cognitive-behavioral avoidance and greater self-efficacy across follow-up, which associated with lower long-term depression. Conclusions: Results suggest that therapists might improve long-term depression outcome by fostering both emotional processing (via emotion-focused techniques as included in EBCT) and cognitive restructuring (by using general CBT techniques included in both treatments), which operate either directly or through varied treatment-common mechanisms (e.g., greater self-efficacy and reduced cognitive-behavioral</p>

Gonçalves, Miguel M.; Silva, Joana Ribeiro; Mendes, Inês; Rosa, Catarina; Ribeiro, António P.; Batista, João; Sousa, Inês; Fernandes, Carlos F.	2017	Narrative Changes Predict a Decrease in Symptoms in CBT for Depression: An Exploratory Study	Clinical psychology & psychotherapy	24	4	835–845	<p>OBJECTIVE Innovative moments (IMs) are new and more adjusted ways of thinking, acting, feeling and relating that emerge during psychotherapy. Previous research on IMs has provided sustainable evidence that IMs differentiate recovered from unchanged psychotherapy cases. However, studies with cognitive behavioural therapy (CBT) are so far absent. The present study tests whether IMs can be reliably identified in CBT and examines if IMs and symptoms' improvement are associated.</p> <p>METHODS The following variables were assessed in each session from a sample of six cases of CBT for depression (a total of 111 sessions): (a) symptomatology outcomes (Outcome Questionnaire-OQ-10) and (b) IMs. Two hierarchical linear models were used: one to test whether IMs predicted a symptom decrease in the next session and a second one to test whether symptoms in one session predicted the emergence of IMs in the next session.</p> <p>RESULTS Innovative moments were better predictors of symptom decrease than the reverse. A higher proportion of a specific type of IMs-reflection 2-in one session predicted a decrease in symptoms in the next session. Thus, when clients further elaborated this type of IM (in which clients describe positive contrasts or elaborate on changes processes), a reduction in symptoms was observed in the next session.</p> <p>DISCUSSION A higher expression and elaboration of reflection 2 IMs</p>

							<p>appear to have a facilitative function in the reduction of depressive symptoms in this sample of CBT. Copyright © 2016 John Wiley & Sons, Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Elaborating innovative moments (IMs) that are new ways of thinking, feeling, behaving and relating, in the therapeutic dialogue, may facilitate change. IMs that are more predictive of amelioration of symptoms in CBT are the ones focused on contrasts between former problematic patterns and new adjusted ones; and the ones in which the clients elaborate on processes of change. Therapists may integrate these kinds of questions (centred on contrasts and centred on what allowed change from the client's perspective), in the usual CBT techniques. When elaborating these IMs successfully, therapists may expect an improvement in symptoms in the next session of psychotherapy.</p>
Gondek, Dawid; Edbrooke-Childs, Julian; Velikonja, Tjasa; Chapman, Louise; Saunders, Felicity; Hayes, Daniel; Wolpert, Miranda	2017	Facilitators and Barriers to Person-centred Care in Child and Young People Mental Health Services: A Systematic Review	Clinical psychology & psychotherapy	24	4	870–886	<p>Implementation of person-centred care has been widely advocated across various health settings and patient populations, including recent policy for child and family services. Nonetheless, evidence suggests that service users are rarely involved in decision-making, whilst their preferences and goals may be often unheard. The aim of the present research was to systematically review factors influencing person-centred care in mental health services for children, young people and families examining perspectives from professionals, service users and carers. This was conducted according to best practice guidelines, and seven academic databases were searched. Overall, 23 qualitative studies were included. Findings from the narrative synthesis of the facilitators and barriers are discussed in light of a recently published systematic review examining person-centred care in</p>

						<p>mental health services for adults. Facilitators and barriers were broadly similar across both settings. Training professionals in person-centred care, supporting them to use it flexibly to meet the unique needs of service users whilst also being responsive to times when it may be less appropriate and improving both the quantity and quality of information for service users and carers are key recommendations to facilitate person-centred care in mental health services with children, young people and families. Copyright © 2016 John Wiley & Sons, Ltd. KEY PRACTITIONERS MESSAGES: As research shows, children and young people are rarely actively involved in their treatment within mental health services. This is despite a strong recent emphasis on providing care within child and young people mental health services according to person-centred principles. Still, there is little known about factors affecting provision of person-centred care with this population. As found by the current study, the most commonly reported factors affecting provision of person-centred care were information sharing (in an appropriate amount and at a right time), listening, respecting and validating, quality of relationship and support, capacity of children and young people to be involved in their care, parental involvement and shortage of resources. These factors were cited as both facilitators and barriers and were found to be universally important by service users, their carers and professional working at the services. The key factors were broadly similar to those reported among adults, particularly regarding information sharing/communication, capacity of service users to be involved and available resources. The main difference was related to a more complex role of a carer in children/young people services. The key</p>
--	--	--	--	--	--	---

							recommendations of the review to improve provision of person-centred care are providing professionals with more training in using the approach, supporting them to use it flexibly to meet the unique needs of service users whilst also being responsive to times when it may be less appropriate and improving both the quantity and quality of information for service users.
Gone, Joseph P.	2022	Re-imagining mental health services for American Indian communities: Centering Indigenous perspectives	American journal of community psychology	69	3-4	257-268	The Indigenous peoples of North America are heirs to the shattering legacy of European colonization. These brutal histories of land dispossession, military conquest, forced settlement, religious repression, and coercive assimilation have robbed American Indian communities of their economies, lifeways, and sources of meaning and significance in the world. The predictable consequence has been an epidemic of "mental health" problems such as demoralization, substance abuse, violence, and suicide within these communities. One apparent solution would seem to be the initiation or expansion of mental health services to better reach American Indian clients. And yet, conventional mental health services such as counseling and psychotherapy depend on assumptions and aspirations that may not fit well with American Indian cultural sensibilities. For example, counseling practices draw on the presumed value for clients of introspective and expressive "self talk," whereas Indigenous community norms may emphasize communicative caution outside of interactions with intimate kin, leading to marked reticence rather than candid disclosure. Moreover, given community sensitivities to salient histories of colonization, such differences have the potential to further alienate American Indian community members from the very services and providers designated to help them. In this article, I review a postcolonial predicament

							that bedevils American Indian community mental health services and trace a program of research that has sought to harness American Indian cultural and spiritual traditions for reimagining helping services in a manner that truly centers Indigenous perspectives.
Gonzalez Salas Duhne, Paulina; Horan, Andrew J.; Ross, Caitlin; Webb, Thomas L.; Hardy, Gillian E.	2020	Assessing and promoting the use of implementation intentions in clinical practice	Social science & medicine (1982)	265		113490	<p>RATIONALE: Striving for goals is a key part of psychological therapy, but people often struggle to translate their goals into action. Prior evidence has found that forming if then plans (or 'implementation intentions') is an effective way to bridge the gap between goals and action. However, it is unclear if therapists naturally prompt their clients to form implementation intentions and, if not, whether training would be feasible. METHOD AND RESULTS STUDY 1: Researchers coded the behavior change techniques used in 40 sessions of therapy for depression using a Cognitive Behavioral Therapy approach and a Person-Centered Experiential Therapy approach and found that therapists do not typically prompt their clients to form implementation intentions in either therapeutic approach. METHOD AND RESULTS STUDIES 2 AND 3: The aim was to develop and evaluate a training program for therapists on implementation intentions. Training was delivered face-to-face to 69 cognitive-behavioral therapists (Study 2), and online to 87 therapists working across models (Study 3) and therapists completed self-report measures of their use and knowledge of implementation intentions before training, post-training, and follow-up. The training significantly increased therapists' use and knowledge of implementation intentions. CONCLUSIONS: Taken together, these findings suggest therapists can be trained in the use of implementation intentions and that</p>

							appropriate content might be integrated into training programs.
Goodall, Gemma; Taraldsen, Kristin; Serrano, J. Artur	2021	The use of technology in creating individualized, meaningful activities for people living with dementia: A systematic review	Dementia (London, England)	20	4	1442–1469	<p>There is a growing interest in using technology to provide meaningful activities for people living with dementia. The aim of this systematic review was to identify and explore the different types of digital technologies used in creating individualized, meaningful activities for people living with dementia. From 1414 articles identified from searches in four databases, 29 articles were included in the review. The inclusion criteria were the study used digital technology to deliver an individually tailored activity to participants with dementia, the process of individualization was described, and findings relating to the mental, physical, social, and/or emotional well-being of the participant were reported. Data extracted from the included studies included participant demographics, aims, methods, and outcomes. The following information on the technology was also extracted: purpose, type, training, facilitation, and the individualization process. A narrative synthesis of the results grouped the various technologies into four main purposes: reminiscence/memory support, behavior management, stimulating engagement, and conversation/communication support. A broad range of technologies were studied, with varying methods of evaluation implemented to assess their effect. Overall, the use of technology in creating individualized, meaningful activities seems to be promising in terms of improving behavior and promoting relationships with others. Furthermore, most studies in this review involved the person with dementia in the individualization process of the technology, indicating that research in this area is adopting a more co-creative and inclusive approach.</p>

						<p>However, sample sizes of the included studies were small, and there was a lack of standardized outcome measures. Future studies should aim to build a more concrete evidence base by improving the methodological quality of research in this area. Findings from the review indicate that there is also a need for more evidence concerning the feasibility of implementing these technologies into care environments.</p>
<p>Goodman, Fallon R.; Peckham, Andrew D.; Kneeland, Elizabeth T.; Choate, Alexandria M.; Daniel, Katharine E.; Beard, Courtney; Björgvinsson, Thröstur</p>	2023	<p>How does emotion regulation change during psychotherapy? A daily diary study of adults in a transdiagnostic partial hospitalization program</p>	<p>Journal of consulting and clinical psychology</p>	91	12	<p>Objective: Improvement in emotion regulation is a proposed transdiagnostic mechanism of change. However, treatment research is limited by disorder-specific investigations that assess a narrow number of emotion regulation strategies. Moreover, most assess pre-to-post-treatment change without examining short-term changes throughout psychotherapy that might influence treatment response. Method: To address these gaps, this study uses daily diary methodology to examine trajectories of change in use of six emotion regulation strategies during partial hospitalization psychiatric treatment. Treatment was rooted in cognitive behavioral principles and included skills adapted from empirically supported cognitive behavioral therapy (CBT) and dialectical behavior therapy (DBT) manuals. Participants were adults (N = 364; Mage = 34.6 years; 60% female; 85% non-Hispanic White) with various profiles of mood, anxiety, and obsessive-compulsive disorders who completed symptom measures at baseline and discharge and daily measures of emotion regulation. Results: In the first 7 treatment days, patients increased use of engagement strategies (reappraisal, acceptance) and decreased use of disengagement (expressive suppression) and cognitive perseveration (experiential avoidance, rumination) strategies. Day-to-day trajectories</p>

						found that decreased use of experiential avoidance predicted next-day changes in distraction and suppression use. In predicting treatment outcomes, steeper rates of decreased suppression use predicted reductions in anxiety, depression, and general psychopathology symptoms; similar patterns were observed for decreased rumination and experiential avoidance use and increased reappraisal use. Conclusion: Results add to a growing literature on the value of intentional, constructive engagement with emotional experiences as a mechanism of psychological health. Goodman, Geoff; Halfon, Sibel	2021	Session adherence to prototypical psychotherapy process as a correlate of outcome in a naturalistic study of child mentalization-informed psychodynamic play therapy	Journal of Psychotherapy Integration	31	4	While the adult psychotherapy literature has made great strides to understand the relations between psychotherapy process and treatment outcome, the child psychotherapy literature lags far behind. The first aim of this study was to determine whether mentalization-informed psychodynamic play therapy (PDT) sessions adhered to therapeutic principles comprising this treatment model. The second aim was to assess whether session adherences to prototypical PDT and Reflective Function (RF) process using the Child Psychotherapy Q-Set (CPQ) were correlated with both problem behavior reduction and adaptive functioning after controlling for pretreatment scores. The third aim was to assess whether these correlations depended on problem behavior type (externalizing-only, internalizing-only, externalizing and internalizing), age, or gender. The sample included 95 children (56% male; M age = 6.80) categorized into these 3 types. Three-hundred seventy-nine sessions from different treatment phases were rated using the CPQ. Outcomes were assessed using the Child Behavior

							<p>Checklist, Teacher Rating Form, Emotion Regulation Checklist, and Children's Global Assessment Scale. Sessions adhered to prototypical RF and PDT process. Session adherences to prototypical RF and cognitive-behavioral therapy (CBT) process were positively correlated with adaptive functioning. Among internalizers, session adherence to prototypical PDT process was negatively correlated with internalizing behavior, while among externalizers, session adherences to prototypical RF and CBT process were negatively correlated with externalizing behavior and emotion negativity. Session adherences to prototypical RF and CBT process were significantly higher for girls than for boys. Two different "trajectories of success" are proposed for children with externalizing problems. PDT is proposed for children with internalizing problems. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Görg, Nora; Böhnke, Jan R.; Priebe, Kathlen; Rausch, Sophie; Wekenmann, Stefanie; Ludäscher, Petra; Bohus, Martin; Kleindienst, Nikolaus	2019	Changes in Trauma-Related Emotions Following Treatment With Dialectical Behavior Therapy for Posttraumatic Stress Disorder After Childhood Abuse	J. Traum. Stress (Journal of Traumatic Stress)	32	5	764-773	<p>Dialectical behavior therapy for posttraumatic stress disorder (DBT-PTSD) is a trauma-focused therapy shown to reduce core PTSD symptoms, such as intrusions, hyperarousal, and avoidance. Preliminary data indicate effects on elevated trauma-related emotions (e.g., guilt and shame) and possibly radical acceptance of the traumatic event. However, it is unclear if improvements in these variables are significant after controlling for changes in core PTSD symptoms and to what extent nonclinical levels are obtained. In the current study, 42 individuals who met criteria for PTSD after childhood abuse and were participating in a 3-month residential DBT-PTSD program were evaluated at the start of the exposure phase of DBT-PTSD and the end of treatment; a nonclinical sample with a history of childhood abuse was the reference group. Multivariate analyses of variance and</p>

						<p>multivariate analyses of covariance controlling for change in core PTSD symptoms were used to evaluate changes in several elevated trauma-related emotions (fear, anger, guilt, shame, disgust, sadness, and helplessness) and in radical acceptance. In a repeated measures multivariate analyses of variance, both elevated trauma-related emotions and radical acceptance significantly improved during DBT-PTSD, $\lambda = 0.34$, $p < .001$; $\eta^2 = .56$; $t(40) = -5.66$, $p < .001$, $SMD = 0.88$, even after controlling for changes in PTSD symptoms, $\lambda = 0.35$, $p < .001$, $\eta^2 = .65$; $\Lambda = 0.86$, $p = .018$, $\eta^2 = .14$, respectively. Posttreatment, 31.0% (for acceptance) to 76.2% (for guilt) of participants showed nonclinical levels of the investigated outcomes, suggesting that both trauma-related emotions and radical acceptance changed after the 3-month residential DBT-PTSD program.</p> <p>Spanish Abstracts by Asociación Chilena de Estrés Traumático (ACET) Los Cambios en las Emociones Relacionadas al Trauma posterior al Tratamiento con Terapia Dialéctica Conductual para el Trastorno de Estrés Traumático después de Abuso Infantil EMOCION RELACIONADA AL TRAUMA Y TERAPIA DIALECTICA CONDUCTUAL La terapia dialéctica conductual para el trastorno de estrés traumático (TDC-TEPT) es una terapia centrada en el trauma que ha mostrado una reducción de los síntomas centrales del TEPT, tales como intrusiones, hiperactivación, y evitación. Resultados preliminares indican efectos sobre elevadas emociones relacionadas con el trauma (por ej., culpa y vergüenza) y la aceptación posiblemente radical del evento traumático. Sin embargo, no es claro si las mejoras en estas variables son significativas luego de controlar los cambios en los síntomas centrales del TEPT y en qué medida se obtienen</p>
--	--	--	--	--	--	---

						<p>niveles no clínicos. En el presente estudio, 42 individuos que cumplieron con los criterios para el TEPT luego de un abuso infantil y que participaron en un programa residencial de la TDC-TEPT por 3 meses fueron evaluados al principio de su etapa de exposición a la TDC-TEPT y al final del tratamiento; una muestra no clínica con una historia de abuso infantil fue el grupo de referencia. Análisis multivariados de varianza y análisis multivariados de covarianza controlando los cambios en los síntomas centrales del TEPT fueron usados para evaluar los cambios en diferentes emociones relacionadas al trauma elevadas (temor, rabia, culpa, vergüenza, disgusto, tristeza, y desesperanza) y una aceptación radical. En los análisis multivariados de la varianza de medidas repetidas, las elevadas emociones relacionadas al trauma y la aceptación radical mejoraron significativamente durante la TDC-TEPT, $\lambda = 0.34$, $p < .001$; $\eta^2 = .56$; $t(40) = -5.66$, $p < .001$, $SMD = 0.88$, incluso luego de controlar por los cambios en los síntomas del TEPT, $\lambda = 0.35$, $p < .001$, $\eta^2 = .65$; $\Lambda = 0.86$, $p = .018$, $\eta^2 = .14$, respectivamente. Al término del tratamiento, 31.0% (para aceptación) al 76.2% (para culpa) de los participantes mostraron niveles no clínicos de los resultados investigados, sugiriendo que tanto las emociones relacionadas con el trauma como la aceptación radical, cambió luego del programa residencial de la TDC-TEPT por 3 meses.</p> <p>Traditional and Simplified Chinese Abstracts by the Asian Society for Traumatic Stress Studies (AsianSTSS) 簡體及繁體中文撮要由亞洲創傷心理研究學會翻譯 Changes in Trauma-related Emotions Following Treatment with Dialectical Behavior Therapy for Posttraumatic Stress Disorder after Childhood Abuse Traditional Chinese 標題:</p>

						<p>反映, 此疗法对提升了的创伤相关情绪 (如内疚、羞耻) 及有可能激进地接受创伤事件有所效应。然而, 我们仍不清楚这些变量的改善, 在对PTSD的核心症状改变作对照后是否仍为显著, 以及效应在非临床水平的可见程度有多大。研究样本为42名童年时经历虐待并符合患PTSD准则的人士。他们参与为期3个月的DBT-PTSD住院治疗计划, 在暴露阶段开始前及完成治疗后接受评估。我们采用一份童年时经历虐待的非临床样本作为参考组。我们对变异量和协方差进行多变量分析, 并以PTSD的核心症状改变作对照, 以评估几种提升了的创伤相关情绪的变化 (恐惧、愤怒、内疚、羞耻、厌恶、悲伤、无助), 及激进的接受的变化。重复进行的变异量多变量分析显示, 样本接受DBT-PTSD期间, 提升了的创伤相关情绪及激进的接受均有显著改善($\lambda = 0.34, p < .001; \eta^2 = .56; t(40) = -5.66, p < .001, SMD = 0.88$);即使对PTSD的症状改变作对照后, 依然如是($\lambda = 0.35, p < .001, \eta^2 = .65; \Lambda = 0.86, p = .018, \eta^2 = .14$)。完成治疗后, 31.0%的样本(在接受方面) 至 76.2%的样本(在内疚方面)呈现非临床水平的受检视效应, 反映样本的创伤相关情绪和激进的接受, 在完成为期3个月的DBT-PTSD住院治疗计划后, 有所改变。.</p>	
Gorrell, Sasha; Lebow, Jocelyn; Kinasz, Kathryn; Mitchell, James E.;	2020	Psychotropic medication use in treatment-seeking youth	European eating disorders review : the journal of the Eating	28	6	739-749	<p>OBJECTIVE Psychotropic medication use in youth with eating disorders (EDs) is poorly understood despite high co-occurrence of psychiatric disorders. This study examined characteristics associated with medication use in</p>

Goldschmidt, Andrea B.; Le Grange, Daniel; Accurso, Erin C.		with eating disorders	Disorders Association				<p>treatment-seeking youth with EDs.</p> <p>METHOD Youth up to age 18 reported on medication use when presenting to an academic medical center outpatient ED service in the United States. Data presented were collected between 1998-2015.</p> <p>RESULTS The sample (N = 604) was predominantly female (90.6%) with a mean age of 15.3 years (SD = 2.3). Approximately one-third (30%, n = 173) were taking psychotropic medications (40%, n = 70, were taking multiple medications). Antidepressant use was most common (26%, n = 152), followed by atypical antipsychotics (8%, n = 43). Adjusting for co-occurring psychiatric disorders, non-Hispanic Whites who had received prior treatment (psychotherapy, hospitalization) were significantly more likely to be using medication. Longer illness duration and prior treatment were associated with greater antidepressant use. For atypical antipsychotics, prior hospitalization was associated with greater use.</p> <p>CONCLUSIONS Findings confirm moderate psychotropic medication use among young patients with EDs despite a lack of clarity regarding optimally effective pharmacologic interventions in this population. Pharmacological trials examining the efficacy of medications for young patients with EDs are warranted to inform future prescribing practice.</p>
Gourari, Karim; Awada, Ahmad; Kotecki, Nuria	2022	Molecular oncology: what is needed to speed access to innovative therapies in	Current opinion in oncology	34	5	575-578	<p>PURPOSE OF REVIEW: A better understanding of the biology of cancer cells has led in the past 20 years to more and more molecular and immunological driven treatment strategies impacting both clinical trials and day-to-day practice. The aim of this review is to describe new approaches to conduct clinical trials in this area to</p>

		clinical research?					<p>speed up drug development and increase access to innovation for cancer patients. RECENT FINDINGS: The design of an early phase trial has an impact on its clinical benefit. Trials deriving from a specific biomarker or histologic characteristic (also known as enrichment design) are more likely to demonstrate benefit than trials based on a more conventional design. However, the increase of low incidence cancer molecular subtypes poses a major hurdle in the clinical management and drug development research for cancer patients.</p> <p>SUMMARY: With the identification of news targets and the subsequent introduction of precision medicine, new strategies and tools are needed to provide access to biomarker identification and target-oriented clinical trials to all cancer patients. We propose to set up a new patient-centered model to conduct clinical trials allowing simply to 'bring the trial to the patient'.</p>
Gozé, Tudi	2022	How to Teach/Learn Praecox Feeling? Through Phenomenology to Medical Education	Frontiers in psychiatry	13		819305	<p>BACKGROUND: The Praecox Feeling (PF) refers to a classical psychopathological concept describing the specific experience of bizarreness arising in the encounter with a person living with schizophrenia spectrum disorders (SSDs). Some studies have shown that experienced psychiatrists take advantage of this experience to perform accurate and rapid diagnostic expertise. It would seem that PF is not contradictory with an operationalized diagnostic approach, but that the PF would intervene at a more tacit level of medical judgment. However, the articulation between the implicit and explicit levels of the psychiatrist's experience in the situation of medical judgment remains little studied, even though it is of crucial importance for structuring the teaching of clinical psychiatry to mental health practitioners. Can diagnostic intuition be learned? Is this</p>

							<p>experience a kind of "gift" that some may or may not have? Does the PF refer to medical expertise? METHODS: To unfold the complexity of his questions this article proposes to conduct an historical, epistemological and phenomenological analysis of the PF. RESULTS: We will first conduct a presentation of historical descriptions of the PF understood as a sensation, intuition and experience, alongside the evolution of the concept of schizophrenia. Then, the article proposes an original phenomenological modelization of the temporal unfolding of the PF. DISCUSSION: The phenomenological conceptualization, informed from empirical evidence will try to account for the paradox of the PF as both lived evidence and indescribable experience. PF will be described as a complex cognitive and embodied process based upon ante-predicative aesthetic sensing which is secondly apprehended as perceptible evidence thanks to clinical typification. This conceptualization relying on Husserl manuscript on intersubjectivity will help to demystify its experiential structure and discuss its relevance for medical education.</p>

Graham, Christopher D.; Gouick, Joanna; Ferreira, Nuno; Gillanders, David	2016	The influence of psychological flexibility on life satisfaction and mood in muscle disorders	Rehabilitation Psychology	61	2	210–217	Purpose/Objective: Acceptance and commitment therapy (ACT), a newer type of behavior therapy that targets psychological flexibility, may have particular utility in the context of muscle disorders. However, there has been no formal investigation of psychological flexibility in this population. This longitudinal observational study investigated whether psychological flexibility is cross-sectionally related to, and prospectively influential on, life satisfaction and mood in muscle disorders. Methods: Data were collected via online questionnaire batteries, completed at baseline and then repeated 4 months later. Cross-sectional and prospective regression analyses examined relationships between validated measures of disability level, psychological flexibility (experiential avoidance, cognitive fusion, and valued living) and illness perceptions (a psychological variable with known influence in muscle disorders), and outcomes (life satisfaction, anxiety, and depression). Results: A sample of 137 people with a range of muscle disorders participated. In cross-sectional analyses, psychological flexibility explained significant unique variance in addition to illness perceptions ($\Delta R^2 = 0.17-0.34, p < .001$). In prospective analyses, psychological flexibility alone was

							<p>predictive of change in life satisfaction ($\Delta R^2 = 0.04$, $p = .01$) and anxiety ($\Delta R^2 = 0.03$, $p = .04$) over 4 months. No independent variables were predictive of change in depression over 4 months, and disability level had no significant influence on outcomes. Conclusions: Psychological flexibility influences important outcomes in muscle disorders. Experimental studies are required to establish if increased psychological flexibility leads to improved outcomes. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
<p>Grandjean, Loris; Hummel, Jana; Wyer, Dominik; Beuchat, H�el�ene; Caspar, Franz; Sachse, Rainer; Berger, Thomas; Kramer, Ueli</p>	2021	<p>Psychotherapeutic case formulation: Plan analysis for narcissistic personality disorder</p>	<p>Personality and mental health</p>	15	4	309–316	<p>Abstract Background One of the relevant case formulation methods for personality difficulties is plan analysis. The present study aimed at delivering a prototypical plan analysis for clients presenting with a diagnosis of narcissistic personality disorder (NPD). The sample consisted of 14 participants diagnosed with an NPD. Based on audio clinical material, we developed 14 individual plan analyses that we then merged into a single prototypical plan analysis. For explorative purposes, we ran an ordinary least squares regression model to predict the narcissistic symptoms severity (NAR) measured on a scale of 1-7 of the 14 clients by the presence (respectively absence) of certain plans in their individual plan analysis. The synthesis revealed that clients with pathological narcissism share common basic motives. Results of the regression model reveal that the presence of the plan 'be strong' reduces the NAR scale by 1.52 points ($p = .011$). Discussion In the treatment of psychological disorders, precise case formulations allow therapists for making clinically appropriate decision, personalizing the intervention and gaining insight into the client's subjective experience. In the prototypical plan structure we developed for NPD, clients strive to</p>

							strengthen their self-esteem and avoid loss of control, criticism and confrontation as well as to get support, understanding and solidarity. When beginning psychotherapy with a client presenting with NPD, the therapist can use these plans as valuable information to help writing tailored, and therefore more efficient, case formulations for their patients presenting with an NPD.
Graser, Johannes; Göken, Jonas; Lyons, Naomi; Ostermann, Thomas; Michalak, Johannes		Cognitive-behavioral therapy for adults with intellectual disabilities: A meta-analysis	Clinical Psychology: Science and Practice	29	3		People with intellectual disabilities (ID) often suffer from psychopathological symptoms and are rarely treated psychotherapeutically. Concurrently, there is a lack of studies summarizing the effectiveness of cognitive-behavioral therapy (CBT) for adults with ID and co-morbid psychopathological symptoms. A literature search identified CBT-trials focusing on the outcome domains anxiety, depression, and anger in adults with ID (IQ 20–69). A meta-analysis with subgroup analyses was conducted. Controlled trials showed significant effects for the outcome domains depression (d = 0.65; eight studies; 95% confidence interval, CI [0.24, 1.07]) and anger (d = 0.65; six studies; 95% CI [0.25, 1.06]), and a small and nonsignificant effect for anxiety (d = 0.25; four studies; 95% CI [0.00, 0.49]). Due to only a moderate number of trials and limited methodological quality, larger and more rigorous trials are needed to support the preliminary evidence for the efficacy of CBT for individuals with ID. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Graul, A.; Haggerty, A.; Stickley, C.; Kumar, P.; Morales, K.; Bogner, H.;	2020	Effect of patient education on palliative care knowledge and acceptability of outpatient	Gynecologic oncology	156	2	482–487	OBJECTIVES: A randomized control trial (RCT) to estimate the effect of an interventional video on improving palliative care knowledge, acceptability and attendance to outpatient services in gynecologic oncology patients. METHODS: Women receiving treatment for gynecologic malignancy recruited at an academic tertiary care center

Burger, R. A.; Morgan, M.; Ko, E.		palliative care services among gynecologic oncology patients: A randomized controlled trial					<p>were randomized to: palliative care educational video or non-directive cancer center video. The primary outcome was referral to palliative care. Function and knowledge were assessed using the Functional Assessment of Cancer Therapy and the Palliative Care Knowledge Scale. Data analyses were performed using t-tests, Wilcoxon rank sum or Fisher's exact tests with significance level of $\alpha = 0.05$. RESULTS: 111 women were enrolled. Demographic characteristics were equally distributed between groups with respect to age, race, cancer, and stage. There was no statistical difference in knowledge scores or in referral to palliative care between the patients that watched the educational versus control video (29% vs. 27%; $p = .79$). Secondary analysis showed a statistically significant increase in utilization of palliative care services compared to historic institutional data (8.8% to 31.5%; $p \leq .001$). Further, those referred had significantly worse baseline functional scores. CONCLUSIONS: Use of a palliative care educational video did not increase knowledge or acceptability of palliative services within this RCT. However, the rate of patients referred to palliative care tripled compared to historic rates. Further studies should investigate whether discussion regarding palliative care services alone may increase desire for referral, and if use of Fact-G scores may identify patients in greatest need of services.</p>
Graziano, Paulo A.; Spiegel, Jamie A.; Hayes, Timothy; Arcia, Emily	2023	Early intervention for families experiencing homelessness: A pilot randomized trial	Journal of consulting and clinical psychology	91	4	192–207	<p>Objective: As part of a larger community-based, service-driven research project, the primary purpose of this pilot randomized study was to examine the feasibility and acceptability of delivering time-limited adaptations of parent–child interaction therapy (PCIT) and child–parent psychotherapy (CPP) within a sample of children experiencing homelessness. The secondary goal was to</p>

		comparing two parenting programs				<p>examine the promise of both interventions in improving parent/child outcomes. Method: One hundred forty-four young children (18 month–5 years old; Mage = 3.48, SD = 1.09; 43.1% female; 78.5% Black/African American; 27.1% Hispanic) and their mothers were recruited from a women’s homeless shelter and randomly assigned to 12 weeks of either PCIT or CPP delivered by shelter clinicians on-site. Attendance, fidelity, and program satisfaction were obtained. Families completed pre- and postintervention assessments, including observational data on maternal verbalizations during a child-led play session. Results: Both time-limited PCIT and time-limited CPP were successfully implemented with similarly high levels of intervention fidelity (>90%) and satisfaction by mothers (85%). Completion rates were similar across both time-limited PCIT (76.6%) and time-limited CPP (71.4%). Both time-limited CPP and PCIT resulted in decreases in children’s posttraumatic stress, parental stress, and increases in maternal positive verbalizations. Only time-limited PCIT resulted in significant improvements in externalizing behavior problems in children and reductions in maternal negative verbalizations. Conclusions: Time-limited PCIT and CPP are acceptable, feasible, and hold significant promise for helping families within a homeless shelter environment and by extension, other transitional and/or shelter environments. A full randomized trial is warranted to determine which program may offer a more effective intervention. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Grecucci, Alessandro; Messina, Irene;	2020	A Dual Route Model for Regulating	Frontiers in psychology	11	930	<p>The aim of this article is to present recent applications of emotion regulation theory and methods to the field of psychotherapy. The term Emotion Regulation refers to the</p>

<p>Amodeo, Letizia; Lapomarda, Gaia; Crescentini, Cristiano; Dadomo, Harold; Panzeri, Marta; Theuninck, Anthony; Frederickson, Jon</p>		<p>Emotions: Comparing Models, Techniques and Biological Mechanisms</p>				<p>neurocognitive mechanisms by which we regulate the onset, strength, and the eventual expression of our emotions. Deficits in the regulation of emotions have been linked to most, if not all, psychiatric disorders, with patients presenting either dysregulated emotions, or dysfunctional regulatory strategies. We discuss the implications of regulating emotions from two different theoretical perspectives: the Cognitive Emotion Regulation (CER), and the Experiential-Dynamic Emotion Regulation (EDER) model. Each proposes different views on how emotions are generated, dysregulated and regulated. These perspectives directly influence the way clinicians treat such problems. The CER model views emotional dysregulation as due to a deficit in regulation mechanisms that prioritizes modifying or developing cognitive skills, whilst the EDER model posits emotional dysregulation as due to the presence of dysregulatory mechanisms that prioritizes restoring natural regulatory processes. Examples of relevant techniques for each model are presented including a range of cognitive-behavioral, and experiential (including both dynamic and cognitive) techniques. The aim of the paper is to provide a toolbox from which clinician may gain different techniques to enhance and maintain their patient's capacity for emotional regulation. Finally, the biological mechanisms behind the two models of emotion regulation are discussed as well as a proposal of a dual route model of emotion regulation.</p>
<p>Grecucci, Alessandro; Sigirci, Hseyin; Lapomarda, Gaia; Amodeo,</p>	<p>2020</p>	<p>Anxiety regulation: From affective neuroscience to clinical practice</p>	<p>Brain Sciences, 2020</p>			<p>According to psychoanalysis, anxiety signals a threat whenever a forbidden feeling emerges. Anxiety triggers defenses and maladaptive behaviors, thus leading to clinical problems. For these reasons, anxiety regulation is a core aspect of psychodynamic-oriented treatments to</p>

Letizia; Messina, Irene; Frederickson, Jon						help clients. In the present theoretical paper, we review and discuss anxiety generation and dysregulation, first from a neural point of view, presenting findings from neuroimaging and psychophysiological studies. The aim is to trace parallels with psychodynamic theories of anxiety. Then, we discuss the psychological mechanisms and neural bases of emotion regulation in the laboratory, and possible neurobiological mechanisms of anxiety regulation in psychotherapy. We describe two different approaches to emotion/anxiety regulation, one based on the standard cognitive model of emotion regulation, the other based on psychodynamic principles and affective neuroscience. We then illustrate in detail a dynamic experiential approach to regulation. This model claims that emotions arise before cognition and are not inherently dysregulated. Dysregulation emerges from co-occurrences of emotions and associated anxiety. Technical consequences of this model are discussed and include strategies to regulate anxiety.
Greenman, Paul S.; Johnson, Susan M.	2022	Emotionally focused therapy: Attachment, connection, and health	Current opinion in psychology	43	146-150	In this review, we suggest attachment science as a framework for understanding the negative impact of loneliness and social disconnection on mental and physical health and for guiding the interventions of clinicians. We provide an overview of current findings linking loneliness and social isolation to mental health problems such as depression and anxiety, as well as to physical illnesses such as heart disease. We propose emotionally focused therapy for couples, families, and individuals to enhance the quality of people's emotional ties to significant others and their subjective sense of social connectedness. We conclude by suggesting that the strengthening of emotional, interpersonal bonds, which is the primary focus of all forms of emotionally

							focused therapy, can help restore emotional balance, thereby protecting people from chronic feelings of isolation and the host of health problems that they can cause. Copyright 2021 Elsevier Ltd. All rights reserved.
Grégoire, Simon; Chénier, Christophe; Doucerain, Marina; Lachance, Lise; Shankland, Rebecca	2020	Ecological momentary assessment of stress, well-being, and psychological flexibility among college and university students during acceptance and commitment therapy	Canadian Journal of Behavioural Science / Revue canadienne des sciences du comportement	52	3	231–243	The aim of this ecological momentary assessment study was to explore how students' momentary levels of stress, well-being, and psychological flexibility fluctuate during an intervention based on acceptance and commitment therapy (ACT). Fifty-nine (n = 59) Canadian postsecondary students took part in this study. They were invited to participate in 5 group workshops of 2.5 hr in length and to use a smartphone application designed for ecological momentary assessment. Data collection spanned 5 consecutive weeks. Students were prompted once per day at random times between 8:30 a.m. and 8:30 p.m., for a maximum of 5 times per week and 25 intended prompts. Analyses were conducted using multilevel modeling. The results show that (a) students' momentary levels of stress, well-being, and psychological flexibility did not change significantly during the intervention; (b) students' momentary psychological flexibility was associated with their momentary stress and well-being; and (c) the association between students' momentary psychological flexibility and well-being became stronger over time. The results of this within-person research study extend previous between-person studies carried out on ACT and reinforce the importance of helping postsecondary students cultivate psychological flexibility to promote their mental health. (PsycInfo Database Record (c) 2021 APA, all rights reserved)
Grégoire, Simon; Lachance, Lise;	2016	L'efficacité de l'approche d'acceptation et	Canadian Journal of Behavioural	48	3	222–231	Many university students experience psychological health issues that undermine their academic success. In this quasi-experimental study, 90 (N = 90) students from 3

<p>Bouffard, Thérèse; Hontoy, Lysa-Marie; Mondehare, Laurence de</p>		<p>d'engagement en regard de la santé psychologique et de l'engagement scolaire des étudiants universitaires. [The effectiveness of the approach of acceptance and commitment with regard to the psychological health and academic engagement of university students.]</p>	<p>Science / Revue canadienne des sciences du comportement</p>				<p>universities in Quebec (Canada) participated in a group intervention based on Acceptance and Commitment Therapy (ACT). A pretest-posttest switching-replication design including 3 measuring times was used to evaluate the impact of the intervention on 1) psychological flexibility, 2) psychological health (stress, psychological wellbeing, anxiety and depression) and 3) academic commitment. Repeated measures ANCOVA demonstrate a positive effect of the intervention on students' psychological flexibility, their psychological health and their academic commitment. Results also show that gains related to psychological health and academic commitment are correlated with gains in terms of psychological flexibility. <p>Grenon, Renee; Schwartz, Dominique; Hammond, Nicole; Ivanova, Iryna; Mcquaid, Nancy; Proulx, Genevieve; Tasca, Giorgio A.</p>	<p>2017</p>	<p>Group psychotherapy for eating disorders: A meta-analysis</p>	<p>The International journal of eating disorders</p>	<p>50</p>	<p>9</p>	<p>997-1013</p>	<p>OBJECTIVE In the current meta-analysis, we review the effect of group psychotherapy compared to both wait-list controls and other active treatments for adults with eating disorders (EDs). METHOD Twenty-seven randomized controlled trials (RCTs) that provide direct comparisons with a total of 1,853 participants were included. RESULTS Group psychotherapy is significantly more effective than</p>

							<p>wait-list controls at achieving abstinence rates of binge eating and/or purging (RR = 5.51, 95% CI: 3.73, 8.12), decreasing the frequency of binge eating and/or purging (g = 0.70, 95% CI: 0.51, 0.90), and reducing related ED psychopathology (g = 0.49, 95% CI: 0.32, 0.66) after treatment. The effects of group psychotherapy and other active treatments (e.g., behavioral weight loss, self-help, individual psychotherapy) did not differ on any outcome at post-treatment or at follow-ups. Group cognitive behavioral therapy (CBT) and other forms of group psychotherapy did not differ significantly on outcomes at any time point.</p> <p>DISCUSSION</p> <p>Additional research is needed to evaluate other group psychotherapy approaches, along with CBT, to provide more evidence-based treatment options for individuals with an ED. Group psychotherapy appears as effective as other common treatments and is perhaps more cost-effective than the most popular treatment, individual psychotherapy. Only 8.33% of comparisons in the current meta-analysis had at least 80% power to detect a moderate effect (d = .50) and we recommend that future RCTs be adequately powered.</p>
Griffin, Darren K.	2022	Why PGT-A, most likely, improves IVF success	Reproductive biomedicine online	45	4	633–637	<p>Preimplantation genetic testing for aneuploidies (PGT-A), with its vocal advocates and opponents, is at the epicentre of a perpetual, often heated, debate. The main issues include the following. First, how do we interpret the existing evidence-base? Around 100 retrospective and single-centre studies, two non-selection trials and at least two meta-analyses point to its efficacy in improving live birth rates, although randomized controlled trials are more mixed. Second, what should be done in relation to euploid/aneuploid mosaicism? Recent data suggest that</p>

							low-level mosaic pregnancies can proceed uneventfully to term, so intelligent interpretation of the diagnostic data is appropriate. Third, what is the stance of the Human Fertilisation and Embryology Authority? The 'traffic light' system is much debated and is perhaps best described as well-intentioned, but misguided in places. Fourth, what is the motivation of people who maintain their point of view despite the evidence? Sadly, the presentation of new empirical evidence polarizes, rather than reconciles, opinion. Too many have made a career out of either promoting or denigrating PGT-A for them to back down easily. Finally, how can we find common ground and move forward? All patients should be counselled in a non-directive manner on whether to embark on PGT-A, summarizing for them the whole evidence base so they can make up their own mind.
Griffiths, Alys Wyn; Surr, Claire A.; Creese, Byron; Garrod, Lucy; Chenoweth, Lynn	2019	The development and use of the assessment of dementia awareness and person-centred care training tool in long-term care	Dementia (London, England)	18	7-8	3059–3070	
Grimes, Jeffrey L.; Kivlighan III, D. Martin	2022	Whose multicultural orientation matters most? Examining additive and compensatory	Group Dynamics: Theory, Research, and Practice	26	1	58–70	Objective: The multicultural orientation (MCO) framework has received increased attention within the multicultural group work literature. However, most of this research has examined cultural processes between group members and how cultural processes of the group-as-a-whole directly impact outcomes of individual members. As such, the effect of group leaders' MCO on members'

		effects of the group's and leader's multicultural orientation in group therapy					improvement has largely been ignored. Understanding the complex interaction between leaders' and group members' MCO is critical to advance this body of literature and further understand the dynamic interplay of cultural processes between leaders and members of therapy groups. Method: Data for this study consisted of 101 group members across 48 interpersonal process groups at 12 university counseling centers. Polynomial regression and response surface analysis were conducted to test additive and compensatory effects between members' perceptions of their group's and their leaders' MCO on their perceived improvement in group therapy. Results: Clients' estimated improvement was highest when their perceptions of their group's and leaders' cultural humility were congruent and high (i.e., additive effect). Additionally, clients' estimated improvement was highest when clients perceived either (a) the group high in cultural missed opportunities and leaders low in cultural missed opportunities or (b) the group low in cultural missed opportunities and leaders high in cultural missed opportunities (i.e., compensatory effect). Conclusions: This article grows the existing body of literature on MCO orientation by exploring how group's and leaders' MCO interact in complex and important ways with client's perceived improvement in therapy. Both leaders and members should engage in cultural aspects of the group. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Griner, Derek; Erekson, David M.; Beecher, Mark E.; Cattani, Kara;	2022	The power of compassion in group psychotherapy	Journal of clinical psychology	78	8	1601–1612	Research has repeatedly demonstrated that individual and group psychotherapy are equally effective. Compassion-focused therapy (CFT) has been shown to be an effective approach to treating individuals with a wide range of presenting mental health concerns. In this

Burlingame, Gary M.							study, we discuss the basic tenets of CFT and introduce a 12-module CFT group psychotherapy approach for college counseling centers. We use a clinical vignette to provide an example of how psychotherapists may implement this approach. We then discuss clinical applications, including strengths and limitations of this approach.
Grobe, James E.; Goggin, Kathy; Harris, Kari Jo; Richter, Kimber P.; Resnicow, Ken; Catley, Delwyn	2020	Race moderates the effects of Motivational Interviewing on smoking cessation induction	Patient education and counseling	103	2	350–358	OBJECTIVE: Health disparities necessitate exploration of how race moderates response to smoking cessation treatment. Data from a randomized clinical trial of Motivational Interviewing (MI) for smoking cessation induction were used to explore differential treatment response between African American (AA) vs Non-Black (NB) smokers. METHODS: Adult tobacco smokers (138 AA vs 66 NB) with low desire to quit were randomly assigned to four sessions of MI or health education (HE). Outcomes (e.g., quit attempts) were assessed 3- and 6-months. RESULTS: There was evidence of a Race by Treatment interaction such that MI was less effective than HE in AA smokers. Mean Cohen's d for the interaction effect was -0.32 (95% CI [-0.44, -0.20]). However, the race interaction could be accounted for by controlling for baseline relationship status and communication preference (wants directive approach). CONCLUSIONS: MI may be less effective for smoking cessation induction in AA vs NB smokers when compared to another active and more directive therapy. The differential response between races may be explained by psychosocial variables. PRACTICE IMPLICATIONS: MI may not be an ideal choice for all African American smokers. Patients' relationship status and preference for a directive counseling approach might explain disparities in response to MI treatment.

Grochowiak, Klaus	2017	Sorge dich und lebe jetzt! Daseinsanalyse und NLP: Wie wir fr uns sorgen knnen, ohne die Katastrophe zu beschwren. Vorschlag zur Erweiterung des NLP-Curriculums	Praxis Kommunikation	3	2	62–65	Es wird ein Vorschlag zur Erweiterung des Neurolinguistischen Programmierens um Einsichten aus der Daseinsanalyse gemacht. Dabei wird als beste Methode, sich gut zu fhlen, ganz im Hier und Jetzt zu sein erachtet. Auch die angenehme Wirkung der Gedankenleere wird hervorgehoben. Schlielich wird der Unterschied zwischen Des-Identifikation und Dissoziation erlutert.
Groot, Marlies de; Laceulle, Odilia M.; Cissen, Helma; Tiemens, Bea; van der Heijden, Paul T.	2022	Symptom distress and disability: Different sides of the same coin? An investigation of the relationship between symptom distress and disability over time in patients receiving treatment for internalizing disorders	Journal of clinical psychology	78	12	2446–2455	BACKGROUND Most psychotherapy outcome research focuses on symptom reduction as a primary outcome. However, most patients do not seek psychological treatment exclusively for symptom relief, but mainly because they can no longer do what they want to do or used to do. Therefore, besides symptom reduction, also disability in daily functioning should be a focus of psychotherapy outcome research. Yet, until now there is a paucity in research pertaining to the relation between symptom reduction and reduction of disability during psychological treatment. AIMS For this reason, the aim of the current study was to examine the relationship between changes in symptom reduction (reduction in general symptom distress) and changes in self-reported disability over a period of two years in patients that receive psychotherapy for mood and anxiety disorders (N = 1182). RESULTS We found strong correlations between both outcome

							<p>measures at all measurement points. Furthermore, results demonstrated a decrease in both outcome measures from start to end of treatment with a moderate effect for symptom distress and a small effect for experienced disability. Cross-lagged panel analysis demonstrated that a decrease in symptom distress predicted a subsequent decrease in self-reported disability, and a decrease in self-reported disability equally predicted a subsequent decrease in experienced symptom distress.</p> <p>CONCLUSION</p> <p>Our results seem to indicate that both outcome measures are interchangeable in psychotherapy outcome studies for internalizing disorders.</p>
<p>grosse Holtforth, Martin; Krieger, Tobias; Zimmermann, Johannes; Altenstein-Yamanaka, David; Drig, Nadja; Meisch, Laurence; Hayes, Adele M.</p>	2019	<p>A randomized-controlled trial of cognitive-behavioral therapy for depression with integrated techniques from emotion-focused and exposure therapies</p>	<p>Psychotherapy Research</p>	29	1	30–44	<p>Background: Emotional processing (EP) is hypothesized to be a key mechanism of change in psychotherapy that may enhance its long-term efficacy. To study the effects of fostering EP in psychotherapy for depression, this randomized-controlled clinical trial compares the efficacy and pattern of change of a cognitive-behavioral therapy that integrates emotion-focused techniques within an exposure framework (Exposure-Based Cognitive Therapy for depression; EBCT-R) to a standard cognitive-behavioral therapy (CBT). Methods: One hundred and forty-nine depressed outpatients were randomized to a maximum of 22 sessions of manualized EBCT-R (N = 77) or CBT (N = 72). Primary outcomes were self-reported and clinician-rated depressive symptoms at posttreatment and 12-month follow-up. Secondary outcomes were self-esteem, interpersonal problems, and avoidance thoughts and behaviors. Results: Depressive symptoms improved significantly over therapy in both treatments, with large within-group effect sizes for CBT (d = -1.95) and EBCT-R (d</p>

							= -1.77). The pattern of depression change during treatment did not differ between treatments. Symptom relief lasted over 12 months and did not differ between EBCT-R and CBT. Conclusions: Results suggest that both treatments produced significant short- and long-term improvement in depression symptoms, but the integration of emotion-focused techniques within an exposure framework did not have added benefit.
Groth, Taylor; Hilsenroth, Mark	2021	Psychotherapy techniques related to therapist alliance among adolescents with eating disorders: The utility of integration	Journal of Psychotherapy Integration	31	1	104-114	This study is the 1st to explore specific therapeutic techniques clinicians find helpful in establishing and maintaining alliance with adolescents with eating disorders. Data was collected from 107 experienced therapists (Myears = 16) currently treating an eating-disordered adolescent. Therapists held degrees in various disciplines in mental health (MA, MS, MSW, MHC, PhD, PsyD) or in medicine (MD), who came from various theoretical orientations (cognitive-behavioral [CB] = 46.7%, psychodynamic = 13.1%, interpersonal = 13.1%, family = 7.5%, humanistic = 3.7%, and other = 15.9%). Therapists rated the utility of various psychodynamic-interpersonal, CB, and adjunctive eating disorder interventions, as well as their alliance with that patient. The majority of the patients (N = 107) reported on were female (n = 102) and diagnosed with anorexia (n = 70), bulimia (n = 14), binge eating (n = 9), or other specified feeding or eating disorders (n = 14). Therapists reported a constellation of integrative treatment interventions related to alliance. Specifically, a forward stepwise regression yielded a final, 7-step model predicting therapist alliance ($R = .704$, $r^2 = .495$), $F(102) = 4.599$, $p = .035$. The final regression model revealed specific items from each treatment approach to be significantly related to alliance, with the most important

							item being an in-session focus on the therapeutic relationship. Findings highlight how an integrative model of treatment interventions, with emphasis on the focus of the therapist–patient relationship in session, might be explored in future work to help facilitate the alliance in the treatment of adolescents with eating disorders. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Groth, Taylor; Hilsenroth, Mark J.; Gold, Jerold; Boccio, Dana; Tasca, Giorgio A.	2020	Therapist factors related to the treatment of adolescent eating disorders	Professional Psychology: Research and Practice		19 39- 13 23(Electronic), 07 35- 70 28(Print)	517–526	Eating disorders (EDs) are historically complex to treat, and evidence-based recommendations for treating adolescents with EDs need to be improved. The present study is unique and distinctive as it is the first to assess therapists’ report of their technique, working alliance, and countertransference with ED adolescents in relation to patient factors of childhood traumatic experiences as well as ED symptomatology. One hundred and four experienced (M = 16.28 years as clinician) therapists from a variety of different theoretical orientations and disciplines currently treating an adolescent patient diagnosed with an ED for at least 8 sessions completed an online survey. These therapists completed measures of therapists’ technique, alliance, and countertransference, as well as a DSM–5 ED symptom and childhood trauma questionnaire regarding their patients. Therapists reported experiencing more special/overinvolved countertransference when the patient had greater trauma severity, specifically with patients who experienced more severe traumatic parental upheavals and had been a victim of violence. In addition, therapists used more psychodynamic interpersonal (PI) techniques when treating patients with more severe trauma histories, especially when they were victim to a major parental upheaval, childhood sexual abuse, and serious injury. PI was also significantly related to total ED

							symptoms, and most specifically with bulimia nervosa and binge ED symptoms. Despite these findings, there was a lack of significance for therapist alliance with ED symptom or trauma variables. Overall, these findings highlight how therapist treatment process may be related to aspects of trauma history and symptomatology when treating an adolescent with an ED. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Grtz, Astrid	2016	Ein Therapie-Rckblick aus existenzanalytischer Sicht als Methode der qualitativen Psychotherapieforschung	Existenzanalyse	33	1	15–24	Am Beispiel einer existenzanalytischen Traumatherapie mit einer jungen Erwachsenen wird aufgezeigt, welche Erkenntnisse im Sinne der qualitativen Psychotherapieforschung aus einem gemeinsamen Rckblick in Form eines Dialogs zwischen Therapeut und Klient gewonnen werden knnen. Im Anschluss wird der Unterschied zum Change-Interview nach Elliott herausgearbeitet. Beide Formen der Gesprchsfhrung werden einander gegenberstellt, wobei das Original-Transkript in Auszgen wiedergegeben wird. Schlielich wird auf Aspekte der Forschungsethik eingegangen.
Grtz, Astrid	2019	"Was hat mir geholfen?" - Wirkelemente im Therapieprozess aus Patienten-Sicht. Ein Beitrag zur Psychotherapie-Prozessforschung	Existenzanalyse	36	1	15–43	Im vorliegenden Beitrag werden auf Basis von rckblickenden Gesprchen bzw. strukturierten Interviews die Wirkelemente von drei existenzanalytischen Psychotherapie-Prozessen bei unterschiedlichen Diagnosen mit Schwerpunkten in verschiedenen existentiellen Grundmotivationen analysiert. Zunchst wird auf grundlegende berlegungen zur Wirksamkeitsforschung in der Psychotherapie eingegangen. Im empirischen Hauptteil wird fr jeweils drei Patientinnen (21 Jahre, 34 Jahre, 42 Jahre) erst die Patientinnen-Sicht auf induktivem Weg analysiert. Fr das Verstdnis der Therapie-Wirkungen werden dann als theoretischer Rahmen die existentiellen Grundmotivationen und die Personale Existenzanalyse

						herangezogen. Schliesslich wird die Patientinnen-Aussage mithilfe einer hermeneutisch-phnomenologischen Analyse aus Therapeuten-Perspektive zu einer intersubjektiven Aussage hinsichtlich der Wirkelemente in der existenzanalytischen Psychotherapie verdichtet. Die fallbezogenen Erkenntnisse werden bei zwei Patientinnen mit quantitativen Selbsteinschätzungen in Beziehung gesetzt. Anhand dieser Fallvergleiche wird die therapeutische Arbeit mit der Personalen Existenzanalyse in Hinblick auf die klinischen Bilder theoretisch spezifiziert. Schliesslich resultieren daraus allgemeine berlegungen zu adquaten Forschungszugngen in der qualitativen Einzelfall- bzw. Prozessforschung.
Grzanka, Patrick R.; Zeiders, Katharine H.; Miles, Joseph R.	2016	Beyond “born this way?” reconsidering sexual orientation beliefs and attitudes	Journal of Counseling Psychology	63	1	Previous research on heterosexuals’ beliefs about sexual orientation (SO) has been limited in that it has generally examined heterosexuals’ beliefs from an essentialist perspective. The recently developed Sexual Orientation Beliefs Scale (SOBS; Arseneau, Grzanka, Miles, & Fassinger, 2013) assesses multifarious “lay beliefs” about SO from essentialist, social constructionist, and constructivist perspectives. This study used the SOBS to explore latent group-based patterns in endorsement of these beliefs in 2 samples of undergraduate students: a mixed-gender sample (n = 379) and an all-women sample (n = 266). While previous research has posited that essentialist beliefs about the innateness of SO predict positive attitudes toward sexual minorities, our research contributes to a growing body of scholarship that suggests that biological essentialism should be considered in the context of other beliefs. Using a person-centered analytic strategy, we found that that college students fell into distinct patterns of SO beliefs that are more different on beliefs about the homogeneity,

							discreteness, and informativeness of SO categories than on beliefs about the naturalness of SO. Individuals with higher levels of endorsement on all 4 SOBS subscales (a group we named multidimensional essentialism) and those who were highest in discreteness, homogeneity, and informativeness beliefs (i.e., high-DHI) reported higher levels of homonegativity when compared with those who were high only in naturalness beliefs. We discuss the implications of these findings for counseling and psychotherapy about SO, as well educational and social interventions. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Gu, Honglei; Fang, Lanlan; Yang, Cong	2023	Peer Victimization and Adolescent Non-Suicidal Self-Injury: The Mediating Role of Alienation and Moderating Role of Mindfulness	Journal of interpersonal violence	38	3-4	3864– 3882	Peer victimization and non-suicidal self-injury (NSSI) are two major public health problems, with the former being associated with outward attack and the latter characterizing inward attack. Peer victimization has been shown to be associated with adolescents' NSSI. However, less is known about the mechanism underlying the association. Based on the experiential avoidance model of NSSI, this study tested whether the sense of alienation mediated the association between peer victimization and NSSI, and whether this process was weakened by mindfulness. A total of 1,574 Chinese adolescents (51.1% girls; ages 12-16 years) completed questionnaires concerning NSSI, peer victimization, alienation, and mindfulness. Regression-based analyses indicated that peer victimization predicted adolescents' NSSI through the indirect effect of alienation, and mindfulness weakened this indirect effect. These findings suggest that victimized adolescents may injure themselves as an emotion regulation strategy. The results highlight the importance to implement programs aimed to improve the school climate to reduce the risk of adolescent NSSI.

							Furthermore, we underscore the need to include emotion-regulation training (e.g., mindful practice) into bully intervention programs to prevent NSSI.
Gudaitė, Gražina	2019	Psychotherapy research: an interplay between inner and outer and a succession of meanings	The Journal of analytical psychology	64	4	512–529	Psychotherapy research is a rapidly developing area of study that aims to explore the integration of inner and outer conditions of an individual's experience, the interplay between subjective and objective, as well as between individual and collective. Questions regarding a more integrative view and qualitative research in psychotherapy are discussed in the paper. The author introduces some ideas from the studies on psychotherapy effectiveness that were done at Vilnius University by a group of researchers who work in the 'Centre for research on the psychodynamics of personality'. Clinical psychologists who hold a doctorate degree or who are in doctoral studies in the Department of Psychology at Vilnius University are members of this research group. The subjective understanding about healing episodes and the development of depth premises were the main tasks of these studies. Among other methods, the researchers used the drawing a picture of a healing moment and telling a psychotherapy story recalled by the client to collect data. Two examples of drawing a picture of a healing moment and one example of telling a therapy story are analyzed in the paper. The themes of subjective experience of renewal in psychotherapy as well as the multiplicity of experience and results in psychotherapy are discussed in the paper with case illustrations. This study showed that drawing a picture opens one more dimension of reflection and that it can be an appropriate tool for developing individual narratives as well. Authoring and re-authoring one's life narrative is accepted as part of a productive therapy as

						<p>well as discovering one's inner authorship. The ability to follow a succession of meanings, as well as a connection to nature and culture could be one of the ways of actualizing an integrative view in psychotherapy research. La recherche dans le domaine de la psychothérapie est un domaine d'étude en croissance rapide qui vise à étudier l'intégration des conditions intérieures et extérieures dans l'expérience d'une personne, l'interaction entre le subjectif et l'objectif, ainsi qu'entre l'individuel et le collectif. L'article aborde des questions concernant une perspective plus intégrative et la recherche qualitative en psychothérapie. L'auteur introduit des idées provenant d'études faites par un groupe de chercheurs à l'université de Vilnius sur l'efficacité de la psychothérapie. Ces chercheurs travaillent au « Centre for research on the psychodynamics of personality » (Centre de recherche sur les psychodynamiques de la personnalité). Ils sont docteurs en psychologie clinique ou doctorants dans le département de Psychologie à l'université de Vilnius. L'objet principal de ces recherches est la compréhension subjective d'épisodes de guérison et la construction de postulats de profondeur. Parmi différentes méthodes pour obtenir des données, les chercheurs ont utilisé celle consistant à faire un dessin d'un moment de guérison et celle consistant à raconter une histoire de psychothérapie telle que le client se la rappelle. Deux exemples de faire un dessin d'un moment de guérison ainsi qu'un exemple de raconter une histoire de psychothérapie sont analysés dans l'article. Les thèmes de l'expérience subjective du renouveau en psychothérapie, ainsi que la multiplicité d'expérience et de résultats en psychothérapie sont traités dans l'article</p>
--	--	--	--	--	--	---

						<p>et illustrés par des cas. Cette étude montre que de faire un dessin ouvre une dimension de plus dans la réflexion et que cela peut être un outil approprié pour le développement des récits individuels. Être l'auteur de son récit de vie, ainsi que de sa réécriture, est considéré comme étant un aspect d'une thérapie productive. De même que découvrir sa capacité intérieure à « être auteur ». La capacité à suivre une succession de significations, ainsi qu'un lien avec la nature et la culture pourraient être une des manières d'actualiser une perspective intégrative dans la recherche en psychothérapie.</p> <p>Psychotherapieforschung ist ein sich rasant entwickelndes Forschungsgebiet, das darauf abzielt, die Integration der inneren und äußeren Bedingungen einer individuellen Erfahrung, das Zusammenspiel von Subjektivem und Objektivem sowie von Individuellem und Kollektivem zu untersuchen. In diesem Beitrag werden Fragen diskutiert, die sowohl eine integrativere Sichtweise als auch qualitative Forschung in der Psychotherapie berücksichtigen. Die Autorin stellt einige Ideen aus Studien zur Wirksamkeit von Psychotherapie vor, die an der Universität Vilnius von einer Gruppe von Forschern durchgeführt wurden, die im 'Zentrum zur Erforschung der Psychodynamik der Persönlichkeit' arbeiten. Zu dieser Forschergruppe gehören promovierte klinische Psychologen oder solche, die gegenwärtig am Institut für Psychologie der Universität Vilnius promovieren. Das subjektive Verständnis von Heilungsepisoden und die Entwicklung von Tiefenprämissen stellten die Hauptthemen dieser Studien dar. Neben anderen Methoden verwendeten die Forscher das Zeichnen eines Bildes eines Heilungsmomentes und das Erzählen einer Psychotherapiegeschichte, wie sie von Klienten erinnert</p>
--	--	--	--	--	--	--

						<p>wurde, um Daten zu sammeln. In der Arbeit werden zwei Beispiele für das Zeichnen eines Bildes eines Heilungsmomentes und ein Beispiel für das Erzählen einer Therapiegeschichte analysiert. Anhand von Falldarstellungen werden in dem Beitrag die Themen der subjektiven Erfahrung von Erneuerung in der Psychotherapie und die Vielzahl der Erfahrungen mit sowie die Ergebnisse von Psychotherapie diskutiert. Diese Studie hat gezeigt, daß das Zeichnen eines Bildes eine weitere Dimension der Reflexion eröffnet und ein geeignetes Werkzeug für die Entwicklung individueller Erzählungen sein kann. Das Verfassen und Neuverfassen der eigenen Lebenserzählung wird dabei als Teil einer produktiven Therapie und als Entdeckung der inneren Urheberschaft angesehen. Die Fähigkeit, einer Sukzession von Bedeutungen zu folgen sowie eine Verbindung zu Natur und Kultur herzustellen könnte eine der Möglichkeiten sein, eine integrative Sichtweise in der Psychotherapieforschung zu verwirklichen.</p> <p>La ricerca in psicoterapia è un'area di studio in rapida evoluzione che tende ad esplorare l'integrazione tra le condizioni interne ed esterne dell'esperienza individuale, l'interazione tra soggettivo ed oggettivo tanto quanto tra individuale e collettivo. Nell'articolo vengono affrontate domande relative ad una visione più integrativa ed alla ricerca qualitativa in psicoterapia. L'Autrice introduce alcune idee prese dagli studi sull'efficacia della psicoterapia effettuati all'università di Vilnius da un gruppo di ricercatori, che lavorano nel 'Center for Research on the psychodynamics of personality'.</p> <p>Psicologi clinici che hanno conseguito un dottorato o che lo stanno per conseguire presso il Dipartimento di Psicologia dell'Università di Vilnius fanno parte di questo</p>

Guerrero, Mayra; Longan, Casey; Cummings, Camilla; Kassanits, Jessica; Reilly, Angela; Stevens, Ed; Jason, Leonard A.	2022	Women's friendships: A basis for individual-level resources and their connection to power and optimism	The Humanistic Psychologist		15 47- 33 33(Ele ctr oni c), 08 87- 32 67(Pri nt)	360-375	The study examined how friendships among women in recovery from substance use disorders are related to individual resources (e.g., social support, self-esteem, and hope) and empowerment (e.g., power and optimism). Findings from a path analysis of 244 women in recovery revealed that friendships among women were positively related to individual resources; that is, the stronger the relationships with other women, the higher women perceived their resources to be. Further, individual-level resources mediated the relations between friendships and empowerment, with higher levels of individual resources related to higher levels of empowerment constructs of power and optimism. Results point to the importance of developing and sustaining empowering relationships for women in recovery. Findings have implications for gender-specific treatment practices and recommendations impacting substance use recovery outcomes. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Guerrini Usubini, Anna; Cattivelli, Roberto; Bertuzzi, Vanessa; Varallo, Giorgia; Rossi, Alessandro Alberto; Volpi, Clarissa; Bottacchi, Michela; Tamini, Sofia; Col,	2021	The ACTyourCHANGE in Teens Study Protocol: An Acceptance and Commitment Therapy-Based Intervention for Adolescents with Obesity: A Randomized Controlled Trial	International journal of environmental research and public health	18	12		This Randomized Controlled Trial [(RCT) aims to evaluate the effectiveness of a brief Acceptance and Commitment Therapy (ACT)-based intervention combined with treatment as usual (TAU) compared to TAU only in improving psychological conditions in a sample of adolescents with obesity (body mass index, BMI > 97th percentile for age and sex) within the context of a wider multidisciplinary rehabilitation program for weight loss. Fifty consecutive adolescents (12-17 years) of both genders with obesity will be recruited among the patients hospitalized in a clinical center for obesity rehabilitation and randomly allocated into two experimental conditions: ACT + TAU vs. TAU only. Both groups will attend a three-week in-hospital multidisciplinary rehabilitation program

Alessandra de; Pietrabissa, Giada; Mannarini, Stefania; Castelnovo, Gianluca; Molinari, Enrico; Sartorio, Alessandro							for weight loss. The ACT + TAU condition comprises a psychological intervention based on ACT combined with a standard psychological assessment and support to the hospitalization. The TAU comprises the standard psychological assessment and support to the hospitalization. At pre- to post-psychological intervention, participants will complete the Avoidance and Fusion Questionnaire for Youth, the Psychological Well-Being Scale, the Depression Anxiety Stress Scale, the Difficulties in Emotion Regulation Scale, and the Emotional Eating subscale of the Dutch Eating Behavior Questionnaire to assess psychological well-being as the primary outcome and experiential avoidance, psychological distress, emotional dysregulation, and emotional eating as secondary outcomes. Repeated-measures ANOVAs (2 × 2) will be conducted. The study will assess the effectiveness of a brief ACT-based intervention for adolescents with obesity in improving their psychological conditions by targeting specific core processes of the ACT framework (openness, awareness, and engagement). Future directions of the study will assess whether these psychological processes will contribute to addressing long-term weight loss.
Guessoum, Sélim Benjamin; Minassian, Sevan; Staël, Pauline de; Touhami, Fatima; DiGiovanni, Madeline; Radjack,	2022	Multimodal co-therapy for unaccompanied minors: a qualitative study	Child and adolescent psychiatry and mental health	16	1	81	BACKGROUND: Unaccompanied refugee minors-or unaccompanied minors-are children and adolescents who have been separated from parents and other relatives and are not being cared for by an adult. Unaccompanied minors are a vulnerable population, with numerous stressors and complex psychiatric symptoms necessitating specialized mental health care. This study explores patients' experiences of a Multimodal Co-Therapy for Unaccompanied Minors (MUCTUM), which encompasses cultural, biological, narrative & institutional

Rahmeth; Moro, Marie Rose; Benoit, Laelia							<p>approaches to care. METHODS: MUCTUM is a co-therapy program for unaccompanied minors, with a psychiatrist, psychologist, native-language interpreter, and caseworker for each patient. In this qualitative study, we interviewed adolescents about their experiences with MUCTUM and analyzed these semi-structured interviews using a phenomenological framework (Interpretative Phenomenological Analysis). RESULTS: Qualitative analysis of 16 interviews discovered that unaccompanied minors felt misunderstood before participating in MUCTUM, describing a sense of strangeness and loneliness in relation to psychiatric symptoms. Several youths experienced triple stigmatization: of being unaccompanied minors, of suffering from psychotrauma, and of being mental health patients. We further describe three overarching domains that inform on MUCTUM support to unaccompanied minors: (1) A safe space for unaccompanied minors; (2) Helpful interventions during therapy; and (3) Narrating one's story can "set us free" if guided carefully by care providers. CONCLUSION: This study suggests that MUCTUM therapy may efficiently support unaccompanied minors' mental health by acknowledging their hierarchy of needs.</p> <p>Psychotherapeutic strategies include creating a safe place, providing culturally appropriate care and patient-centered therapy, addressing concrete problems, supporting relationships, and making use of limited reparenting in therapy. Delayed and progressive inquiry about traumatic events may be beneficial. Replication of these findings and their field application is warranted.</p>
Guiffrida, Douglas A.; McGuinness,	2023	A qualitative study of clients with chronic	Journal of Psychotherapy Integration		15 73- 36	No Paginatio n	The purpose of this qualitative study was to understand the experiences of 11 clients with chronic pain who participated in a 10-week, small group psychotherapy

Scott; Carter, Rachel; Miller, Daniel; Farah, Jennifer		pain who participated in an integrative mind/body psychotherapy intervention			96(Electronic), 1053-0479(Print)	Specified -No Pageination Specified	intervention that integrated emotional awareness and expression therapy and mindfulness. Qualitative interviews using constructivist grounded theory were conducted with participants to understand their experiences. The findings identify a set of conditions under which the approach is perceived as effective in alleviating chronic pain, as well as conditions under which participants perceived moderate or no benefit from the intervention. These findings provide the potential to inform future treatment protocols and interventions. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Gultekin, Murat; Ekinici, Ayten; Erturk, Gozde; Mirza, Meral	2017	Female Parkinson's disease caregivers have much anxiety and depressive symptom	Brain and behavior	7	9	e00787	<p>OBJECTIVE Parkinson's Disease Caregivers (PDC) play an important role, especially in the medium and advanced phase of the disease for patients' daily life activities, treatment, and follow-up. The aim of this study is to attract attention to the factors which place PDC at risk of psychological problems and to give consideration to these factors.</p> <p>MATERIALS AND METHODS First of all, the 80 participants, who were PDC, filled in the demographic information form. The Hospital Anxiety and Depression Scale (HADS) was applied in order to determine the psychological status of the PDC.</p> <p>RESULTS The average age of PDC in the study was found as 47.94. While 11 (13.8%) of the PDC had undergone psychiatric treatment in the past, four of them (5%) were currently receiving treatment. Twenty-eight (35%) of those who provide care have experience in patient care, whereas 52 (65%) of them have no prior experience in caring for patients. Thirty-six (45%) of the PDC reported that they had difficulties, which were mostly psychological.</p>

							<p>According to the HADS which was applied, anxiety was seen in 26 of those who provide care (32.5%), while depression was seen in 41 (51.3%).</p> <p>CONCLUSION</p> <p>This study is the first to provide data on the psychological status of PDC in our country. It is important that PDC's psychological problems are reduced by psychotherapy or, if necessary, by treatment. This situation has a direct negative effect on the patient's daily life activities.</p>
Gülüm, I. Volkan; Soygüt, Gonca	2022	Limited reparenting as a corrective emotional experience in schema therapy: A preliminary task analysis	Psychotherapy research : journal of the Society for Psychotherapy Research	32	2	263–276	<p>AIM: To construct a process model of limited reparenting as a corrective emotional experience using schema therapy (ST). METHOD: We followed a task analytical approach, building two separate rational models based on the ST theory and our experience. Then, we constructed a final rational model. We tested our model in five therapy sessions. RESULTS: The process began with noticing a schema activation, after which a complex, interwoven process occurred involving facilitation and validation of the client's experiences, exploration of schema origins, engaging the client's process, and responding to unmet needs within professional boundaries. The limited reparenting experience in ST involves the use of psychotherapeutic techniques and, crucially, how these techniques are used in line with the ST model deployed. CONCLUSION: Our results provided a roadmap and clarified the important aspects of limited reparenting. Providing clients with healthy and potentially corrective emotional experiences, facilitating and validating the feelings, understanding schema origins, and being willing to provide limited reparenting are the key features of the ST. It is more important to comprehend the philosophy behind ST than to focus on the specific</p>

							(cognitive, behavioral, interpersonal, experiential, etc.) techniques.
Gundel, Brittany E.; Bartholomew, Theodore T.; Scheel, Michael J.	2020	Culture and care: An illustration of multicultural processes in a counseling dyad	Practice Innovations	5	1		Attention to cultural factors in counseling is critical, and theories have emerged in counseling and psychology to describe competence for working with multicultural clients. Among the emergent theoretical considerations is the multicultural orientation perspective, which prioritizes therapists' emphasis on cultural humility, attendance to cultural opportunities, and cultural comfort within sessions. To better understand the manifestation of multicultural processes in psychotherapy, we used an instrumental case study design to independently interview a counselor and client who were working together. The client and therapist were culturally different from one another in salient aspects of identity, and the interview focused on their respective experiences of multicultural processes in sessions. Data were analyzed using Stake's (2006) case study approach. Analysis resulted in the identification of three themes: (a) open exploration of culture, (b) integration of salient cultural factors, and (c) expectation of addressing culture. Findings are discussed with respect to the role of culture in counseling and the emergence of multicultural orientation. (PsycINFO Database Record (c) 2020 APA, all rights reserved)
Gunlicks-Stoessel, Meredith; Mufson, Laura	2016	Innovations in Practice: a pilot study of interpersonal psychotherapy for depressed adolescents	Child Adolesc Ment Health (Child and Adolescent Mental Health)	21	4	225-230	Background Problems in adolescents? relationships with their parents are a significant risk factor for the development and maintenance of depression. The purpose of this pilot study was to examine the feasibility and acceptability of an adaptation of interpersonal psychotherapy for depressed adolescents (IPT-A) who were also experiencing problems in their relationships with parents. The adaptation includes greater and more

		and their parents					structured parent involvement in the treatment (IPT-AP). Method Fifteen adolescents (age 12-17) who were diagnosed with depression and were also experiencing conflictual or emotionally disengaged relationships with their parents (based on adolescent or parent report on the Conflict Behavior Questionnaire) participated in a 16 week randomized clinical trial of individually delivered IPT-A versus IPT-AP. Data regarding the feasibility and acceptability of IPT-AP were collected. Assessments of depression and family functioning were completed at baseline and weeks 4, 8, 12, and 16 by evaluators blind to treatment condition. Results IPT-AP was feasible to implement, and adolescents and parents reported high treatment satisfaction. Adolescents demonstrated significant improvements in depressive symptoms, general functioning, and family functioning. IPT-AP was more efficacious than individual IPT-A in improving adolescents' perceptions of father-adolescent relations and mothers' perceptions of mother-adolescent relations. Conclusions Interpersonal psychotherapy for depressed adolescents and their parents was feasible to implement and acceptable to families, indicating that a full-scale randomized controlled trial to evaluate its efficacy is warranted.
Gunst, Ellen; Watson, Jeanne; Willemsen, Jochem; Desmet, Mattias; Loeys, Tom; Vanhooren, Siebrecht	2020	A quest for self-soothing: A systematic case study into emotion-focused therapy with an emotionally avoidant client	Journal of clinical psychology	76	4	676-687	The current study is part of a multiple case study that investigated the emotional change in individuals who have committed sexual offenses (ISOs). This case study highlights how one client used sex as a maladaptive coping strategy to suppress negative emotions. A mixed-methods design was used to track changes in the client's affect regulation (AR) during four phases, including a baseline (Phase A), treatment as usual (Phase B), treatment with an emotion-focused therapy (EFT)

		who committed sexual offenses					component added (Phase C), and follow up (Phase A). The qualitative description with verbatim clinical vignettes, revealed deeper insight into some important steps and hindrances and the impact of specific EFT-interventions. Quantitative analysis of self-report and observational measures showed a significant improvement in the client's AR across different phases of treatment. The study improves our knowledge of the emotional change in ISOs during treatment and illustrates some key interventions, steps, and hindrances. 2019 Wiley Periodicals, Inc.
Günther, Fritz; Dudschig, Carolin; Kaup, Barbara	2018	Symbol Grounding Without Direct Experience: Do Words Inherit Sensorimotor Activation From Purely Linguistic Context?	Cognitive science	42 Suppl 2		336–374	Theories of embodied cognition assume that concepts are grounded in non-linguistic, sensorimotor experience. In support of this assumption, previous studies have shown that upwards response movements are faster than downwards movements after participants have been presented with words whose referents are typically located in the upper vertical space (and vice versa for downwards responses). This is taken as evidence that processing these words reactivates sensorimotor experiential traces. This congruency effect was also found for novel words, after participants learned these words as labels for novel objects that they encountered either in their upper or lower visual field. While this indicates that direct experience with a word's referent is sufficient to evoke said congruency effects, the present study investigates whether this direct experience is also a necessary condition. To this end, we conducted five experiments in which participants learned novel words from purely linguistic input: Novel words were presented in pairs with real up- or down-words (Experiment 1); they were presented in natural sentences where they replaced these real words (Experiment 2); they were presented as

							<p>new labels for these real words (Experiment 3); and they were presented as labels for novel combined concepts based on these real words (Experiment 4 and 5). In all five experiments, we did not find any congruency effects elicited by the novel words; however, participants were always able to make correct explicit judgements about the vertical dimension associated to the novel words. These results suggest that direct experience is necessary for reactivating experiential traces, but this reactivation is not a necessary condition for understanding (in the sense of storing and accessing) the corresponding aspects of word meaning.</p>
Gupta, Nihit; Chaudhary, Ridhima; Gupta, Mayank; Ikehara, Linh-Han; Zubiar, Faiza; Madabushi, Jayakrishna S.	2023	Play Therapy As Effective Options for School-Age Children With Emotional and Behavioral Problems: A Case Series	Cureus	15	6	e40093	<p>As a type of psychotherapy, play therapy entails using play and creative activities as a means to help children express their thoughts and emotions, and to work through their challenges. A wide range of issues can be addressed through play therapy, including behavioral issues, anxiety, depression, trauma, and difficulties in relationships. Through this case report, we aim to discuss the history and evolution of play therapy concepts. We will review the core principles of child-centered therapy (CCT), non-directive child-centered play (NDCCP), and cognitive behavior play therapy. We will discuss clinically helpful approaches and the evidence supporting the efficacy of play therapy in anxiety, depression, trauma, and other behavioral difficulties in children.</p>
Gutierrez, Peter M.; Johnson, Lora; Podlogar, Matthew C.; Hagman, Stacy; Muehler, Tanner A.; Hanson,	2022	Pilot study of the Collaborative Assessment and Management of	Suicide & life-threatening behavior	52	2	244–255	<p>INTRODUCTION</p> <p>Few evidence-based options exist for outpatient treatment of patients at risk of suicide, and to-date almost all research has focused on individually delivered psychotherapy. Group therapy for veterans at risk of suicide is a promising alternative.</p> <p>METHODS</p>

<p>Jetta; Pierson, Jonathan T.; Brown, Austin A.; O'Connor, Stephen</p>		<p>Suicidality-Group</p>					<p>Thirty veterans receiving care at an urban Veterans Affairs Medical Center in the southern United States were randomized to either care as usual (CAU) or to CAU plus the Collaborative Assessment and Management of Suicide-Group (CAMS-G). Veterans were assessed prior to randomization to condition and at 1, 3, and 6 months post-randomization on a range of suicide-specific measures, burdensomeness, belonging, treatment satisfaction, and group cohesion.</p> <p>RESULTS</p> <p>Across measures and follow-up assessments, veterans in CAMS-G reported good satisfaction with the intervention, a sense of cohesion with other members of the group, and reduced symptom distress. Veterans in both conditions reported decreases in suicidal ideation and behavior, with CAMS-G participants potentially improving slightly faster.</p> <p>CONCLUSION</p> <p>This description of CAMS-G for veterans adds to the growing literature on suicide-specific interventions and supports the need for additional research to determine if wide-spread rollout is justifiable.</p>
<p>Guttman, Leah E.</p>	<p>2020</p>	<p>Disclosure and felt security in clinical supervision</p>	<p>Journal of Psychotherapy Integration</p>		<p>15 73- 36 96(</p>	<p>67-75</p>	<p>The empirical basis for understanding disclosure in clinical supervision is limited. Research has indicated that a majority of psychology trainees engage in concealment or distortion of clinical and nonclinical material despite expectations of transparency. This article explores the risks and benefits of disclosure by examining two experiences from my doctoral training. In Case Illustration 1, I describe working with a teenage boy, with a history of caregiver abandonment, and disclosing to my supervisor a desire to shift the therapeutic approach. I examine how my disclosure impacted our supervisory</p>

					79(Pri nt)		alliance and the patient's treatment outcome. In Case Illustration 2, I describe how a supervisor's personal disclosure facilitated my understanding of countertransference and intersubjectivity. I conclude by offering suggestions on how disclosure can strengthen alliance and felt security in supervision. (PsycINFO Database Record (c) 2020 APA, all rights reserved)
Gysin-Maillart, Anja; Schwab, Simon; Soravia, Leila; Megert, Millie; Michel, Konrad	2016	A Novel Brief Therapy for Patients Who Attempt Suicide: A 24-months Follow-Up Randomized Controlled Study of the Attempted Suicide Short Intervention Program (ASSIP)	PLoS medicine	13	3	e1001968	<p>BACKGROUND</p> <p>Attempted suicide is the main risk factor for suicide and repeated suicide attempts. However, the evidence for follow-up treatments reducing suicidal behavior in these patients is limited. The objective of the present study was to evaluate the efficacy of the Attempted Suicide Short Intervention Program (ASSIP) in reducing suicidal behavior. ASSIP is a novel brief therapy based on a patient-centered model of suicidal behavior, with an emphasis on early therapeutic alliance.</p> <p>METHODS AND FINDINGS</p> <p>Patients who had recently attempted suicide were randomly allocated to treatment as usual (n = 60) or treatment as usual plus ASSIP (n = 60). ASSIP participants received three therapy sessions followed by regular contact through personalized letters over 24 months. Participants considered to be at high risk of suicide were included, 63% were diagnosed with an affective disorder, and 50% had a history of prior suicide attempts. Clinical exclusion criteria were habitual self-harm, serious cognitive impairment, and psychotic disorder. Study participants completed a set of psychosocial and clinical questionnaires every 6 months over a 24-month follow-up period. The study represents a real-world clinical setting at an outpatient clinic of a university hospital of psychiatry. The primary outcome measure was repeat</p>

						<p>suicide attempts during the 24-month follow-up period. Secondary outcome measures were suicidal ideation, depression, and health-care utilization. Furthermore, effects of prior suicide attempts, depression at baseline, diagnosis, and therapeutic alliance on outcome were investigated. During the 24-month follow-up period, five repeat suicide attempts were recorded in the ASSIP group and 41 attempts in the control group. The rates of participants reattempting suicide at least once were 8.3% (n = 5) and 26.7% (n = 16). ASSIP was associated with an approximately 80% reduced risk of participants making at least one repeat suicide attempt (Wald $\chi^2_1 = 13.1$, 95% CI 12.4-13.7, $p < 0.001$). ASSIP participants spent 72% fewer days in the hospital during follow-up (ASSIP: 29 d; control group: 105 d; $W = 94.5$, $p = 0.038$). Higher scores of patient-rated therapeutic alliance in the ASSIP group were associated with a lower rate of repeat suicide attempts. Prior suicide attempts, depression, and a diagnosis of personality disorder at baseline did not significantly affect outcome. Participants with a diagnosis of borderline personality disorder (n = 20) had more previous suicide attempts and a higher number of reattempts. Key study limitations were missing data and dropout rates. Although both were generally low, they increased during follow-up. At 24 months, the group difference in dropout rate was significant: ASSIP, 7% (n = 4); control, 22% (n = 13). A further limitation is that we do not have detailed information of the co-active follow-up treatment apart from participant self-reports every 6 months on the setting and the duration of the co-active treatment.</p> <p>CONCLUSIONS</p> <p>ASSIP, a manual-based brief therapy for patients who have recently attempted suicide, administered in addition</p>
--	--	--	--	--	--	--

						<p>to the usual clinical treatment, was efficacious in reducing suicidal behavior in a real-world clinical setting. ASSIP fulfills the need for an easy-to-administer low-cost intervention. Large pragmatic trials will be needed to conclusively establish the efficacy of ASSIP and replicate our findings in other clinical settings.</p> <p>TRIAL REGISTRATION ClinicalTrials.gov NCT02505373.</p>
Ha, Jiyeon; Park, Yeon-Hwan	2020	Effects of a Person-Centered Nursing Intervention for Frailty among Prefrail Community-Dwelling Older Adults	International journal of environmental research and public health	17	18	<p>This study examined the effects of a person-centered nursing intervention program for frailty (PNIF) targeting community-dwelling prefrail older people in South Korea. The study participants were 40 community-dwelling older adults (≥ 65 years) who were classified as prefrail on the Cardiovascular Health Study (CHS) frailty index. The intervention group ($n = 20$) received group intervention sessions two days/week for twelve weeks and the control group ($n = 20$) attended lectures about frailty prevention one day/week for four weeks. The evaluation instruments included the CHS Frailty Index, a JAMAR^(®) hydraulic hand dynamometer, the Short Physical Performance Battery (SPPB), the Korean version of the Community Healthy Activities Model Program for Seniors Questionnaire (K-CHAMPS), the Mini Nutritional Assessment (MNA), the Geriatric Depression Scale Short Form-Korea Version (GDSSF-K), the ENRICH Social Support Instrument (ESSI), and the Goal Attainment Scale (GAS). Significant differences were found in the CHS Frailty Index ($p < 0.001$), left-hand grip strength ($p = 0.022$), right-hand grip strength ($p = 0.009$), SPPB ($p = 0.007$), K-CHAMPS ($p = 0.009$), MNA ($p = 0.018$), and GDSSF-K ($p = 0.001$) between the two groups after 12 weeks. No significant between-group differences in ESSI scores were observed. The PNIF effectively improved grip strength, physical</p>

							function, physical activity, and nutritional status, reduced depression, and prevented frailty among community-dwelling older adults.
Haagen, Joris F. G.; van Rijn, Allison; Knipscheer, Jeroen W.; van der Aa, Niels; Kleber, Rolf J.	2018	The dissociative post-traumatic stress disorder (PTSD) subtype: A treatment outcome cohort study in veterans with PTSD	The British journal of clinical psychology	57	2	203–222	<p>OBJECTIVES</p> <p>Dissociation is a prevalent phenomenon among veterans with post-traumatic stress disorder (PTSD) that may interfere with the effectiveness of treatment. This study aimed to replicate findings of a dissociative PTSD subtype, to identify corresponding patterns in coping style, symptom type, and symptom severity, and to investigate its impact on post-traumatic symptom improvement.</p> <p>METHODS</p> <p>Latent profile analysis (LPA) was applied to baseline data from 330 predominantly (97%) male treatment-seeking veterans (mean age 39.5 years) with a probable PTSD. Multinomial logistic models were used to identify predictors of dissociative PTSD. Eighty veterans with PTSD that commenced with psychotherapy were invited for a follow-up measure after 6 months. The majority (n = 64, 80% response rate) completed the follow-up measure. Changes in post-traumatic stress between baseline and follow-up were explored as a continuous distal outcome.</p> <p>RESULTS</p> <p>Latent profile analysis revealed four distinct patient profiles: 'low' (12.9%), 'moderate' (33.2%), 'severe' (45.1%), and 'dissociative' (8.8%) PTSD. The dissociative PTSD profile was characterized by more severe pathology levels, though not post-traumatic reactions symptom severity. Veterans with dissociative PTSD benefitted equally from PTSD treatment as veterans with non-dissociative PTSD with similar symptom severity.</p> <p>CONCLUSIONS</p>

							<p>Within a sample of veterans with PTSD, a subsample of severely dissociative veterans was identified, characterized by elevated severity levels on pathology dimensions. The dissociative PTSD subtype did not negatively impact PTSD treatment.</p> <p>PRACTITIONER POINTS</p> <p>The present findings confirmed the existence of a distinct subgroup veterans that fit the description of dissociative PTSD. Patients with dissociative PTSD subtype symptoms uniquely differed from patients with non-dissociative PTSD in the severity of several psychopathology dimensions. Dissociative and non-dissociative PTSD patients with similar post-traumatic severity levels showed similar levels of improvement after PTSD treatment. The observational design and small sample size caution interpretation of the treatment outcome data. The IES-R questionnaire does not assess all PTSD DSM-IV diagnostic criteria (14 of 17), although it is considered a valid measure for an indication of PTSD.</p>
Haberman, Ann; Shahar, Ben; Bar-Kalifa, Eran; Zilcha-Mano, Sigal; Diamond, Gary M.	2019	Exploring the process of change in emotion-focused therapy for social anxiety	Psychotherapy research: journal of the Society for Psychotherapy Research	29	7	908–918	<p>Objective: This study examined purported change mechanisms in emotion-focused therapy for social anxiety disorder. Methods: The sample included nine clients who had participated in a multiple-baseline case study trial examining the efficacy of emotion-focused therapy for social anxiety disorder (SAD). Multilevel analyses were conducted to examine the trajectories of emotions over the course of treatment, and whether primary adaptive emotions in a given session predicted levels of SAD symptoms, self-criticism, and self-reassurance over the course of the following week. Results: Findings showed a significant decrease in shame, and a marginally significant increase in assertive anger, over the course of treatment. Adaptive</p>

						<p>sadness/grief in a given session predicted less fear of negative evaluation over the course of the following week. Shame in a given session predicted higher levels of inadequate-self over the course of the following week. Finally, shame, and to a lesser degree assertive anger, in a given session predicted reassurance of self over the course of the following week. Neither assertive anger nor adaptive sadness/grief in a given session predicted levels of self-criticism over the course of the following week. Conclusions: These findings lend partial preliminary support for the therapeutic role of evoking and processing adaptive sadness/grief and assertive anger in the treatment of SAD.</p>
<p>Hack, Samantha M.; Medoff, Deborah R.; Brown, Clayton H.; Fang, Lijuan; Dixon, Lisa B.; Klingaman, Elizabeth A.; Park, Stephanie G.; Kreyenbuhl, Julie A.</p>	2016	<p>Predictors of patient communication in psychiatric medication encounters among veterans with serious mental illnesses</p>	<p>Psychiatric Rehabilitation Journal</p>	39	2	<p>Objective: Person-centered psychiatric services rely on consumers actively sharing personal information, opinions, and preferences with their providers. This research examined predictors of consumer communication during appointments for psychiatric medication prescriptions. Methods: The Roter Interaction Analysis System was used to code recorded Veterans Affairs psychiatric appointments with 175 consumers and 21 psychiatric medication prescribers and categorize communication by purpose: biomedical, psychosocial, facilitation, or rapport-building. Results: Regression analyses found that greater provider communication, symptomology, orientation to psychiatric recovery, and functioning on the Repeatable Battery for the Assessment of Neuropsychological Status Attention and Language indices, as well as consumer diagnostic label, were positive predictors of consumer communication, though the types of communication impacted varied. Conclusions and Implications for Practice: Provider communication is the easiest variable to intervene on to</p>

							create changes in consumer communication. Future research should also consider how cognitive and symptom factors may impact specific types of consumer communication in order to identify subgroups for targeted interventions. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Hadash, Yuval; Plonsker, Reut; Vago, David R.; Bernstein, Amit	2016	Experiential self-referential and selfless processing in mindfulness and mental health: Conceptual model and implicit measurement methodology	Psychological Assessment	28	7	856–869	We propose that Experiential Self-Referential Processing (ESRP)-the cognitive association of present moment subjective experience (e.g., sensations, emotions, thoughts) with the self-underlies various forms of maladaptation. We theorize that mindfulness contributes to mental health by engendering Experiential Selfless Processing (ESLP)-processing present moment subjective experience without self-referentiality. To help advance understanding of these processes we aimed to develop an implicit, behavioral measure of ESRP and ESLP of fear, to experimentally validate this measure, and to test the relations between ESRP and ESLP of fear, mindfulness, and key psychobehavioral processes underlying (mal)adaptation. One hundred 38 adults were randomized to 1 of 3 conditions: control, meta-awareness with identification, or meta-awareness with disidentification. We then measured ESRP and ESLP of fear by experimentally eliciting a subjective experience of fear, while concurrently measuring participants' cognitive association between her/himself and fear by means of a Single Category Implicit Association Test; we refer to this measurement as the Single Experience & Self Implicit Association Test (SES-IAT). We found preliminary experimental and correlational evidence suggesting the fear SES-IAT measures ESLP of fear and 2 forms of ESRP-identification with fear and negative self-referential evaluation of fear. Furthermore, we found evidence that

							ESRP and ESLP are associated with meta-awareness (a core process of mindfulness), as well as key psychobehavioral processes underlying (mal)adaptation. These findings indicate that the cognitive association of self with experience (i.e., ESRP) may be an important substrate of the sense of self, and an important determinant of mental health. Haelberg-Weyandt, Wilfried	2022	Die Diagnose - Ntzlich und problemtrchtig	Gesprchspsych ootherapie und Personzentrierte Beratung	53	4	11-13	In dem Artikel werden Vorteile und der Nutzen sowie mgliche Nachteile im Zusammenhang mit der Vergabe von Diagnosen psychischer Strungen diskutiert.
Hagehlsmann, Heinrich; Hagehlsmann, Ute	2017	Populismus - vorlufige Gedanken zu einem regressiven Phnomen	Zeitschrift fr Transaktionsana lyse	34	2	103-121	Das Phnomen des Populismus wird thematisiert und es werden transaktionsanalytischen Konzepte als geeignete Gegenmanahmen prsentiert, um dieser Entwicklung Einhalt gebieten zu knnen. In Zeiten des Umbruchs empfinden viele Menschen Angst. Sie fhlen sich ohnmchtig, misstrauen denjenigen, die das Sagen haben, und frchten, von ihnen bevorteilt zu werden. Zur Kompensation flchten sie sich in regressive Bewltigungsstrategien. Damit einher geht der Wunsch nach einem "charismatischen" Fhrer. Folgende Thesen werden diskutiert: (1) Angst und Stress befrdern Regression, (2) Regression verhindert Autonomie und (3) Regression bedarf der Behandlung, nicht der Verurteilung.
Hahn, Alexis; Paquin, Jill D.; Glean, Ercilla; McQuillan, Kathleen; Hamilton, Deanna	2022	Developing into a group therapist: An empirical investigation of expert group therapists'	American Psychologist	77	5		Group therapy is a ubiquitous treatment modality. And its recent recognition as an APA specialty reflects both its empirical bases of support as a clinical intervention, as well as the decades of work that have gone into establishing competency standards for its practice. The present study seeks to add to this literature by examining how one develops into a group therapist, and how to best

		training experiences					train group therapists to meet competencies. Specifically, for those who have achieved “expertness” in the practice of group work, this grounded theory (GT) study explores both how have they done so and how such practitioners, in turn, train and evaluate effectiveness in their group therapy trainees. Through analysis of in-depth interviews with nine peer-nominated expert group therapists, essential components of their development included an emphasis on experiential training, personal therapy, didactic coursework, participating in professional conferences, and simply enjoying group work. The study also identifies common competencies that these experts look for to determine effectiveness among their trainees, as well as how these experts determine their own level of effectiveness (and how these processes differ). Finally, the study proposes an emergent theoretical model as to how one develops a professional identity as a group therapist. Study limitations and implications for practice, training, advocacy, and research are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Hall, Jennifer D.; Danna, Maria N.; Hoefft, Theresa J.; Solberg, Leif I.; Takamine, Linda H.; Fortney, John C.; Nolan, John Paul; Cohen, Deborah J.	2022	Patient and Clinician Perspectives on Two Telemedicine Approaches for Treating Patients with Mental Health Disorders in Underserved Areas	Journal of the American Board of Family Medicine : JABFM	35	3	465–474	BACKGROUND: Primary care practices in underserved and/or rural areas have limited access to mental health specialty resources for their patients. Telemedicine can help address this issue, but little is known about how patients and clinicians experience telemental health care. METHODS: This pragmatic randomized effectiveness trial compared telepsychiatry collaborative care, where telepsychiatrists provided consultation to primary care teams, to a referral approach, where telepsychiatrists and telepsychologists assumed responsibility for treatment. Twelve Federally Qualified Health Centers in rural and/or underserved areas in 3 states participated. RESULTS: Patients and clinicians

						<p>reported that both interventions alleviated barriers to accessing mental health care, provided quality treatment, and offered improvements over usual care. Telepsychiatry collaborative care was identified as better for patients with difficulty developing trust with new providers. This approach also required more primary care involvement than referral care, creating more opportunities for clinician learning related to mental health diagnosis and treatment. The referral approach was identified as better suited for patients with higher complexity or desiring specific psychotherapies. CONCLUSIONS: Both approaches addressed patient needs and provided access to specialty mental health care. Each approach better aligned with different patients' needs, suggesting that having both approaches available to practices is optimal for supporting patient-centered care.</p>
<p>Hallam, Craig; Simmonds-Buckley, Melanie; Kellett, Stephen; Greenhill, Beth; Jones, Andrew</p>	<p>2021</p>	<p>The acceptability, effectiveness, and durability of cognitive analytic therapy: Systematic review and meta-analysis</p>	<p>Psychology and psychotherapy</p>	<p>94 Suppl 1</p>	<p>8–35</p>	<p>OBJECTIVES This paper sought to conduct a meta-analysis of the effectiveness and durability of cognitive analytic therapy (CAT) and assess the acceptability of CAT in terms of dropout rates. DESIGN Systematic review and meta-analysis. METHODS PROSPERO registration: CRD42018086009. Searches identified CAT treatment outcome studies eligible to be narratively synthesized. Pre-post/post-follow-up effect sizes (ESs) were extracted and synthesized in a random-effects meta-analysis. Variations in effect sizes were explored using moderator analyses. Dropout rates were extracted. Secondary analyses synthesized between-group ES from trials of CAT. RESULTS</p>

							<p>Twenty-five studies providing pre-post CAT treatment outcomes were aggregated across three outcome comparisons of functioning, depression, and interpersonal problems. CAT produced large pre-post improvements in global functioning (ES = 0.86; 95% CI 0.71-1.01, N = 628), moderate-to-large improvements in interpersonal problems (ES = 0.74, 95% CI 0.51-0.97, N = 460), and large reductions in depression symptoms (ES = 1.05, 95% CI 0.80-1.29, N = 586). All these effects were maintained or improved upon at follow-up. Limited moderators of CAT treatment effect were identified. CAT demonstrated small-moderate, significant post-treatment benefits compared to comparators in nine clinical trials (ES = 0.36-0.53; N = 352). The average dropout rate for CAT was 16% (range 0-33%).</p> <p>CONCLUSIONS</p> <p>Patients with a range of presenting problems appear to experience durable improvements in their difficulties after undergoing CAT. Recommendations are provided to guide the further progression of the CAT outcome evidence base.</p> <p>PRACTITIONER POINTS</p> <p>Large pre-post reductions in global functioning and depression outcomes and moderate-large reductions in interpersonal problems are evident after CAT. The effects of CAT appear durable, and interpersonal functioning significantly improves over follow-up time. CAT produces small-moderate benefits compared to trial comparators. CAT appears to be an engaging psychotherapy that maintains patients in treatment.</p>
Hallgren, Kevin A.; Holzhauer, Cathryn G.;	2021	Optimizing the length and reliability of	Journal of consulting and	89	4	277–287	<p>Objective: Clients who receive alcohol use disorder (AUD) treatment experience variable outcomes. Measuring clinical progress during treatment using standardized</p>

<p>Epstein, Elizabeth E.; McCrady, Barbara S.; Cook, Sharon</p>		<p>measures of mechanisms of change to support measurement-based care in alcohol use disorder treatment</p>	<p>clinical psychology</p>			<p>measures (i.e., measurement-based care) can help indicate whether clinical improvements are occurring. Measures of mechanisms of behavioral change (MOBCs) may be particularly well-suited for measurement-based care; however, measuring MOBCs would be more feasible and informative if measures were briefer and if their ability to detect reliable change with individual clients was better articulated. Method: Three abbreviated measures of hypothesized MOBCs (abstinence self-efficacy, coping strategies, anxiety) and a fourth full-length measure (depression) were administered weekly during a 12-week randomized trial of cognitive-behavioral therapy (CBT) for women with AUD. Psychometric analyses estimated how reliably each measure distinguished within-person change from between-person differences and measurement error. Reliability coefficients were estimated for simulated briefer versions of each instrument (i.e., instruments with fewer items than the already-abbreviated instruments) and rates of reliable improvement and reliable worsening were estimated for each measure. Results: All four measures had good reliability (.86–.90) for detecting within-person change. Many participants (41.4%–62.5%) reliably improved on MOBCs from first to last treatment session. Reliable improvement on MOBCs was associated with reductions in percentage of drinking days (PDD) at 3, 9, and 15-month follow-ups. Simulated briefer versions of each instrument retained good reliability for detecting change with only 3 (self-efficacy), 11 (coping strategies), 5 (anxiety), or 10 items (depression). Conclusions: Brief MOBC measures can detect reliable change for individuals in AUD treatment. Routinely measuring MOBCs may help with monitoring clinical progress.</p>

Hammen, Jessica L.; Norman, Sonya B.; Sonis, Jeffrey H.; Phelps, Andrea J.; Bisson, Jonathan I.; Nunes, Vanessa D.; Megnin-Viggars, Odette; Forbes, David; Riggs, David S.; Schnurr, Paula P.	2019	A guide to guidelines for the treatment of posttraumatic stress disorder in adults: An update	Psychotherapy	56	3	359–373	Clinical practice guidelines (CPGs) are used to support clinicians and patients in diagnostic and treatment decision-making. Along with patients' preferences and values, and clinicians' experience and judgment, practice guidelines are a critical component to ensure patients are getting the best care based on the most updated research findings. Most CPGs are based on systematic reviews of the treatment literature. Although most reviews are now restricted to randomized controlled trials, others may consider nonrandomized effectiveness trials. Despite a reliance on similar procedures and data, methodological decisions and the interpretation of the evidence by the guideline development panel can result in different recommendations. In this article, we will describe key methodological points for 5 recently released CPGs on the treatment of posttraumatic stress disorder in adults and highlight some of the differences in both the process and the subsequent recommendations. Hameed, M.; O'Doherty, L.; Gilchrist, G.; Tirado-Muñoz, J.; Taft, A.; Chondros, P.; Feder, G.; Tan, M.; Hegarty, K.	2020	Psychological therapies for women who experience intimate partner violence	Cochrane Database of Systematic Reviews	CD013017. doi:10.1002/14651858.CD013017.pub2	7		Abstract - Background Intimate partner violence (IPV) against women is prevalent and strongly associated with mental health problems. Women experiencing IPV attend health services frequently for mental health problems. The World Health Organization recommends that women who have experienced IPV and have a mental health diagnosis should receive evidence-based mental health treatments. However, it is not known if psychological therapies work for women in the context of IPV and whether they cause harm. Objectives To assess the effectiveness of psychological therapies for women who experience IPV on the primary outcomes of depression,

							<p>self-efficacy and an indicator of harm (dropouts) at six- to 12-months' follow-up, and on secondary outcomes of other mental health symptoms, anxiety, quality of life, re-exposure to IPV, safety planning and behaviours, use of healthcare and IPV services, and social support. Search methods We searched the Cochrane Common Mental Disorders Controlled Trials Register (CCMDCTR), CENTRAL, MEDLINE, Embase, CINAHL, PsycINFO, and three other databases, to the end of October 2019. We also searched international trials registries to identify unpublished or ongoing trials and handsearched selected journals, reference lists of included trials and grey literature. Selection criteria We included randomised controlled trials (RCTs), quasi-RCTs, cluster-RCTs and cross-over trials of psychological therapies with women aged 16 years and older who self-reported recent or lifetime experience of IPV. We included trials if women also experienced co-existing mental health diagnoses or substance abuse issues, or both. Psychological therapies included a wide range of interventions that targeted cognition, motivation and behaviour compared with usual care, no treatment, delayed or minimal interventions. We classified psychological therapies according to Cochrane Common Mental Disorders's psychological therapies list. Data collection and analysis Two review authors extracted data and undertook 'Risk of Bias' assessment. Treatment effects were compared between experimental and comparator interventions at short-term (up to six months post-baseline), medium-term (six to under 12 months, primary outcome time point), and long-term follow-up (12 months and above). We used standardised mean difference (SMD) for continuous and odds ratio (OR) for dichotomous outcomes, and used random-</p>
--	--	--	--	--	--	--	---

						<p>effects meta-analysis, due to high heterogeneity across trials. Main results We included 33 psychological trials involving 5517 women randomly assigned to experimental (2798 women, 51%) and comparator interventions (2719 women, 49%). Psychological therapies included 11 integrative therapies, nine humanistic therapies, six cognitive behavioural therapy, four third-wave cognitive behavioural therapies and three other psychologically-orientated interventions. There were no trials classified as psychodynamic therapies. Most trials were from high-income countries (19 in USA, three in Iran, two each in Australia and Greece, and one trial each in China, India, Kenya, Nigeria, Pakistan, Spain and UK), among women recruited from healthcare, community, shelter or refuge settings, or a combination of any or all of these. Psychological therapies were mostly delivered face-to-face (28 trials), but varied by length of treatment (two to 50 sessions) and staff delivering therapies (social workers, nurses, psychologists, community health workers, family doctors, researchers). The average sample size was 82 women (14 to 479), aged 37 years on average, and 66% were unemployed. Half of the women were married or living with a partner and just over half of the participants had experienced IPV in the last 12 months (17 trials), 6% in the past two years (two trials) and 42% during their lifetime (14 trials). Whilst 20 trials (61%) described reliable low-risk random-sampling strategies, only 12 trials (36%) described reliable procedures to conceal the allocation of participant status. While 19 trials measured women's depression, only four trials measured depression as a continuous outcome at medium-term follow-up. These showed a probable beneficial effect of psychological therapies in</p>
--	--	--	--	--	--	---

						<p>reducing depression (SMD -0.24, 95% CI -0.47 to -0.01; four trials, 600 women; moderate-certainty evidence). However, for self-efficacy, there may be no evidence of a difference between groups (SMD -0.12, 95% CI -0.33 to 0.09; one trial with medium-term follow-up data, 346 women; low-certainty evidence). Further, there may be no difference between the number of women who dropped out from the experimental or comparator intervention groups, an indicator of no harm (OR 1.04, 95% CI 0.75 to 1.44; five trials with medium-term follow-up data, 840 women; low-certainty evidence). Although no trials reported adverse events from psychological therapies or participation in the trial, only one trial measured harm outcomes using a validated scale. For secondary outcomes, trials measured anxiety only at short-term follow-up, showing that psychological therapies may reduce anxiety symptoms (SMD -0.96, 95% CI -1.29 to -0.63; four trials, 158 women; low-certainty evidence). However, within medium-term follow-up, low-certainty evidence revealed that there may be no evidence between groups for the outcomes safety planning (SMD 0.04, 95% CI -0.18 to 0.25; one trial, 337 women), post-traumatic stress disorder (SMD -0.24, 95% CI -0.54 to 0.06; four trials, 484 women) or re-exposure to any form of IPV (SMD 0.03, 95% CI -0.14 to 0.2; two trials, 547 women). Authors' conclusions There is evidence that for women who experience IPV, psychological therapies probably reduce depression and may reduce anxiety. However, we are uncertain whether psychological therapies improve other outcomes (self-efficacy, post-traumatic stress disorder, re-exposure to IPV, safety planning) and there are limited data on harm. Thus, while psychological therapies probably improve emotional</p>
--	--	--	--	--	--	---

						<p>health, it is unclear if women's ongoing needs for safety, support and holistic healing from complex trauma are addressed by this approach. There is a need for more interventions focused on trauma approaches and more rigorous trials (with consistent outcomes at similar follow-up time points), as we were unable to synthesise much of the research. Plain language summary Psychological therapies for women who experience intimate partner violence The review question Domestic violence (physical, emotional, sexual abuse and controlling behaviour by a partner or ex-partner) is common worldwide and causes long-lasting emotional and physical health problems. Psychological therapies (counselling by trained people) may improve women's mental health and enable them to focus on making safety plans, accessing resources for themselves and their children, and ultimately to escape the domestic violence. We searched scientific literature worldwide up to the end of October 2019 for trials comparing a group of female domestic violence survivors who received psychological therapy with those who did not, to understand whether such therapies are safe and effective. Trial characteristics Women had been randomly placed in one group (the intervention) or the other (comparison). We found 33 trials involving 5517 women, with an average age of 37 years, and two-thirds of them were unemployed. Half of them were married or living with a partner, and for half of them the domestic violence was in the last 12 months. Psychological therapies were mostly delivered face-to-face but varied by the length of treatment (2 to 50 sessions) and the staff who delivered the therapies (social workers, nurses, psychologists, community health workers, family doctors, researchers). Women were</p>
--	--	--	--	--	--	---

						invited from healthcare settings, community centres and domestic violence refuges and shelters. Nineteen trials measured women's depression, two assessed self-efficacy (if women believed they were capable of making changes in their lives) and all measured dropout from the groups. We used the number of dropouts to measure harmful effects. Most trials followed up on the women within six months of starting the trial. Key results We found evidence that psychological therapies probably reduce depression and may reduce anxiety symptoms for women who have experienced domestic violence (six to 12 months after the therapy). Psychological therapies do not appear to cause any harm. However, we are uncertain whether psychological therapies improve self-efficacy, mental health, quality of life, social support, uptake of healthcare and domestic violence services, safety planning or reduce post-traumatic stress disorder and re-exposure to any form of domestic violence. Overall, there is a need for more trials with consistent outcomes at similar follow-up time points as we were unable to combine much of the research to give an overall picture. Thus, while women experiencing domestic violence may be helped by psychological therapies to improve their emotional health, which may in turn help their ongoing needs of safety, support and holistic healing from complex trauma, we are uncertain whether psychological therapies improve these aspects of their lives.
Hamlett, Nakia M.; Carr, Erika R.; Hillbrand, Marc	2016	Positive behavioral support planning in the inpatient treatment of	Psychological Services	13	2	Positive behavior support (PBS) plans are increasingly used on inpatient units to assess and treat serious and dangerous behaviors displayed by patients with serious psychiatric impairment. A contemporary extension of traditional applied behavior analytic procedures, PBS plans integrate theories from several domains with

		severe disruptive behaviors: A description of service features				<p>perspectives on community psychology, positive psychology, and recovery-oriented care. Because there is little evidence to suggest that more invasive, punitive disciplinary strategies lead to long-term positive behavioral change (Parkes, 1996), PBS plans have emerged as an alternative to the use of seclusion and restraint or other forms of restrictive measures typically used on inpatient psychiatric units (Hammer et al., 2011). Moreover, PBS plans are a preferred method of intervention because more invasive interventions often cause more harm than good to all involved (Elliott et al., 2005). This article seeks to provide an integrated framework for the development of positive behavior support plans in inpatient psychiatric settings. In addition to explicating the philosophy and core elements of PBS plans, this work includes discussion of the didactic and pragmatic aspects of training clinical staff in inpatient mental health settings. A case vignette is included for illustration and to highlight the use of PBS plans as a mechanism for helping patients transition to less restrictive settings. This work will add to the scant literature examining the use of positive behavioral support plans in inpatient psychiatric settings. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Hammer, Andrea; Hofer-Freundorfer, Sabine; Croy, Antonia; Ettl, Christa; Kienzl, Simone; Prohaska, Martina	2018	"Brcken bauen" - In Kontakt-Kommen mit Menschen am Rand des psychotherapeutischen Interesses				<p>Die unterschiedlichen Anwendungsbereiche der Pr-Therapie werden thematisiert. Aufgezeigt wird die Wirksamkeit vor allem in der Arbeit mit Kindern und Jugendlichen mit geistiger Behinderung, im schulischen Bereich mit Jugendlichen mit Affektdurchbrchen und in der Betreuung von Menschen mit schweren Demenzerkrankungen. All diesen Beispielen ist gemeinsam, dass es durch die Anwendung der Kontaktreflexionen gelungen ist, in Ausnahmesituationen,</p>

							in denen die Kinder und Jugendlichen keinen Kontakt zu ihrer Umgebung aufnehmen konnten, diesen Kontakt herzustellen und damit eine Grundlage für einen Beziehungsaufbau zum Therapeuten zu schaffen. Um als Therapeut hilfreich sein zu können ist es unumgänglich, nicht gemeinsam mit dem Klienten in seiner Welt zu versinken, sondern "am Boden zu bleiben". Dafür ist erforderlich, dass ein Kontakt auf unterschiedlichen Ebenen wiederhergestellt wird - sowohl affektiv als auch zur Realität. Wenn das gelungen ist, ist auch eine Kommunikation zwischen Therapeut und Klient möglich.
Han, Jeehee; Park, Sangwoo; Kim, Sung Hae	2022	Supporting decision-making regarding fertility preservation in patients with cancer: An integrative review	European journal of cancer care	31	6	e13748	INTRODUCTION: Recent reproductive technology for cancer patients has provided multiple options to preserve their fertility. Preserving fertility can increase quality of life of cancer patients. However, medical service providers and patients face difficulties in the decision-making process for the fertility preserving treatment because studies focusing on the concept of decision-making and various intervention materials are lack. This review aims to identify the attributes of interventions of studies on decision-making support interventions in cancer patients considering fertility preservation and provide best evidence for health professionals. METHODS: PubMed, CINAHL, Embase, Cochrane CENTRAL and DBpia databases were searched. An integrated review of the literature was conducted using Whittemore and Knaf's methodology. RESULTS: The search identified 1008 articles, of which 11 studies met eligible criteria. The attributes of the interventions were (1) provision of detailed and practical information of fertility preservation, (2) nondirective approaches to help patients to value their judgements, (3) emphasis on interactions through individualised consultations, (4) establishing connections

							with available resources and (5) reinforcement of decision-making support resources. CONCLUSION: Health professionals must acquire current knowledge and ethical and legal standards of fertility preservation and pass this information on to patients before the formation of fertility preservation decision-making support networks within the hospital and health systems.
Hankir, Ahmed; Kirkcaldy, Bruce; Carrick, Frederick R.; Sadiq, Asad; Zaman, Rashid	2017	The performing arts and psychological well-being	Psychiatria Danubina	29	Suppl 3	196–202	Although psychotropic drugs have been hailed as, 'One of the success stories of modern psychiatry' the prescribing of these medicines has not been without commotion, concern and controversy. Moreover, the President of the World Psychiatry Association Professor Dinesh Bhugra and colleagues, after conducting a recent large-scale study (n=25,522) on psychiatric morbidity in the UK, collectively issued the clarion call that, 'The mental health of the nation was unlikely to be improved by treatment with psychotropic medication alone'. The provision of mental healthcare services may likely benefit from a holistic approach that includes a variety of treatment options that prioritizes patient safety and preference. The performing arts is gaining popularity among service users as an adjunctive form of treatment for mental illness. There is a growing body of evidence that provisionally supports the claim that art therapy, 'Possesses the power to heal psychological wounds'. The North American Drama Therapy Association defines drama therapy as, 'The intentional use of drama and/or theatre processes to achieve therapeutic goals' and that it is 'active and experiential'. This review article discusses and describes the merits of dramatherapy and how this treatment modality can contribute to a patient's recovery from psychological distress.

Hannaford, Sophie; Shaw, Rhonda; Walker, Renee	2019	Older Adults' Perceptions of Psychotherapy: What Is It and Who Is Responsible?	Australian Psychologist	54	1	37-45	
Hannse, Christin; Drckler, Annika; Krger, Christoph	2023	Einsatz von Demonstrationsvideos zur Psychotherapie im Psychologiestudium. Eine randomisiert-kontrollierte Studie zur Vermittlung praxisbezogener und verfahrensspezifischer Inhalte	Zeitschrift fr Klinische Psychologie und Psychotherapie			1-10	Theoretischer Hintergrund: Demonstrationsvideos (DVs) mit Simulationspatientinnen und -patienten sind eine innovative Lehrmethode. Fragestellung: Eignen sich DVs fr die Lehre verschiedener Psychotherapieverfahren im Bachelorstudium Psychologie und als Klausurvorbereitung? Methode: In einer Pilotstudie wurde Studierenden je ein DV zur tiefenpsychologischen, gesprchspsychotherapeutischen, verhaltenstherapeutischen und systemischen Therapie nach der dazugehrgen Vorlesung gezeigt. Das Abschneiden der Studierenden in verfahrensspezifischen Klausurfragen wurde mit den Ergebnissen aus dem Vorjahr verglichen. In einer zweiten, randomisiert-kontrollierten Studie (RCT) wurden dieselben DVs im Vergleich zu Lehrbuchtexten nach der Vorlesung eingesetzt. Anschließend beantworteten die Studierenden Fragen zu verfahrensspezifischem Wissen und bewerteten verfahrensspezifische Merkmale. Ergebnisse: In der Pilotstudie schnitt die Studiengruppe mit DVs (n = 59) in Klausurfragen besser ab als die Gruppe aus dem Vorjahr ohne DVs (n = 65). In der RCT (n = 43 - 53) konnte die Videogruppe die Wissensabfrage zur Tiefenpsychologie und Verhaltenstherapie besser beantworten. Verfahrensspezifische Merkmale wurden teilweise erkannt. Schlussfolgerungen: DVs sind eine vielversprechende Lehrmethode, jedoch Lehrbuchtexten nicht immer berlegen.

Hansch, Dietmar	2021	Verfahrensintegrierende Verhaltenstherapie bei Angsterkrankungen - Lernen und Verlernen von pathologischer Angst als ganzheitlicher Prozess	Gestalt Theory	43	2	215–230	Nicht zu Unrecht gilt die Behandlung von Angsterkrankungen als die Paradedisziplin der Verhaltenstherapie (VT). Hier wie auch generell zeigt sich die VT dabei aber als zersplittert in eine Vielzahl von Einzelmethoden: Verschiedene Lernformen - Einsichtslernen, Konditionierungslernen und Habituationlernen - werden in ihrem Beitrag zu Angsterkrankungen isoliert voneinander konzipiert. Entsprechend stehen auch auf diesen Lernformen basierende Therapiemethoden für sich. Dadurch werden wichtige Synergiepotenziale verschenkt. Menschliches Lernen, auch und gerade das Lernen und Verlernen von pathologischer Angst, ist aber immer ein ganzheitlicher Prozess. Der Artikel skizziert eine ganzheitliche Psychologie der Eskalation und Chronifizierung pathologischer Angst unter integrierendem Einbezug der o.g. Lernformen. Hieraus leitet sich eine verfahrensintegrierende VT ab, die die etablierten Behandlungsmethoden so kombiniert, dass Synergiegewinne entstehen, was an einem Fallbeispiel verdeutlicht wird. Den theoretischen Hintergrund bildet die Theorie der Selbstorganisation komplexer Systeme, insbesondere die Synergetik - ein Feld, in dem wichtige Aspekte der Gestalttheorie aufgehoben sind.
Hansen, Anette; Hauge, Solveig; Bergland, Ådel	2017	Meeting psychosocial needs for persons with dementia in home care services - a qualitative study of different	BMC geriatrics	17	1	211	BACKGROUND: The majority of persons with dementia are home-dwelling. To enable these persons to stay in their own homes as long as possible, a holistic, individual and flexible care is recommended. Despite a requirement for meeting psychological, social and physical needs, home care services seem to focus on patients' physical needs. Accordingly, the aim of this study was to explore how the psychosocial needs of home-dwelling, older persons with dementia were perceived, emphasized and

		perceptions and practices among health care providers					met by home care services. METHODS: A descriptive, qualitative approach was used. Data were collected through semi-structured focus group interviews with 24 health care providers in home care services from four municipalities. Data were analysed using systematic text condensation. RESULTS: This study showed major differences in how health care providers perceived the psychosocial needs of older home-dwelling persons with dementia and how they perceived their responsibilities for meeting those psychosocial needs. The differences in the health care providers' perceptions seemed to significantly influence the provided care. Three co-existing logics of care were identified: the physical need-oriented logic, the renouncement logic and the integrated logic. CONCLUSIONS: The differences in how health care providers perceived the psychosocial needs of persons with dementia and their responsibilities for meeting those needs, influenced how the psychosocial needs were met. These differences indicates a need for a clarification of how psychosocial needs should be conceptualized and who should be responsible for meeting these needs. Further, increased competence and increased consciousness of psychosocial needs and how those needs can be met, are essential for delivering high-quality holistic care that enables persons with dementia to live in their own home for as long as possible.
Hanswille, Reinert; Wienand-Kranz, Dorothee; Eckert, Jochen; Brito Santos-Dodt, Mareke	2016	"Wenn sich die geplante Psychotherapie weiterbildung nicht zu einem 'closed shop' entwickeln soll,	Psychotherapeutenjournal	15	2	142-150	Das Psychotherapeutenjournal seine Reihe mit Interviews zur Reform der Ausbildung fort. Gesprächspsychotherapie (GPT) und Systemische Therapie (ST) sind die beiden Psychotherapieverfahren, denen nach Einfhrgung des Psychotherapeutengesetzes die wissenschaftliche Anerkennung durch den Wissenschaftlichen Beirat Psychotherapie (WBP) erteilt wurde, sodass eine zur

de; Thielen, Manfred		bentigen wir kreative Lösungen"				<p>Approbation fhrende Ausbildung mit diesen Schwerpunkten mglich wurde. Beiden Verfahren fehlt jedoch die sozialrechtliche Anerkennung durch den Gemeinsamen Bundesausschuss (G-BA). Im Unterschied zu den Ausbildungsinstituten der Richtlinienverfahren knnen hier also die in der Ausbildung zu erbringenden Psychotherapien nicht ber die gesetzlichen Krankenkassen abgerechnet werden. Fr 600 Stunden Psychotherapie mssen Selbstzahler gefunden werden und die Absolventinnen und Absolventen dieser Ausbildung bleiben auf Verdienstmglichkeiten auerhalb der gesetzlichen Krankenkassen angewiesen. So ist zu fragen, welche Konsequenzen sich daraus fr die jetzige Ausbildung mit dem Schwerpunkt GPT bzw. ST ergeben und welche Hoffnungen mit der Reform verknpt sind. Wir haben mit Dr. Dorothee Wienand-Kranz, Ausbildungsleiterin im Schwerpunkt GPT am Institut fr Psychotherapie der Universitt Hamburg (IfP) und Professor Dr. Jochen Eckert, stellv. geschftsfhrender Direktor am IfP, sowie mit Reinert Hanswille, Leiter am Institut fr Systemische Familientherapie, Supervision und Organisationsentwicklung (ifs) in Essen gesprochen. Steht die GPT vor dem Aus? Bleibt die Systemische Therapie weiterhin stark nachgefragt? Wird in dem geplanten Direktstudium eine Chance fr die Lehre in den vier Grundorientierungen - Verhaltenstherapie, Psychodynamische Psychotherapie, Systemische Therapie und Humanistische Psychotherapie - gesehen? Wird sich die Verfahrensvielfalt auch in der Weiterbildung nicht durchsetzen knnen? Die Vertreter der beiden Institute nehmen dazu Stellung, formulieren Erwartungen und Wnsche, aber auch Bedenken und Skepsis.</p>

Hara, Kimberley M.; Westra, Henny A.; Coyne, Alice E.; Di Bartolomeo, Alyssa A.; Constantino, Michael J.; Antony, Martin M.	2022	Therapist affiliation and hostility in cognitive-behavioral therapy with and without motivational interviewing for severe generalized anxiety disorder	Psychotherapy research : journal of the Society for Psychotherapy Research	32	5	598–610	<p>OBJECTIVE: Although therapist supportive, rather than directive, strategies have been particularly indicated during client resistance, little systematic research has examined how therapists responsively navigate resistance in different therapy approaches and how this responsiveness is related to outcome. METHOD: In the context of disagreement episodes in cognitive-behavioral therapy (CBT) for generalized anxiety disorder (GAD; Westra, H. A., Constantino, M. J., & Antony, M. M. Integrating motivational interviewing with cognitive-behavioral therapy for severe generalized anxiety disorder: An allegiance-controlled randomized clinical trial. <i>Journal of Consulting and Clinical Psychology</i>, 84(9), 768-782. https://doi.org/10.1037/ccp0000098, 2016), the present study examined (1) the degree to which therapist management of resistance differed between therapists trained in CBT integrated with motivational interviewing (MI-CBT; i.e., training centered on the responsive management of resistance) and therapists trained in CBT-alone, and (2) the impact of specific therapist behaviors during disagreement on client worry outcomes immediately posttreatment and 1-year posttreatment. Episodes of disagreement were rated used the Structural Analysis of Social Behavior (Benjamin, L. S. Structural analysis of social behavior. <i>Psychological Review</i>, 81(5), 392-425. https://doi.org/10.1037/h0037024, 1974).</p> <p>RESULTS: Therapists trained in MI-CBT were found to exhibit significantly more affiliative and fewer hostile behaviors during disagreement compared to those trained in CBT-alone; both of these, in turn, were found to mediate client 1-year posttreatment outcomes, such that increased affiliation during disagreement was associated with improved outcomes. CONCLUSION: This study</p>
---	------	--	--	----	---	---------	--

							highlights the value of training therapists in the responsive detection and management of resistance, as well as the systematic integration of MI into CBT.
Hardin, Kaitlin M.; Contreras, Isaias M.; Kosiak, Klaudia; Novaco, Raymond W.	2022	Anger rumination and imagined violence as related to violent behavior before and after psychiatric hospitalization	Journal of clinical psychology	78	9	1878–1895	<p>OBJECTIVE Anger rumination and imagined violence, in the context of anger/aggression proclivity, are examined for their direct and conjoint associations with violent behavior by psychiatric patients.</p> <p>METHOD A secondary analysis of data from the MacArthur Violence Risk Study was conducted with 1136 acute civil commitment patients, assessed during hospitalization and after hospital discharge. Anger/aggression proclivity was assessed with the Brief Psychiatric Rating Scale hostility subscale, anger rumination was indexed using items from the Novaco Anger Scale, and imagined violence was measured with Grisso's Schedule of Imagined Violence. Violence, prehospitalization and posthospitalization, was indexed by the MacArthur project measure.</p> <p>RESULTS Correlational analyses, mediation analyses, and moderated mediation analyses were conducted. Anger rumination significantly predicted pre- and posthospitalization violence, when controlling for age, sex, race, childhood physical abuse, and anger/aggression proclivity; and it partially mediated the relation between anger/aggression proclivity and violence. Imagined violence and anger rumination were highly inter-related. When imagined violence was added to the regression model, it was a significant predictor of prehospitalization violence; however, it did not moderate the association of anger rumination with pre- or</p>

							<p>posthospitalization violence.</p> <p>CONCLUSION</p> <p>Anger rumination may be a mechanism through which anger activates violent behavior, which has important implications for psychotherapeutic intervention targeting. Future research should investigate the association between anger rumination and imagined violence, with attention given to revenge planning as a link.</p>
Hardy, Nathan R.; Fisher, Adam R.	2018	Attachment Versus Differentiation: The Contemporary Couple Therapy Debate	Family process	57	2	557-571	<p>This paper reviews the current debate between differentiation and attachment in treating couples through exploring the tenets of crucible therapy (Schnarch, 1991) and emotionally focused couple therapy (Johnson, 2004). We provide a review of the two theories-as well as the two "pure form" example models- and explore the debate in light of the integrative movement in couple and family therapy (Lebow, 2014). We also examine points of convergence of the two theories and models, and provide clinicians and researchers with an enhanced understanding of their divergent positions. Both differentiation and attachment are developmental theories that highlight the human experience of balancing individuality and connection in adulthood. The two models converge in terms of metaconcepts that pervade their respective theories and approach. Both models capitalize on the depth and importance of the therapeutic relationship, and provide rich case conceptualization and processes of therapy. However, they substantially differ in terms of how they view the fundamental aspects of adult development, have vastly divergent approaches to how a therapist intervenes in the room, and different ideas of how a healthy couple should function. In light of the deep polarization of the two models, points of integration-</p>

							particularly between the broader theories of attachment and differentiation-are offered for therapists to consider. 2018 Family Process Institute.
Harms, Louise	2017	Trauma und Resilienz. Symptome verstehen, Heilung fördern					<p>Im Kontext des Themas "Trauma und Resilienz" werden bedeutsame Ansätze zur Frage vorgestellt, wie Menschen traumatische Lebenserfahrungen bewältigen. In der Praxis stehen medikalisierte und psychiatrische Theorien und Behandlungsmethoden Seite an Seite mit soziologischen und anthropologischen Ansätzen. Für manche Verfahren wie die kognitive Verhaltenstherapie ist eine rasche Effizienz nachgewiesen. Andere Verfahren, etwa die psychodynamischen und narrativen Methoden, können zwar keine damit vergleichbare empirische Evidenzgrundlage vorweisen, finden aber gleichermaßen Anklang bei Berlebenden, Klinikern und Wissenschaftlern. Ziel dieses Buches ist es, Fachleuten eine Ressource an die Hand zu geben, die all diese verschiedenen Sichtweisen des Traumas, der Resilienz und der Genesung zusammenführt - zur Unterstützung der Betroffenen. Zur Illustration der Herangehensweisen und Unterstützung des Transfers in den eigenen Praxisalltag werden Fallbeispiele angeführt. - Inhalt: (1) Trauma- und Resilienztheorien. (2) Psychodynamische Theorien: die Reintegration des Selbst. (3) Bindungstheorien und -therapien: die Regulation des Selbst und der Beziehungen. (4) Symptombasierte Ansätze. Reduzierung der PTBS-Symptomatik. (5) Personenzentrierte Verfahren: die Wiederherstellung der Kongruenz. (6) Narrative Ansätze: Wiederaneignung von Bedeutung und Kohärenz. (7) Soziokologische Ansätze: Systeme wiederaufbauen und erhalten. (8) Antirepressive Ansätze: Rechte anerkennen und Unterdrückung bekämpfen. (9) Förderung der Resilienz und der Genesung: ein integrativer Ansatz.</p>

Harned, Melanie S.; Fitzpatrick, Skye; Schmidt, Sara C.	2020	Identifying Change Targets for Posttraumatic Stress Disorder Among Suicidal and Self-Injuring Women With Borderline Personality Disorder	J. Traum. Stress (Journal of Traumatic Stress)	33	4	610–616	Research on psychotherapies for posttraumatic stress disorder (PTSD) is increasingly focused on understanding not only which treatments work but why and for whom they work. The present pilot study evaluated the temporal relations between five hypothesized change targets- posttraumatic cognitions, guilt, shame, general emotion dysregulation, and experiential avoidance- and PTSD severity among women with PTSD, borderline personality disorder, and recent suicidal and/or self-injurious behaviors. Participants (N = 26) were randomized to receive 1 year of dialectical behavior therapy (DBT) with or without the DBT prolonged exposure (DBT PE) protocol for PTSD. Potential change targets and PTSD were assessed at 4-month intervals during treatment and at 3-month posttreatment follow-up. Time-lagged mixed-effects models indicated that between-person differences in all change targets except guilt were associated with more severe PTSD, η^2 s = .32-.55, and, except for general emotion dysregulation, slowed the rate of change in PTSD severity over time, η^2 s = .20-.39. In DBT but not in DBT + DBT PE, individuals with higher levels of guilt and experiential avoidance relative to their own average had more severe PTSD at the next assessment point, η^2 s = .12-.25. The associations between the proposed change targets and PTSD severity were not bidirectional, except for general emotion dysregulation, η^2 = .50; and posttraumatic cognitions, η^2 = .06. These preliminary findings suggest that trauma-related cognitions, shame, and guilt, as well as problems regulating them, may be important change targets for improving PTSD in this patient population.
Harrington, Shawn;	2021	Depth of experiencing	Psychology and psychotherapy	94	4	895–914	The purpose of this study was to determine the extent to which therapeutic processes - working alliance and depth

<p>Pascual-Leone, Antonio; Paivio, Sandra; Edmondstone, Christopher; Baher, Tabarak</p>		<p>and therapeutic alliance: What predicts outcome for whom in emotion-focused therapy for trauma?</p>				<p>of experiencing - contributed to outcome. Individual differences in these processes were examined at the early and working phases to determine their impact on symptom reduction. An archival data set of N=42 individuals who underwent emotion-focused therapy for trauma for childhood maltreatment was used to examine the differential quality of client processes throughout treatment. For those who had difficulty forming an alliance early in therapy, alliance scores during the working phase were the best predictor of outcome ($r = -.42$). This was complemented by a process change of improvement in alliance from the early to working phases ($d = 1.0$). In contrast, for those who had difficulty engaging in deepened experiencing early in therapy, depth of experiencing in the working phase was the best predictor of outcome ($r = -.36$). This was complemented by an improvement in depth of experiencing from the early to working phases ($d = .69$). The findings of this study suggest that focusing on the process that clients have trouble with early in therapy contributes to the best treatment outcome. Sometimes early treatment sessions reveal an abundance of one kind of processing but limitations to another, which poses a puzzle for treatment planning. Our findings suggest that within the first four sessions, therapists could develop tailored treatments based on the relative presence or absence of critical therapeutic changes processes. When it becomes evident that therapy is progressing with a weaker alliance between client and therapist, therapists should redouble their efforts in alliance-building. However, when therapy is developing in a fashion that lacks deep emotional experiencing on the part of the client, treatment efforts should aim to facilitate a richer exploration of moment-</p>
---	--	--	--	--	--	---

							by-moment experience. As such, our findings suggest relying on the existing processing strengths within a dyad (e.g., emphasis on an already strong relationships, or augmenting an existing aptitude for deeper experiencing) while shortcomings exist in another kind of process is not optimal responding. Therapists should focus their work on the process that clients have trouble with early in therapy to facilitate the best treatment outcome. 2021 British Psychological Society.
Harris, Jeff E.; Maddoux, John A.; Stretcher, Amanda L.	2016	Testing the impact of Key Strategies Training for Individual Psychotherapy on understanding, confidence, and intention to use skills in practice	Journal of Psychotherapy Integration	26	3	318–325	This study represents a preliminary test of the impact of Key Strategies Training for Individual Psychotherapy (KST-IP), a new method of integrative training for graduate psychology students. Trainees received 8 weeks of training, introducing them to practical skills designed to explore and transform thoughts, feelings, and actions. A total of 24 skills were taught; 4 skills for exploration and 4 skills for transformation for each of 3 theoretical models: cognitive, emotion-focused, and behavioral. After receiving KST-IP, trainees reported increased understanding, confidence, and intention to use skills drawn from all 3 theories. These results provide preliminary support for the feasibility and impact of KST-IP. Future research can be used to overcome limitations associated with the current study. Harrison, Amy; Stavri, Pamela; Tchanturia, Kate	2021	Individual and group format adjunct therapy on social emotional skills for adolescent inpatients with severe and	Neuropsychiatrie : Klinik, Diagnostik, Therapie und Rehabilitation : Organ der Gesellschaft Österreichische	35	4	163–176	BACKGROUND: Relatively little is known about which psychological treatment adjuncts might be helpful for supporting people with the most severe and complex forms of anorexia nervosa (AN) with very low weight and malnutrition requiring inpatient admissions, but targeting key perpetuating factors such as social emotional difficulties may be one way to advance knowledge. This pilot feasibility project reports on the development of an

		complex eating disorders (CREST-A)	r Nervenarzte und Psychiater				adolescent adaptation of Cognitive Remediation and Emotion Skills Training (CREST-A) and explores its acceptability, feasibility and possible benefits. METHODS: An uncontrolled, repeated measures design was employed with data collected at the start and end of treatment. CREST-A was investigated in two formats: a 10-session individual format delivered to a case series of 12 patients and a 5-session group format delivered to 3 groups of 9 patients. RESULTS: Acceptability, measured using a Patient Satisfaction Scale was 7/10 for the individual and 6/10 for the group format. Individual take-up was 100% and group take-up was 34.62%. Drop-out was 8.33% and 29.63% in the individual and group formats respectively. Homework was completed 66.67% and 75% of the time in the individual and group formats respectively. Patients reported medium-sized improvements in components of social emotional functioning measured using the Work and Social Adjustment Scale, the Toronto Alexithymia Scale and the Revised Social Anhedonia Scale in the individual and group formats. CONCLUSION: Future studies employing randomized controlled designs may now be warranted to advance this evidence base of this low intensity treatment adjunct.
Harrison, Phillippa; Hardy, Gillian E.; Barkham, Michael	2019	The relationship between expected engagement and talking therapy outcome	Clinical psychology & psychotherapy	26	4	492-501	The aim of the study was to investigate whether client-reported expected engagement with therapy predicted therapy outcome. It was hypothesized that higher expected engagement with cognitive behavioural therapy (CBT) or person-centred experiential therapy (PCET) would predict more symptomatic improvement following therapy and higher likelihood of therapy completion. The Sheffield Expected Engagement with Therapy Scale was administered to 96 clients at pre-therapy assessment

						with all meeting a diagnosis of moderate or severe depression with 53 receiving CBT and 43 receiving PCET. Higher expected engagement predicted more symptomatic improvement in CBT but not PCET. Expected engagement only predicted improvement in CBT when clients rated the credibility of CBT as low or moderate. Expected engagement did not predict therapy completion in either therapy. Assessment of expected engagement could be a useful tool in prediction of symptomatic improvement in CBT.
Harrison, Richard L.	2020	Termination in 16-session accelerated experiential dynamic psychotherapy (AEDP): Together in how we say goodbye		57	4	This article explores key aspects of the termination process in a 16-session treatment protocol of accelerated experiential dynamic psychotherapy (AEDP). AEDP theory and its empirical support are described; interventions used throughout termination are demonstrated with verbatim clinical exchanges; and potential challenges faced during termination are addressed. Congruent with AEDP's healing orientation, termination is reframed as completion and launching: Although treatment ends, the change process begun in therapy can continue, as does the therapist's care for the patient. AEDP interventions during termination include (a) relational strategies to foster connection and undo aloneness; (b) the highlighting of patient resilience and the celebration of growth; (c) affirmative work with defenses around loss; (d) coregulation of patient's emotional experience; (e) experiential, bodily-rooted affective strategies to process and transform negative emotions; and (f) thorough exploration and processing of ensuing, vitalizing positive emotions and in-session experiences of change-for-the-better (i.e., metatherapeutic processing), to expand these and promote enhanced well-being and flourishing. Therapists aim to (a) elicit and process emotions related

							to the completion of treatment; (b) celebrate patients' affective achievements; and (c) convey trust and confidence in an ongoing transformational process, predicted to yield not only diminishment of symptoms and suffering but also upward spirals of flourishing. AEDP suggests that in providing patients a new, positive attachment experience of togetherness as therapy ends, termination offers a unique opportunity to disconfirm patients' earlier attachment-based expectations, revise inner working models, and help patients grow in self-confidence as they face, accept, and thrive in the wake of loss. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Hartley, Jessica N.; Holmqvist, Maxine	2023	“Learning with each other, about each other”: Interdisciplinary learning among genetic counseling students and clinical health psychology residents	J. Psychiatr. Ment. Health Nurs. (Journal of psychiatric and mental health nursing)	n/a	n/a		Abstract Interprofessional collaborative healthcare is known to improve provider satisfaction and retention, as well as patient safety and quality of care. The specific knowledge, skills, and attitudes required to work in these environments are best taught interprofessionally. Despite having considerable overlap in training, orientation, and populations served, it is rare for trainees from genetic counseling and clinical health psychology to interact and learn together. In 2017, we developed an innovative week-long clinical health psychology rotation for students in the University of Manitoba MSc in Genetic Counselling Program, which aims to enrich psychotherapeutic/counseling knowledge and skills, as well as gain familiarity with the work of clinical psychologists. This rotation incorporates didactic teaching, observation, and structured reflection. Didactic teaching includes topics such as psychological assessment, adaptation to life-altering news, skills for managing intense emotional responses, and counseling for change. Observations of clinical health psychologists

							and clinical health psychology residents occur in a range of health settings. Structured reflection is practiced in both oral and written formats. Finally, both groups of trainees participate in an interprofessional case seminar series. Feedback from this experience has been very promising, and it was identified as a strength in the program's accreditation review. Adaptations over time include refining the clinical exposures to increase breadth and relevance, increasing the contact between the trainees from the two professions and enhancing the case seminar series to be more learner-driven and to focus on explicit interprofessional skills and themes. In addition to expected results, this rotation has led to some unanticipated findings, including an emergent emphasis on the social determinants of health and the need to work collaboratively for systemic change. Further, psychology residents have identified that it benefits them to learn more about genetic counseling and expressed interest in potential reciprocal learning opportunities in genetics clinics.
Hartmann, Armin; Zeeck, Almut; Herzog, Wolfgang; Wild, Beate; Zwaan, Martina de; Herpertz, Stephan; Burgmer, Markus; Wietersheim, Joern von; Tagay, Sefik;	2016	The Intersession Process in Psychotherapy for Anorexia Nervosa: Characteristics and Relation to Outcome	J. Clin. Psychol. (Journal of clinical psychology)	72	9	861–879	Objective The ?inter session process? (ISP) is defined as therapy-related conscious thoughts, memories, and emotions that patients and therapists experience between psychotherapy sessions. It indicates how the participants process and use treatment. The main aim of this study is to describe the ISP characteristics of patients in outpatient treatment for anorexia nervosa (AN). An additional aim is to explore the relation between patients' ISP and treatment outcome. Method Patients taking part in a randomized controlled trial on outpatient psychotherapy for AN (ANTOP) filled in the Intersession Experience Questionnaire before each of the 40 psychotherapy sessions. Trajectories of different aspects

<p>Dinkel, Andreas; Löwe, Bernd; Resmark, Gaby; Orlinsky, David; Zipfel, Stephan</p>							<p>of the ISP were analyzed with growth curve models based on orthogonal polynomials and tested for differences between 3 outcome categories (recovery, partially recovered, full syndrome AN). Results Data from 108 cases were available for analysis. ISP facets showed diverse, mostly nonlinear, trajectories over the course of treatment. Less favorable outcomes were associated with higher levels of patients? experiencing negative emotions when recalling therapeutic dialogue, thinking about therapy during dreaming/drowsy states, and applying therapeutic learning (in the second half of treatment). Conclusions Findings confirm an overall relation between ISP and treatment outcome. In outpatient treatment in AN, patients with a less successful course seem to be more preoccupied with therapy and therapist between sessions. For the ISP facet ?applying therapeutic learning,? findings point to an optimal range dependent on treatment phase. Growth curve modeling is required to describe the nonlinear trajectories of ISP facets.</p>
<p>Hartmann, Ellen; Opaas, Marianne</p>	<p>2023</p>	<p>Convergence in a multi-method study between Rorschach and self-report data of traumatized refugees assessed before and after psychotherapy</p>	<p>Journal of clinical psychology</p>	<p>79</p>	<p>5</p>	<p>1357–1370</p>	<p>UNLABELLED Rorschach and self-report instruments represent methodologically different types of assessment, which together may yield incremental information about the test-taker. There is little evidence on whether and when results from these methods converge. OBJECTIVE To examine possible convergences between Rorschach trauma-related personality variables and self-reported variables. METHOD Before and after psychotherapy 22 traumatized adult refugee patients were assessed with the Rorschach Performance Assessment System (R-PAS), symptom</p>

						<p>checklists of posttraumatic stress, anxiety and depression, and a quality of life questionnaire. Correlational analyses between eight R-PAS variables and 10 self-reported variables were performed.</p> <p>RESULTS</p> <p>The findings showed inconsistent and nonsignificant correlations pretherapy. Posttherapy, however, all R-PAS variables except Complexity correlated positively with symptoms of mental disorder, and negatively with the quality of life variables, as predicted. The R-PAS variables Mutuality of Autonomy-Pathology, Poor Human Representation, Critical Content, and Form Quality-minus%, converged significantly with most of the self-reported variables, with medium to large correlations.</p> <p>CONCLUSION</p> <p>The finding of convergence only after psychotherapy, may tentatively suggest greater self-knowledge and internal consistency through the therapy experience, and increased trust and self-disclosure through the repeated meetings with the researchers. The findings represent a promising contribution to a cumulative validation process of convergence between Rorschach and self-report data.</p>
Harty, Erin	2023	"Embodying opposites"-A case illustration of Dance Movement Therapy as an additional intervention in the treatment of co-morbid Borderline	Journal of clinical psychology			<p>Dance Movement Therapy is gradually becoming recognized as a treatment option in Mental Health Care. However, the working mechanisms can be difficult to comprehend without experiential knowledge of this therapy form. This article aims to offer insight into the clinical application of Dance Movement Therapy for Sanne, a woman with a history of interpersonal relationship difficulties, problems with self-regulation, low self-efficacy and diagnosed with Borderline Personality Disorder and co-morbid Complex Post Traumatic Stress Disorder. This case illustration describes</p>

		Personality Disorder and Complex Post Traumatic Stress Disorder					treatment interventions during two months of bi-monthly Dance Movement Therapy as an additional treatment alongside weekly group therapy and bi-monthly individual Psychotherapy. Post treatment, Sanne demonstrates improvements in self-regulatory behavior, interpersonal relationships and self-efficacy as well as an experience she describes as being whole. This article highlights the implications for practitioners of embodied forms of therapy as well as multidisciplinary teams who wish to better understand how the use of opposites within Dance Movement Therapy may be used as an additional intervention for people with Borderline Personality Disorder and co-morbid complex Post Traumatic stress Disorder.
Hasenfratz, Karin; Moergeli, Hanspeter; Sprott, Haiko; Ljutow, André; Hefti, René; Rittmayer, Isabelle; Peng-Keller, Simon; Rufer, Michael	2021	Do Chronic Pain Patients Wish Spiritual Aspects to Be Integrated in Their Medical Treatment? A Cross-Sectional Study of Multiple Facilities	Frontiers in psychiatry	12		685158	Background: Chronic pain is a complex, multidimensional experience. Spirituality is hypothesized to impact pain experience in various ways. Nevertheless, the role that spirituality plays in multimodal pain therapy remains controversial and, to date, quantitative data on whether and for which patients spiritual aspects should be considered in the treatment of chronic pain is lacking. The aim of this study was thus to investigate the proportion and characteristics of patients with chronic pain who wish spiritual aspects to be integrated in their treatment. Methods: Two hundred nine patients with chronic pain were recruited from five inpatient departments and outpatient clinics in the German-speaking part of Switzerland. Patients filled out validated questionnaires, such as the Hospital Anxiety and Depression Scale (HADS), the Resilience Scale (RS-11), the Spiritual and Religious Attitudes in Dealing with Illness (SpREUK), and the 12-item Spiritual Well-Being Scale (FACIT-Sp-12). Results: More than 60% (CI(95%):

							55.5-67.9%) of the patients wanted to address spiritual aspects in their treatment. These patients were significantly younger, had higher levels of education, and suffered from more frequent and more severe pain than patients who did not wish to address spiritual aspects. Furthermore, there were high correlations with existing spiritual resources and higher scores of spirituality. Conclusions: These results confirm that the majority of chronic pain patients wish spiritual aspects to be considered in their treatment. Additionally, the finding that these patients had more spiritual resources underlines the importance of integrating spiritual aspects in a resource-oriented, patient-centered care approach for this condition.
Hasson-Ohayon, Ilanit; Cheli, Simone; Lysaker, Paul H.	2021	Emerging psychotherapeutic approaches to addressing self-experience in schizophrenia spectrum disorders	Journal of clinical psychology	77	8	1781–1785	Growing awareness that many who are diagnosed with schizophrenia recover has spurred the development of new psychosocial approaches to treatment. These new approaches include forms of individual and group psychotherapy whose focus extends beyond reducing symptoms and improving skills to subjective outcomes related to sense of self. This paper introduces an issue of In Session which presents six case reports which illustrating these approaches in differing international contexts. First, we explore the larger issues of subjective outcomes from schizophrenia. We then discuss each of the papers separately along with implications of these papers as a group for how treatment might promote the recapturing of a sense of self or place in the world.

Hauser, Reini; Heidelberg, Reiner; Weyermann, Ruth; Helbling, Josef; Goodbread, Joe; Hrtreiter, Sylvia; Apel, Claudia	2022	Prozessorientierte Psychotherapie. Einführung in Theorie, Methoden und Praxis					<p>Es wird eine Einführung in Theorie, Methoden und Praxis der prozessorientierten Psychotherapie nach Arnold Mindell gegeben. Die prozessorientierte Psychotherapie verbindet Analytische Psychologie und Systemdenken mit erfahrungsorientierter Praxis. Als humanistisch-experienzieller Ansatz werden mit wahrnehmungsbasierten Methoden die Potenziale in den Strungen selbst entfaltet - hin zur Erfahrung von Kohrenz und Sinnhaftigkeit. Von der Entwicklung der Prozessarbeit über ihre philosophische und methodentheoretische Verortung hin zum Arbeitsmodell wird Einsicht in Denken, Fühlen und Intervenieren prozessorientierter Praxis vermittelt. Psychiatrische Strungsbilder werden methodenspezifisch betrachtet und Prozessverläufe wie Interventionspraxis anhand von Beispielen erfahrbar gemacht. Über die Integration der prozessorientierten Gruppenpsychotherapie weitet sich der Blick vom individualpsychologischen Kontext auf systemische und feldtheoretische Wirkfaktoren im psychischen Selbst- und Welterleben. Der Forschungsstand zu Wirksamkeit und Therapieerfolg sowie Bedingungen für einen Transfer von der Theorie in die Praxis werden dargestellt.</p> <p>Prozessorientierte Methoden lassen sich anwenden in Psychotherapie, Medizin, psychosozialer Arbeit, Konfliktarbeit, Mediation, Gruppenleitung und Gruppenpsychotherapie. Fachpersonen erhalten hierfür praxistaugliche Haltungen und Werkzeuge, Studierende finden Grundlagen und eine übersichtliche Einführung. - Inhalt: </p>

Hautmann, Christopher; Dose, Christina; Hellmich, Martin; Scholz, Kristin; Katzmann, Josepha; Pinior, Julia; Gebauer, Stephanie; Nordmann, Lisa; Wolff Metternich-Kaizman, Tanja; Schürmann, Stephanie; Döpfner, Manfred	2023	Behavioural and nondirective parent training for children with externalising disorders: First steps towards personalised treatment recommendations	Behaviour research and therapy	163		104271	For children with externalising disorders, parent training programmes with different theoretical foundations are available. Currently, there is little knowledge concerning which programme should be recommended to a family based on their individual needs (e.g., single parenthood). The personalised advantage index (PAI) indicates the predicted treatment advantage of one treatment over another. The aim of the present study was to examine the usefulness of this score in providing individualised treatment recommendations. The analysis considered 110 parents (per-protocol sample) of children (4-11 years) with attention-deficit/hyperactivity (ADHD) or oppositional defiant disorder (ODD), randomised to either a behavioural or a nondirective telephone-assisted self-help parent training. In multiple moderator analyses with four different regression algorithms (linear, ridge, k-nearest neighbors, and tree), the linear model was preferred for computing the PAI. For ODD, families randomised to their PAI-predicted optimal intervention showed a treatment advantage of $d = 0.54$, 95% CI [0.17, 0.97]; for ADHD, the advantage was negligible at $d = 0.35$, 95% CI [-0.01, 0.78]. For children with conduct problems, it may be helpful if the PAI includes the treatment moderators single parent status and ODD baseline symptoms when providing personalised treatment recommendations for the selection of behavioural versus nondirective parent training. TRIAL REGISTRATION: The study was registered prospectively with ClinicalTrials.gov (Identifier NCT01350986).
Havighurst, Sophie S.;	2020	Emotion-focused	Current opinion in psychiatry	33	6	586–601	To review recent studies on emotion-focused parenting interventions to provide clinicians with knowledge about

Radovini, Alessandra; Hao, Brandon; Kehoe, Christiane E.		parenting interventions for prevention and treatment of child and adolescent mental health problems: a review of recent literature					how these approaches might be used in prevention and treatment of mental health difficulties for children, adolescents and their families. A number of emotion-focused parent interventions are reported in the literature, including emotion coaching/communication parenting programs, emotion-focused family therapy, attachment-focused parenting interventions (including those that address parental reflective functioning/mentalization), mindfulness parenting programs and behavioral programs with added emotion components. All target emotions or emotional communication to assist parents and children understand and work through emotional experiences so they are less likely to impede healthy functioning. These interventions target four main domains: exploring family of origin or early attachment/relational experiences with emotion, targeting parents' own emotion awareness and regulation, shifting parents responses to or communication with their children when emotions occur, and promoting parents' skills for assisting children to regulate emotions and behavior. This review from the last 18 months found 50 studies that evaluated programs addressing these domains. Whilst the dominant approach in evidence-based parenting programs has been teaching behavioral strategies, it has been recognized that a focus on emotion-related processes is important. This is especially when working to improve the attachment relationship or when parents and children experience emotion dysregulation. This review demonstrates extensive evidence to support emotion-focused parenting interventions.
Haw, Rebecca; Hartley,	2023	A systematic review and	The British journal of	62	2	392–410	BACKGROUND Self-harm is a major public health concern. Lifetime

<p>Samantha; Trelfa, Sarah; Taylor, Peter J.</p>		<p>meta-ethnography to explore people's experiences of psychotherapy for self-harm</p>	<p>clinical psychology</p>			<p>prevalence is high, and rates of self-harm are rising; however, available interventions do not benefit everyone, and engagement with therapy can be low. Qualitative accounts allow for a greater understanding of what is helpful to individuals. This study aimed to synthesize the experiences of interventions for self-harm, from participants who have participated in these themselves.</p> <p>METHODS</p> <p>Participants had self-harmed at least once and undergone an individual psychotherapeutic intervention for self-harm. Papers not written or translated to the English language were excluded. Four databases (Medline, CINAHL, Web of Science and PsycINFO) were systematically searched and each paper was assessed using the CASP quality appraisal tool. A meta-ethnographic approach to the synthesis was taken.</p> <p>RESULTS</p> <p>Ten studies encompassing 104 participants were included. Four overarching themes were developed and the importance of recognizing the person beyond the self-harm emerged through a line of argument synthesis. Building a trusted, therapeutic relationship founded on patience and without judgement was essential for the perceived success of therapy, which was unique to each person and often went beyond reducing self-harming behaviours.</p> <p>LIMITATIONS</p> <p>Papers included in the study showed a lack of diversity with regard to ethnicity and gender.</p> <p>CONCLUSIONS</p> <p>The findings illustrate the importance of the therapeutic alliance when working with self-harm. Clinical implications of this paper include the importance of</p>

							utilizing key therapeutic competencies which should be considered fundamental to change within psychotherapeutic interventions for self-harm, with the uniqueness of each patient recognized throughout.
Hawkins II, Raymond C.	2022	Measurement of dreams by SCORS and LIWC: Prelude to dreamwork in psychotherapy	Dreaming	32	1	52-62	Reliable and valid measures of dream content are necessary for evidence-based dreamwork in psychotherapy research. This article provides normative data on the Social Cognition and Object Relations Scale-Form L (SCORS-L) applied to normal college students' dreams. Concurrent computer text analysis of 630 college students' recent dreams and important dreams using the Linguistic Inquiry Word Count 2007 (LIWC 2007) was done to provide construct validation for the SCORS-L dream rating measure. SCORS-L affect and object relations content scales were significantly positively correlated with LIWC first person plural pronouns, social category words, and affiliation. SCORS-L scales involving cognitive content were significantly correlated with LIWC third person singular pronouns, social and family category words, and positive emotion words. SCORS-L ratings for important dreams were higher than for recent dreams for scales involving complexity of representations of people, the capacity for emotional investment in relationships, emotional investment in values and moral standards, understanding of social causality, and management of aggressive impulses. The SCORS-L rating scales for dreams show promise as a reliable, valid indicator of affective and object relational content that can supplement word search measures such as LIWC and the Hall/Van de Castle method. Hawley, Kathryn J.; Winter Plumb, Evelyn I.; Conoley, Collie W.	2020	Goal-focused positive psychotherapy in action: A case study	Journal of clinical psychology	76	7	1217–1225	<p>OBJECTIVE This case study describes one client's progression through goal-focused positive psychotherapy (GFPP), a positive psychology inspired treatment. The study aims to contribute a more nuanced understanding of GFPP by illustrating the clinical use of approach goals, hope, positive emotion, and client strengths-interventions that constitute the heart of GFPP.</p> <p>METHOD The case study methodology illuminates the 33-session treatment of a self-identified European-American heterosexual female in her mid-twenties, presenting with several interpersonal concerns, and symptoms of depression and anxiety. The client met the DSM 5 criteria for generalized anxiety disorder and borderline personality disorder.</p> <p>RESULTS Processes and outcomes are documented through clinician and client perceptions, and weekly assessments of symptomatology and subjective well-being.</p> <p>CONCLUSIONS The case study demonstrates a successful application of positive psychology consistent with GFPP's existential and humanistic psychology roots. The study should provide clinicians and theorists a greater understanding of GFPP processes and perspectives in an applied context.</p>
Hawranek, Pia; Kasper, Lea; Weigl, Melanie; Schramm, Elisabeth; Taubner, Svenja	2023	"I Think it's Good that they Choose who they want to be Stroked by" -The Support Quality	Praxis der Kinderpsychologie und Kinderpsychiatrie	72	8	702–721	For Adolescents with personality impairments it's often difficult to accept therapy offers. Personality impairment may be preceded by (early childhood) trauma, which undermines trust in others. Thus, adolescents with traumatic experience often have limited motivation to start psychotherapy, also due to the greater need for

		of Animal-Based Therapy					<p>autonomy and the process of detachment in this age phase. However, adolescence is a particularly sensitive period, as personality impairments may consolidate and personality disorders (PD) develop. To address low trust and low motivation in adolescents with high risk for or already full PD an animal-assisted group therapy adjunct to individual mentalization-based therapy was developed and piloted. Two groups with a total of eleven patients each were conducted, four of whom agreed to talk about their experiences with animal-assisted therapy in an interview after completion of therapy. Interviews were analyzed qualitatively and evaluated with regard to the aspects of what the adolescents liked and disliked, what expectations were met or unmet, and what effects the adjunct intervention had on the adolescents' therapeutic success. The categorized statements are discussed related to the theories of human-animal interaction according to Hediger et al. (2019) and a new hypothesis about animals as team building catalysts could be established. In sum, alpacas were perceived suitable as therapy animals for adolescents with personality impairments.</p>

Hazzard, Vivienne M.; Peterson, Carol	2020	Predictors of treatment response	The International	53	12	1918–1927	<p>OBJECTIVE To examine changes in hypothesized maintenance mechanisms during treatment as predictors of treatment</p>

<p>B.; Crosby, Ross D.; Schaefer, Lauren M.; Smith, Kathryn E.; Engel, Scott G.; Crow, Scott J.; Wonderlich, Stephen A.</p>		<p>durability in psychotherapy for binge-eating disorder: Examining the roles of self-discrepancy, self-directed style, and emotion dysregulation</p>	<p>journal of eating disorders</p>			<p>response durability in binge-eating disorder (BED) treatment, using data from a randomized clinical trial comparing the efficacy of Integrative Cognitive-Affective Therapy for BED with cognitive-behavioral therapy delivered using guided self-help.</p> <p>METHOD Adults with BED (N = 112) received 17 weeks of treatment. Regression models were conducted to examine the extent to which changes in hypothesized maintenance mechanisms from baseline to end of treatment predicted treatment outcomes at 6-month follow-up, adjusting for demographics, study site, and baseline level of treatment outcome.</p> <p>RESULTS During-treatment reductions in negative self-directed style and emotion dysregulation predicted reductions in the primary treatment outcome (i.e., binge-eating episode frequency) at follow-up. During-treatment reductions in emotion dysregulation also predicted improvements at follow-up across all three secondary treatment outcomes examined (i.e., global eating disorder [ED] psychopathology, depressive symptoms, and anxiety symptoms), as did during-treatment reductions in actual-ideal self-discrepancy and actual-ought self-discrepancy. Increases in positive self-directed style (e.g., self-affirmation) and reductions in negative self-directed style (e.g., self-blame) during treatment each predicted improvements in anxiety symptoms at follow-up. When predictors were examined simultaneously, the most salient predictors of treatment response durability identified were negative self-directed style for binge-eating episode frequency, actual-ought self-discrepancy and emotion dysregulation for depressive symptoms, and</p>
---	--	---	------------------------------------	--	--	--

							emotion dysregulation for anxiety symptoms. No predictors emerged as most salient for global ED psychopathology. DISCUSSION Results indicate that negative self-directed style and emotion dysregulation are particularly important treatment targets in relation to behavioral treatment outcomes in BED.

Heberle, Amy E.; Hoch, Noah; Wagner, Anna C.; Caccia Cruz, Amanda G.; Zhou, Longjing; Khan, Aiman K.	2023	Examining feasibility, acceptability, and participant experiences of an anti-racist parenting intervention for White U.S. parents	American Journal of Orthopsychiatry			No Paginatio n Specified -No Paginatio n Specified	Many White parents engage in minimal discussion of race and racism with their children, instead engaging in color-evasive practices that communicate that race is unimportant and that White people are racially neutral. Even White parents who express a commitment to anti-racist parenting frequently struggle to act on this commitment and feel underprepared to do so. The current mixed methods pilot study focused on the feasibility, acceptability, and participant experiences of an intervention (“CounterACT”) that aimed to address this gap in White U.S.-based parents’ skills and knowledge. Participants in the study were 27 White U.S.-based parents of 4- to 6-year-old White children who completed pre- and postintervention surveys as well as postintervention interviews. Findings suggest that the CounterACT model was feasible and acceptable. Parent self-report further suggests that CounterACT had beneficial effects on parenting, parents’ beliefs regarding White privilege, and children’s critical reflection. Parents reported positive experiences of CounterACT, particularly group components of the intervention. Key elements of

							<p>participants' experience included learning to understand their own and their children's experience of Whiteness; learning to better tolerate and regulate emotional discomfort; connecting with others for motivation, accountability, and learning; and approaching racial socialization with greater intentionality. However, parents also experienced limits in their progress toward anti-racist parenting. Many indicated a desire for more concrete guidance and greater support enacting what they were learning in their own parenting. A particular concern was how to discuss White racial identities effectively. Our discussion highlights the implications of these findings for future work in this area. <p>Hebert, Catherine A.; Hancock, Kathryn; McConnell, Eleanor S.</p>	<p>2018</p>	<p>Implementation of Individualized Music in Long-Term Care: Application of the PARIHS Framework</p>	<p>Journal of gerontological nursing</p>	<p>44</p>	<p>8</p>	<p>29–38</p>	<p>The need to provide evidence-based, person-centered care for long-term care (LTC) residents, which often include individuals with dementia, has led to a surge of interest in the implementation of individualized music (IM) programs. An exploratory study was conducted over a 6-month period using the Promoting Action on Research in Health Systems (PARIHS) framework to examine the implementation of an IM program with 19 residents in a LTC facility. All residents using IM had the device available at the end of the program, and 53% received IM at least two times per week. Qualitative analysis of stakeholder interviews with six staff members and three residents after using the PARIHS framework as an implementation guide revealed two themes: Overcoming Resistance to Innovation and Person-Centered Care Through IM. Identification of barriers and facilitators through the PARIHS elements of evidence, context, and facilitation supported the IM implementation process and should</p>

							enable its replication in other facilities. [Journal of Gerontological Nursing, 44(8), 29-38.].

Heer, Sara; Stähli, Annabarbara;	2022	How do novice therapists manage the	Journal of Psychotherapy Integration	32	2	225–241	Integration of different psychotherapeutic approaches and interventions has become a crucial aspect in psychotherapy practice. Although different conceptual

Edöcs, Judit; Suppiger, Elvira; grosse Holtforth, Martin; Babl, Anna; Lin, Mu; Berger, Thomas; Caspar, Franz		process of assimilative integration? A qualitative interview study about the application of implicit heuristics				models exist, the experiences of integrative therapists are often ignored. The aim of the present study is to reach a better understanding of therapists' experiences and challenges while integrating new therapy elements. Twenty-six relatively inexperienced therapists took part in the interview study, which was embedded in a randomized control trial. The goal was to carry out 3 psychotherapies while integrating either components of Emotion-Focused Therapy (EFT) or Self-Regulation (SR) into their treatment as usual. Therapists were interviewed during 3 different time points throughout their therapies. In total, 97 interviews were transcribed and analyzed using MAXQDA 12.3 following Mayring's (2000) qualitative content analysis. Results indicate that therapists implicitly followed heuristics to assimilate new therapy elements into their originally trained approach. With the integration of therapy elements from conceptually more foreign therapy orientations (i.e., EFT), therapists seemed to experience a slightly higher challenge, but at the same time, perceived it as a chance to enrich their practice with the result of a more individualized, responsive practice. 62% of all therapists reported a thorough change in their therapeutic style. The results suggest that assimilative integration is a complex, multidimensional process guided by various principles regarding the fit of the new therapy elements to patients and therapist characteristics in a responsive manner considering the therapeutic alliance. The findings stress the importance of therapists' relational flexibility. (PsyInfo Database Record (c) 2022 APA, all rights reserved)
Heim, Stefan; Polyak, Stella; Humann, Katja	2022	Mimicking effects of auditory verbal	Frontiers in Psychology, 2022			Schizophrenia is characterised foremost by hallucinations, delusions and disorganised speech. Deficits in the internal speech monitor may contribute to

		hallucinations on language production at the level of words, sentences and stories					the development of auditory-verbal hallucinations. This study investigates potential effects in the opposite direction: could the presence of auditory-verbal hallucinations have an effect on speech production? To this end, a recent mimicking/simulation approach was adopted for 40 healthy participants who perceived either white noise or hallucination-like speech recordings during different language production tasks with increasing demands: picture naming, verbal fluency with and without category switch, sentence production, and discourse. In line with reports about real schizophrenia cases in the literature, mimicking auditory-verbal hallucinations affected verbal fluency (switch condition) and sentence production (duration) in a different way than mere noise. These effects were not correlated, suggesting that hallucinations may even affect different levels of linguistic complexity in different ways. Anyway, in both cases (mimicked), auditory hallucination appear to contribute to the emergence of disordered speech. The mimicking/simulation paradigm may in future help to identify and disentangle the various factors contributing to disorganised speech in schizophrenia. They may also support the development and implementation of new protocols, e.g., in speech and language therapy in persons with schizophrenia in order to improve their communication skills despite the presence of auditory-verbal hallucinations.

Heinonen, Erkki; Pos, Alberta E.	2020	The role of pre-treatment interpersonal problems for in-session emotional processing and long-term outcome in emotion-focused psychotherapy	Psychotherapy research: journal of the Society for Psychotherapy Research	30	5	635–649	Objective: Interpersonal problems may lead to, uphold, or follow from depression. However, we know little of how depressed patients' different interpersonal problems are associated with patients' emotional processing during psychotherapy and whether distinct processes are helpful for their long-term reduction. Method: 23 adult outpatients who received emotion-focused therapies lasting 16-20 sessions filled the Inventory of Interpersonal Problems at pre- and post-treatment and 18-month follow-up. These problems were related to emotional processing in two mid-therapy sessions, rated by observers with the Classification of Affective-Meaning States. Results: All pre-treatment interpersonal problems were clearly associated with patients' negative evaluations of themselves during therapy. Self-experiences of vindictiveness were most pronouncedly linked to in-session emotional expressions of rejecting anger, and self-experiences of social inhibition to expressions of fear and shame, following a circumplex model. In the long-term reduction of interpersonal problems, especially reaching emotional states of hurt and grief seemed beneficial for patients who experienced themselves as socially inhibited, non-assertive, self-sacrificing, or overly accommodating. Conclusions: For clients suffering from particular interpersonal problems, accessing particularly beneficial emotional processes, such as hurt and grief, may form specific therapeutic process goals. Further studies should verify these

							findings, which link interpersonal theory with research on emotional processing in psychotherapy.

Heled, Eyal	2021	The Trajectory of Adaptation: A Review of Psychoanalytic Conceptualization of the Working Through and	Brit J Psychotherapy (British Journal of Psychotherapy)	37	3	417–438	Disability is a long-term physically or mentally, limiting condition that significantly impacts various life domains. It is associated with a trajectory of emotional adaptation that encompasses diverse internal and external processes. Though rare, psychoanalytic views on adaptation to and acceptance of disability have been proposed, with potential value for rehabilitation. Freud's relatively brief contributions to this field inspired later theorists to elaborate on his concepts and adjust them to

		Acceptance of Disability					<p>address the phenomenology of disability. The majority of these theorists focused on ego and self formulations, while taking external reality into account.</p> <p>Psychopathology in disability was also addressed, as well as acceptance as a primary goal of adaptation. Authors have emphasized the uncertainty of acceptance, highlighting the importance of attunement to individual patient needs and suggesting that psychoanalytic formulation can help psychotherapists to better understand and treat individuals with disability. The meanings and implications of the various conceptualizations are integrated and illustrated through a case example.</p>
Helle, Mark	2022	Gesprchspychotherapie in Deutschland. Vom Hhenflug zum Abstieg?. Erklrungsversuche	Person	26	2	95-101	<p>In diesem Beitrag wird der Frage nachgegangen, wie es dazu kommen konnte, dass die Gesprchspychotherapie in Deutschland so sehr an Bedeutung verloren hat. Zunchst wird in groben Zgen die Entwicklung der Gesprchspychotherapie im Kontext der hochschulpolitischen Vernderungen dargestellt. Anhand von drei Thesen wird dann herausgearbeitet, dass (1) die Gesprchspychotherapie kontrr zu den Professionalisierungsbestrebungen der Psychotherapie im Allgemeinen steht, (2) es ihr nicht gelungen ist, sich konstruktiv mit dem medizinischen Strungsverstndnis auseinanderzusetzen und (3) sie sich zu wenig flexibel zeigte, neuere Entwicklungen zu integrieren. Im Ergebnis zeigt sich, dass der aktuelle Status der Gesprchspychotherapie in Deutschland nicht nur auf fragwrddige Kriterien der wissenschaftlichen Anerkennung und der Beurteilung der Versorgungsrelevanz durch den wissenschaftlichen Beirat bzw. Gemeinsamen Bundesausschuss zurckzufhren ist, sondern auch auf</p>

		a meta-narrative review					
Hempeler, Christin; Gather, Jakob; Haberstroh, Julia; Trachsel, Manuel	2022	Shared Decision-Making for Patients with Mental Disorders or Cognitive Impairments	Therapeutische Umschau. Revue therapeutique	79	8	393–400	Shared Decision-Making for Patients with Mental Disorders or Cognitive Impairments Abstract. Shared Decision-Making (SDM) describes a model of collaborative decision-making that combines the expert knowledge of health professionals and the experiential knowledge of patients. This allows patients to play a more active role in the decision-making process. SDM is also becoming increasingly important in the treatment of persons with mental disorders or cognitive impairments. However, implementation of SDM for this group of patients may face specific challenges, for example, if their decision-making capacity is impaired or if coercion has to be used to prevent acute danger to themselves or others. On the other hand, SDM offers important opportunities in this area. For example, mental health professionals are often more dependent on the patients' experiential knowledge in clinical decision-making than in somatic care. Furthermore, empowerment and a good therapeutic relationship are central aspects in the treatment of people with mental disorders or cognitive impairments, which can be strengthened by SDM. Against the background of these specific challenges, an overview of opportunities for and experiences with SDM in the care of people with mental disorders or cognitive impairments is given. In addition, different approaches for promoting the implementation of SDM for this patient group will be identified.
Henker, Jana; Keller, Andrea; Reiss, Neele; Siepmann,	2019	Early maladaptive schemas in patients with	Clinical psychology & psychotherapy	26	4	418–429	Abstract Maladaptive schemas are stable relational patterns that develop through harmful childhood experiences with primary caregivers. Schemas within somatoform disorders are rarely explored even though

Martin; Croy, Ilona; Weidner, Kerstin		somatoform disorders and somatization				these disorders are clinically important due to high prevalence, co-morbidity, and cost for the health care system. This study investigates schemas according to Young's schema theory in patients with somatoform disorders in comparison with healthy controls and patients with depressive or anxiety disorders. Further associations between schemas and somatization were explored. We included 134 patients with a somatoform disorder and 39 age-matched healthy controls, 83 patients with a unipolar depression, and 34 patients with an anxiety disorder. The clinical sample consists of day care patients, diagnosed with the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, but without a personality disorder. Primary measures were the Young Schema Questionnaire (YSQ-S2), the Screening for Somatoform Disorders (SOMS-7T), the Beck Depression Inventory, Second Edition, and the Childhood Trauma Questionnaire. Analyses of variance indicated that somatoform patients scored higher on almost all schemas than do healthy controls ($p < 0.001$, $\eta^2 = 0.148$). The highest mean scores were reached for the schemas 'self-sacrifice' and 'unrelenting standards,' with significant higher values in the patient sample. However, when compared with patients with depressive or anxiety disorders, somatoform patients scored equally or even lower. High somatization was associated with generally higher schema activation. This effect was to a great extent mediated by depressive symptoms. Only the schema 'vulnerability to harm or illness' was exclusively related to somatization. These findings suggest that schemas should be systematically assessed within psychotherapy of somatoform patients.

Hennemann, Severin; Witthöft, Michael; Bethge, Matthias; Spanier, Katja; Beutel, Manfred E.; Zwerenz, Rüdiger	2018	Acceptance and barriers to access of occupational e-mental health: cross-sectional findings from a health-risk population of employees	International archives of occupational and environmental health	91	3	305–316	<p>PURPOSE: Occupational e-mental-health (OEMH) may extend existing instruments for preservation or restoration of health and work ability. As a key precondition to efficient implementation, this study examined acceptance and person-centered barriers to potential uptake of OEMH for work-related distress in employees with an elevated risk of early retirement. METHODS: Within the framework of the "Third German Sociomedical Panel of Employees", 1829 employees with prior sickness absence payments filled out a self-administered questionnaire. Participants had a mean age of 49.93 years (SD = 4.06). 6.2% indicated prior use of eHealth interventions. Potential predictors of acceptance of OEMH were examined based on the "Unified Theory of Acceptance and Use of Technology" (UTAUT) extended by work ability, mental health, eHealth literacy and demographic characteristics. RESULTS: 89.1% (n = 1579) showed low to moderate acceptance (M = 2.20, SD = 1.05, range 1-5). A path analysis revealed significant, positive direct effects of UTAUT predictors on acceptance (performance expectancy: 0.48, SE = 0.02, p < 0.001; effort expectancy: 0.20, SE = 0.02, p < 0.001; social influence: 0.28, SE = 0.02, p < 0.001). Online time and frequency of online health information search were further positive direct predictors of acceptance. Model fit was good [$\chi^2(7) = 12.91$, p = 0.07, RMSEA = 0.02, CFI = 1.00, TLI = 0.99, SRMR = 0.01]. CONCLUSIONS: Attitudes towards OEMH are rather disadvantageous in the studied risk group. Implementation of OEMH, therefore, requires a-priori education including promotion of awareness, favorable attitudes regarding efficacy and usability in a collaborative approach.</p>

<p>Hente, Elizabeth; Sears, Richard; Cotton, Sian; Pallerla, Harini; Siracusa, Christopher; Filigno, Stephanie Spear; Boat, Thomas</p>	<p>2020</p>	<p>A Pilot Study of Mindfulness-Based Cognitive Therapy to Improve Well-Being for Health Professionals Providing Chronic Disease Care</p>	<p>The Journal of pediatrics</p>	<p>224</p>		<p>87-93.e1</p>	<p>OBJECTIVE: To assess the efficacy of mindfulness-based cognitive therapy delivered onsite during work hours in reducing stress and improving well-being in an interdisciplinary chronic care health care team. STUDY DESIGN: A longitudinal, mixed methods, observational pilot study using a survey created from validated assessment tools to measure effectiveness of training. Surveys were completed before training, and 1 and 15 months after training. Twenty-four professionals in the cystic fibrosis Centers at Cincinnati Children's Hospital and the University of Cincinnati participated in 6 mindfulness-based cognitive therapy training sessions. Sessions incorporated mindfulness, cognitive therapy, and experiential exercises for processing feelings related to stress and burnout. RESULTS: The presurvey and 1-month postsurvey responses revealed statistically significant improvements for empathy, perceived stress, depersonalization, anxiety, perspective taking, resilience, and negative affect. Sustained effects were seen at 15 months for empathy, perspective taking, and depressive symptoms. The 1-month post-training surveys reported a quarter of respondents (25%) practiced skills at least 5 times in between sessions; at 15 months, 35% reported practicing at the same frequency. Participants reported using mindfulness skills for personal stressful events (74%), work-related general stress (65%), patient-related stress (30%), sleep or general relaxation (22%), and wellness (13%). CONCLUSIONS: Group mindfulness-based cognitive therapy training was feasible and effective in decreasing stress for interdisciplinary cystic fibrosis care team members who elected to participate. Further investigation is needed to determine optimal dose of training, durability of perceived benefits, and</p>

							generalizability to health care professionals working with other chronic disorders.
Hentschel, Gebhard; Winter, Elena	2020	"Der Goldstandard der ambulanten Psychotherapie ist der persönliche Kontakt"	Gesprächspsychotherapie und Personenzentrierte Beratung	51	3	14-15	Welche Auswirkungen könnte die Coronakrise auf die Psychotherapie haben? Und welche Zukunft haben insbesondere psychotherapeutische Angebote per Video? Gebhard Hentschel, Bundesvorsitzender der Deutschen Psychotherapeutenvereinigung (DPtV), gibt im Interview eine erste Einschätzung.
Hereford, McKenna; Wilcox, Melanie M.; Pollard, Elinita	2023	A phenomenological exploration into therapists' multicultural case conceptualizations	Journal of Psychotherapy Integration	33	3		Scholars have long emphasized the importance of cultural responsiveness in therapy; however, the evidence for the multicultural competence (MCC) model is mixed, and most extant research is quantitative in nature. The purpose of this phenomenological study was to gather insight into what therapists focus on during conceptualization without prompting for multicultural information. We conducted a qualitative study to examine therapists' multicultural case conceptualization and diagnosis to better understand therapists' cultural processes. The research questions were: What do therapists attend to in case conceptualization, and how does it influence diagnosis? How do these diagnoses influence intervention? Semistructured interviews were conducted with seven White practicing psychotherapists who were asked to provide a case conceptualization in response to a vignette. Participants' interview data (inclusive of their case conceptualization and answers about their thought processes) was analyzed, and six themes emerged: MCC, systems of support, controlling images, biological factors, multicultural orientation, and focus on cognitive therapies. Implications and future directions are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)

Hermann, Nina	2021	Das Sprachenportr. Ein Instrumentarium in der Arbeit mit traumatisierten geflüchteten Menschen	Person	25	1	44–53	Sprache nimmt in der psychotherapeutischen Arbeit mit traumatisierten geflüchteten Menschen oft eine zentrale Rolle ein: sei es, dass die Betroffenen keine Worte für das erlebte Grauen finden können - Stichwort "speechless terror" - sei es, dass sie die Sprache des Aufnahmelandes nicht beherrschen, also sprachliche Barrieren im Weg stehen. Besonderheiten wie die Auseinandersetzung mit fremden Kulturen, der oft unverzichtbare Einsatz von Dolmetscher*innen und das Ausmaß der Traumatisierung durch menschen- verursachte Gräueltaten wie Krieg, Verfolgung und Folter müssen Berücksichtigung finden. Der Personenzentrierte Ansatz stellt die tragfähige Beziehung zwischen Klient*in und Therapeut*in in den Mittelpunkt von Therapie und Beratung. Das sogenannte Sprachenporträt, welches in diesem Artikel vorgestellt wird, kann als wertvolles Instrument dienen, betroffene Personen bei der Wiedererlangung von Kontrolle und Selbstbestimmung zu unterstützen und ihre Einzigartigkeit zu würdigen, welche oft durch ihre persönliche Sprachenvielfalt Ausdruck findet.
Hernandez, Morela; Avery, Derek R.; Tonidandel, Scott; Hebl, Mikki R.; Smith, Alexis N.; McKay, Patrick F.	2016	The role of proximal social contexts: Assessing stigma-by-association effects on leader appraisals	Journal of Applied Psychology	101	1	68–85	Prior research suggests that segregation in the U.S. workplace is on the rise (Hellerstein, Neumark, & McInerney, 2008); as such, leaders are more likely to lead groups of followers composed primarily of their own race (Elliot & Smith, 2001; Smith & Elliott, 2002). Drawing from theory on stigma-by-association, the authors posit that such segregated proximal social contexts (i.e., the leader's group of followers) can have detrimental effects on leader appraisals. Specifically, they argue that leaders of mostly Black follower groups experience stigmatization based on race stereotypic beliefs, which affects how they are viewed in the eyes of observers. The results of a large field study show performance evaluations generally tend

						to be lower when the proportion of Black followers is higher. Moreover, 3 experiments demonstrate that the impact of proximal social contexts extends to other outcomes (i.e., perceptions of market value and competency) but appears limited to those who are less internally and externally motivated to control their prejudice. Taken together, these findings explain how workplace segregation systematically can create a particular disadvantage for Black leaders. (PsycINFO Database Record (c) 2016 APA, all rights reserved)
Herres, Joanna; James, Kiera M.; Bounoua, Nadia; Krauthamer Ewing, E. Stephanie; Kobak, Roger; Diamond, Guy S.		Anxiety-related difficulties in goal-directed behavior predict worse treatment outcome among adolescents treated for suicidal ideation and depressive symptoms	Psychotherapy	58	4	Although treatments for youth at risk for suicide have been successful, they are not similarly effective for everyone. Anxiety may interfere with adolescents' ability to engage with therapy and explain why some adolescents do not respond as well as others to treatment. The current study tested whether an anxiety diagnosis predicted treatment outcome among a sample of adolescents with suicidal ideation and depressive symptoms participating in either attachment-based family therapy or family-enhanced nondirective supportive therapy (N = 129; M age = 14.87, SD = 1.68; 81.9% female). The data set that the current study used had a high representation of Black/African American adolescents (48.8% of sample), which is valuable, as few studies have included adequate representation of this population. A significant indirect effect (.88; 95% confidence interval [.01, 2.64]) showed that across both treatment conditions, participants who met criteria for an anxiety disorder had greater difficulties engaging in goal-directed behavior midtreatment, and these difficulties, in turn, predicted more posttreatment suicidal ideation. The effect of anxiety on treatment outcome via difficulties with goal-directed behavior was nonspecific to the

							<p>treatment condition. However, attachment-based family therapy was superior to family-enhanced nondirective supportive therapy in improving this aspect of emotion regulation among adolescents who did not have anxiety. In addition, difficulties with goal-directed behavior on treatment outcome were worse for adolescents' who reported greater attachment avoidance to their parents. Future research should test whether targeting goal-directed behavior and attachment avoidance would result in better treatment outcome for adolescents with suicidal ideation and anxiety. (PsycInfo Database Record (c) 2022 APA, all rights reserved)</p>
Herrmann, Imke R.; Auszra, Lars	2021	Emotionsfokussierte Therapie					<p>Die Emotionsfokussierte Therapie (EFT) wird vorgestellt. Die EFT ist ein transdiagnostisches Verfahren, das bei einem breiten Spektrum an psychischen Strungen Anwendung finden kann. Wirksamkeitsnachweise liegen insbesondere fr die Behandlung von Depressionen und Traumafolgestrungen vor. Neben der emotionsfokussierten Theorie und Beziehungsgestaltung werden die zentralen emotionsfokussierten Interventionen erlutert. Psychischen Problemen und Symptomen liegen hufig Schwierigkeiten in der emotionalen Verarbeitung zugrunde. Die EFT zielt auf die Vernderung dieser Schwierigkeiten und rckt das emotionale Erleben von Patientinnen und Patienten und ihren Umgang mit diesem Erleben in den Mittelpunkt therapeutischen Handelns. Die EFT zeigt Wege auf, wie Patientinnen und Patienten ihre Emotionen adquat verarbeiten und flexibel zur Lsung aktueller Probleme nutzen knnen. Es geht darum, maladaptive Emotionen nachhaltig zu verndern und einen funktionaleren Umgang mit Emotionen zu frdern. Anhand von zahlreichen Beispielen und Therapiedialogen wird das therapeutische</p>

Herrmann, Imke R.; Greenberg, Leslie S.; Auszra, Lars	2016	Emotion categories and patterns of change in experiential therapy for depression	Psychotherapy Research	26	2	178-195	<p>Objective: This investigation examined the relationship between in-session types of emotional experience operationalized by the Emotion Category Coding System and the reduction of depressive symptoms in emotion-focused therapy (EFT). Method: Segments of videotaped sessions were coded and the different emotion categories were related to reduction in depressive symptoms in a sample of 30 clients who received EFT for depression. Results: Both fewer secondary and more primary adaptive emotions, in the working phases of therapy, were found to significantly predict outcome. Moderate levels of primary maladaptive emotion in the</p>

							middle working session were associated with outcome and the frequency with which clients moved from primary maladaptive to primary adaptive emotions in this session-predicted outcome. Conclusions: Results of this study support a transformational model of changing emotion with emotion.
Herrmann, Imke; Greenberg, Leslie; Auszra, Lars	2018	Arbeit mit Emotionen - Emotionsfokussierte Therapie					Emotionen wohnt ein funktionales adaptives Potenzial inne, das uns hilft, zu berleben und erfolgreich zu sein. Fr diese Annahme gibt es mittlerweile eine Flle empirischer Belege. Emotionale Schemata basieren auf angeborenen emotionalen Reaktionen, die sich mit Lernerfahrungen zu komplexeren inneren Organisationseinheiten verbinden. Aus Sicht einer Theorie der Verarbeitung, die auf emotionalen Schemata basiert, sind Menschen stndig im Begriff, eingehende sensorische Reize (aus dem Inneren des Krpers oder aus der Umwelt) auf Basis von Erfahrungen zu interpretieren, zu transformieren und aus ihnen Bedeutung abzuleiten. Diese Sinneswahrnehmungen werden ausgewertet und mit anderen Sinneswahrnehmungen verknüpft, wodurch sich ein bergeordnetes Bedeutungsschema ausbildet. Diese Zusammenhnge sind Thema des Kapitels. Herrmann-Lingen, C.	2018	Chronic heart failure and depression	Der Internist	59	5	445-452	BACKGROUND: Depression is a frequent comorbidity in chronic heart failure. It can be triggered by the experience of suffering from heart disease, but it can also play a causal role in accelerated development and poor prognosis of heart failure. OBJECTIVES: The aim of this study was to investigate the interrelationships between heart failure and depression and the psychophysiological and behavioral mechanisms involved in this association. The effects of comorbid depression on quality of life in patients with heart failure were also examined and

							<p>therapeutic options reviewed. METHODS: A narrative review of the literature was undertaken. RESULTS: Several psychophysiological and behavioral mechanisms have been identified as mediators of the association between depression and heart failure and the adverse prognostic effects of this comorbidity. Comorbid depression leads to substantial reductions in health-related quality of life. These effects are only incompletely antagonized by exercise training and cognitive behavioral therapy. No specific effect of antidepressant medication has been demonstrated as yet in patients with heart failure. DISCUSSION: While current guidelines recommend the identification and treatment of depressive comorbidity in patients with heart failure, the available evidence provides no convincing rationale for specific treatment recommendations beyond the guideline-based treatment of heart failure itself, lifestyle interventions and patient-centered medical care. If available, psychotherapy should be offered, ideally cognitive behavioral therapy. For patients that do not improve sufficiently under outpatient treatment, the German health care system offers dedicated psychocardiological inpatient treatment programs.</p>
Herron, Elizabeth K.; Powers, Kelly; Mullen, Lauren; Burkhart, Brandi	2019	Effect of case study versus video simulation on nursing students' satisfaction, self-confidence, and knowledge: A quasi-	Nurse education today	79		129-134	<p>BACKGROUND Research on simulation in nursing education has demonstrated the positive impact active, experiential learning has on student satisfaction, self-confidence, and knowledge. As a result, simulation laboratories with high-fidelity human patient simulators have become a common adjunct to clinical teaching. It is important to also promote active learning in the classroom setting; however, there is limited evidence on using video simulations in large classrooms.</p>

		<p>experimental study</p>				<p>OBJECTIVES This study sought to determine if using a video simulated unfolding case study as part of the didactic classroom, as compared to a traditional written case study, improved students' satisfaction, self-confidence, and knowledge.</p> <p>DESIGN A two-group, quasi-experimental design was used.</p> <p>SETTINGS The study occurred at a University in the southeastern United States.</p> <p>PARTICIPANTS A total of 165 baccalaureate nursing students participated.</p> <p>METHODS The control group received a written case study, while the intervention group received video simulation of the same case study and student satisfaction, self-confidence, and knowledge were measured upon completion. Data analysis used descriptive statistics and t-tests. Qualitative comments were also provided by students and analyzed for themes.</p> <p>RESULTS There were no statistically significant differences, with both groups reporting a high level of satisfaction and self-confidence. The percent of knowledge questions answered correctly was higher for the video simulation group for all seven questions. Four themes were identified from participant words: A better understanding, Able to apply learning to a patient scenario, Engaged in learning, and Visualizing it helps.</p> <p>CONCLUSIONS Results suggest the use of video simulation in the classroom may deepen students' understanding of</p>
--	--	---------------------------	--	--	--	---

							classroom content and provide an additional mode for learning to enhance classroom lecture. Use of video simulation to augment classroom teaching is suggested as a strategy for engaging learners.
Hersche, Ruth; Weise, Andrea	2022	Occupational Therapy-Based Energy Management Education in People with Post-COVID-19 Condition- Related Fatigue: Results from a Focus Group Discussion	Occupational therapy international	2022		4590154	Persons with post-COVID-19 conditions have prolonged symptoms and longer-term consequences which can prevent them from returning to previous everyday functioning. Fatigue is the most frequent symptom reported in literature. Occupational therapists (OTs) are specialized in client-centered problem analysis, counseling, and education to recover occupational engagement and performance in everyday life. Since the beginning of the COVID-19 pandemic, OTs have been challenged to respond with services adequate to the needs of this patient group. Energy management education (EME) was initially developed for persons with multiple sclerosis-related fatigue and then made independent of diagnosis suitable to persons living with chronic disease-related fatigue. EME, a structured self-management education, is becoming a part of the new services. This study was aimed at exploring the initial experiences of OTs using the EME protocol and materials with persons with postacute COVID-19 and/or post-COVID-19 condition-related fatigue and gathering their recommendations for improvements and adaptations. One online focus group discussion took place in May 2021 with OTs experienced in using the EME protocol. The topics addressed were the institutional context of the OTs and their experiences during the treatment. A thematic analysis was performed. According to nine OTs working in different settings in Switzerland, the EME protocol is exploitable in both in- and outpatient settings and was judged appropriate by them, even if the EME materials

							can be improved. The main challenges for the OTs were the short period their patients had lived with fatigue; the discrepancy between self-concept, self-perception, and performance; and the insecurity, fear, and anxiety related to recovery. Further research is needed to include the perspective of EME participants and to measure quantitative outcomes such as fatigue impact, self-efficacy, occupational performance, and quality of life. Until the existing EME protocol is improved, it is applicable to persons with post-COVID-19 condition-related fatigue.
Herulf Scholander, Lisa; Boström, Anne-Marie; Josephsson, Staffan; Vikström, Sofia	2023	Engaging in narrative relations in everyday work on a geriatric ward: A qualitative study with healthcare professionals	Journal of clinical nursing	32	13-14	3954–3966	AIMS AND OBJECTIVES: To explore healthcare professionals' experiences and reflections about narration in their everyday work. BACKGROUND: The need for integrated and people-centred healthcare for older adults has highlighted the relevance of narration in healthcare practice. Although theoretical foundations vary, different frameworks building on narration have been proposed for translating person-centredness philosophies into practice. However, to understand how theoretical knowledge on narration can be adopted into clinical work, we need to learn how healthcare staff understand narration from their experiential knowledge and practice. DESIGN: The research process followed guidelines from Constructivist Grounded Theory as described by Charmaz. The study adheres to the COREQ guidelines. METHODS: Data collection entailed interprofessional focus groups discussions with healthcare staff (n = 31). Vignettes depicting realistic scenarios were used to encourage participants to reflect on clinical practice. Data were analysed via a constant comparative method. RESULTS: One core theme arose from the analysis. The core theme showed how narration

							<p>was a relational process that people engaged in to pursue and uphold several foundational qualities in healthcare practice presented in the following subthemes: preventing simplistic understandings of people and situations; supporting trustful relations; supporting continuity and coherence; and learning from coworkers. However, a minor theme raised awareness of narrative relations as a double-edged sword. CONCLUSIONS: By acknowledging the mutual and multifaceted nature of narration in everyday practice, this study shows how healthcare professionals' engagement in narrative relations may contribute to upholding several foundational qualities which resonate with philosophies of person-centredness in everyday healthcare practice. RELEVANCE TO CLINICAL PRACTICE: Recognition of both the advantages and possible risks embedded in narrative relations in healthcare practice emphasises the obligation to collectively reflect on the repercussions of narrative relations in any local context. PATIENT OR PUBLIC CONTRIBUTION: Healthcare professionals contributed by sharing their experiential knowledge and reflections on narration in practice.</p>
Herzog, Philipp; Kube, Tobias; Rubel, Julian	2023	Why some psychotherapists benefit from feedback on treatment progress more than others: A belief updating perspective	Clinical Psychology: Science and Practice	30	4	468–479	<p>Monitoring of patient-reported outcomes and providing therapists with progress feedback has been shown to be beneficial for treatment outcomes (e.g., by preventing therapy failures). Despite recent advances in monitoring and feedback research, little is known about why some therapists benefit from feedback more than others. Addressing this issue, the present article uses the basic science literature on belief updating to propose a theoretical model for these between-therapist differences. In doing so, we provide a novel framework that allows testable hypotheses about when and how</p>

							feedback on therapy progress is likely to improve treatment outcomes. In particular, we argue that the integration of feedback and its effect on therapists' behavior depends on the weight therapists assign to their prior beliefs regarding treatment progress relative to the weight of the feedback received. We conclude by outlining some directions for future research on the underpinnings of this model, and point to some implications for the training of therapists and provision of feedback. Herzog, Thomas	2017	Humanistisch-existenzielle Perspektiven der Zwangsstrung. Existenzanalyse , Psychodrama und Personzentrierte Psychotherapie im Dialog	Existenzanalyse	34	1	54–61	Psychotherapeutische Konzepte verschiedener humanistisch-existenzieller Anstze werden miteinander in einen Dialog gebracht. Ausgehend vom konkreten Erscheinungsbild der Zwangserkrankung werden aus dem Blickwinkel der Existenzanalyse, des Psychodramas sowie der Personzentrierten Psychotherapie das jeweils spezifische Strungsverstndnis und therapeutische Vorgehen dargestellt und schlielich in einer Zusammenschau diskutiert. Ziel dabei ist es, die den drei Anstzen innewohnenden Gemeinsamkeiten und Unterschiedlichkeiten im Sinne der wechselseitigen Befruchtung sichtbar und damit einem weiterfhrenden Diskurs zugnglich zu machen.
Heshmati, Rasoul; Azmoodeh, Shahin; Caltabiano, Marie L.	2021	Pathway Linking Different Types of Childhood Trauma to Somatic Symptoms in a Subclinical Sample of Female College	The Journal of nervous and mental disease	209	7	497–504	Research has shown that women are more prone to childhood trauma and this state is associated with somatic symptoms. Also, people who have been exposed to traumatic experiences use experiential avoidance to reduce negative emotions. However, the mediating role of experiential avoidance in the relationship between childhood trauma and somatic symptoms is not clear, so, the present study investigated whether the relationships among different types of childhood trauma and somatic

		Students: The Mediating Role of Experiential Avoidance					<p>symptoms could be explained by experiential avoidance in female college students. In a cross-sectional study, 251 Iranian female college students with somatic symptoms were recruited from the University of Tabriz. Participants completed self-report scales, including the Persian version of Child Abuse Self-Reported Scale, Acceptance and Action Questionnaire-II (AAQ-II), and the Patient-health questionnaire (PHQ-15). A path analysis was used to empirically explore the relationships. Structural equation modeling analyses confirmed a partial mediation model. Study participants who had a higher level of emotional trauma reported higher levels of somatic symptoms. Emotional and neglect trauma showed significant positive relations with experiential avoidance. Bootstrapping results showed that experiential avoidance partially mediated the relationship between emotional trauma and somatic symptoms. Moreover, the association between neglect and somatic symptoms was fully mediated by experiential avoidance. These findings suggest that experiential avoidance might be one mechanism explaining how adverse emotional and neglect experiences influence somatic symptoms. Interventions addressing experiential avoidance through methods such as emotion-focused therapy and mindfulness are discussed as potential future directions for treating somatic symptoms in females who experienced emotional and neglect trauma.</p>
Heshmati, Rasoul; Wienicke, Frederik J.; Driessen, Ellen		The effects of intensive short-term dynamic psychotherapy on depressive symptoms,	Psychotherapy	60	4		<p>Intensive short-term dynamic psychotherapy (ISTDP) is theorized to reduce negative affect by challenging patients' defense mechanisms so that they can experience and work through attachment-trauma-related emotions. While ISTDP has been shown to decrease depressive symptoms in single treatment-resistant</p>

		negative affect, and emotional repression in single treatment-resistant depression: A randomized controlled trial					depression (TRD), it has not been established whether negative affect and emotional repression are reduced, as theorized. Next to depressive symptoms, this retrospectively registered (https://osf.io/v46gy) randomized controlled trial, therefore, examined the effects of ISTDP on emotional repression and negative affect in adults with TRD. Eighty-six adults with major depressive disorder, who had not responded to at least one trial of antidepressants were randomized to 20 sessions of ISTDP (N = 43) or a waitlist control condition (N = 43). Mixed-effect models on the intention-to-treat sample showed that compared to the control condition, ISTDP resulted in significantly lower posttreatment levels of depressive symptoms (d = -1.73), emotional repression (d = -1.91), and negative affect (d = -1.45). Similarly, ISTDP resulted in significantly lower levels of depressive symptoms (d = -2.67), emotional repression (d = -2.69), and negative affect (d = -1.85) at the 3-month follow-up. These results support the evidence base of ISTDP by showing that it can decrease depressive symptoms, emotional repression, and negative affect in TRD. Future studies should assess whether these effects are specific to ISTDP. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Hesser, Hugo	2022	Identifying causal mechanisms in psychotherapy: What can we learn from causal mediation analysis?	Clinical psychology & psychotherapy	29	3	1050–1058	Despite widespread interest in the development of process-based psychotherapies, little is still known about the underlying processes that underpin our most effective therapies. Statistical mediation analysis is a commonly used analytical method to evaluate how, or by which processes, a therapy causes change in an outcome. Causal mediation analysis (CMA) represents a new advancement in mediation analysis that employs causally defined direct and indirect effects based on

							<p>potential outcomes. These novel ideas and analytical techniques have been characterized as revolutionary in epidemiology and biostatistics, although they are not (yet) widely known among researchers in clinical psychology. In this paper, I outline the fundamental concepts underlying CMA, clarify the differences between the CMA approach and the traditional approach to mediation, and identify two important data analytical aspects that have been emphasized as a result of these recent advancements. To illustrate the key ideas, assumptions, and mathematical definitions intuitively, an applied clinical example from a previously published randomized controlled trial is used. CMA's main contributions are discussed, as well as some of the key challenges. Finally, it is argued that the most significant contribution of CMA is the formalization of mediation in a unified causal framework with clear assumptions.</p>
<p>Hesser, Hugo; Axelsson, Sandra; Bäcke, Victoria; Engstrand, Jonna; Gustafsson, Tina; Holmgren, Elin; Jeppsson, Ulrika; Pollack, Maria; Nordén, Kjell; Rosenqvist, Dan; Andersson, Gerhard</p>	2017	<p>Preventing intimate partner violence via the Internet: A randomized controlled trial of emotion-regulation and conflict-management training for individuals with aggression problems</p>	<p>Clinical psychology & psychotherapy</p>	24	5	1163–1177	<p>OBJECTIVE The aim of this randomized controlled trial was to investigate the effect of an Internet-delivered cognitive behaviour therapy (iCBT), which incorporated emotion-regulation and conflict-resolution techniques, on intimate partner violence (IPV). Another aim was to test the theoretical underpinnings of the treatment model using mediation analysis.</p> <p>METHOD Sixty-five participants with aggression problems in intimate adult relationships were recruited from the community and were randomly assigned to iCBT or to a monitored waitlist control. Participants were assessed with standardized self-report measures of IPV or aggression (Multidimensional Measure of Emotional Abuse, Revised Conflict Tactics Scale, and Aggression</p>

						<p>Questionnaire), relationship quality (Dyadic Adjustment Scale), anxiety or depression symptomatology (Patient Health Questionnaire; Generalized Anxiety Disorder Screener), at pretreatment, posttreatment (8 weeks), and 1-year follow-up. Process variables (subscales of Dysfunctional and Emotional Regulation Scale and Anger Rumination Scale) were assessed weekly over the active treatment phase.</p> <p>RESULTS</p> <p>Robust linear regression analysis of all randomized participants showed significant treatment effects on emotional abuse relative to control at postassessment. Mediation analysis using growth curve modeling revealed that the treatment effect was partially mediated by changes in emotion-regulation ability. Controlled effects on secondary outcomes were also observed. Analyses of uncontrolled effects indicted that gains on IPV were maintained at 1-year follow-up.</p> <p>CONCLUSIONS</p> <p>iCBT focusing on enhancing conflict-resolution skills and emotion-regulation ability has the potential to reduce IPV among self-recruited individuals with mild forms of abusive behaviour in intimate relationships. Emotion-regulation ability is potentially a key therapeutic process of change.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>Internet-delivered clinician-guided cognitive behaviour therapy is a viable treatment option for reducing intimate partner violence among self-recruited individuals with mild forms of abusive behaviour. For persons who display patterns of frequent and severe violence, other treatments are most likely needed. Emotion-regulation</p>

							training is potentially a key therapeutic component that ought to be incorporated in interventions targeting IPV.
Hessinger, Jonathan D.; Etingen, Bella; Larsen, Sadie E.; Hunley, Holly A.; Goldstein, Daniel A.; Day, Anne M.; Mayberry, Megan; Weber, Dana J.; Dolgin, Ron; Beyer, Jonathan A.; Maieritsch, Kelly P.	2023	Improving engagement and retention to treatment within VHA PTSD specialty care: Evolution of an outpatient program design	Psychological Services		19-148X(15-1559(Print)	241-247	The Veteran's Health Administration (VA) and Department of Defense (DoD) posttraumatic stress disorder (PTSD) clinical practice guidelines (2017) recommend individual, trauma-focused therapy as the gold standard of treatment for PTSD (i.e., evidence-based practices [EBP]). Moreover, these guidelines encourage the use of individual shared decision-making (SDM) to increase engagement and completion of EBPs for PTSD in line with current literature. This study retrospectively evaluated three models of program design of a VA PTSD specialty clinic over the past 8 years. In line with previous literature, the study hypothesized that leveraging individualized SDM in the clinic design would lead to increased completion of EBPs for PTSD. Analyses indicated an impact as the models shifted from a group-based model to an individualized model. Specifically, as compared to veterans who completed a group-based design, a greater proportion of those enrolled in the clinic were more likely to complete an EBP. These results may suggest that individualized, patient-centered treatment planning may be related to patient engagement in EBPs for PTSD in contrast with group-based models. Other programmatic changes, such as changes in treatment options presented to patients, a movement to focus on EBPs for PTSD, and expanded clinic hours and telehealth options, possibly impacted veteran engagement and completion in EBPs. The study highlights the potential impacts of a changing patient population within the clinic over a relatively short period. The observations are discussed, and limitations are highlighted. The study shares the hope for additional randomized prospective studies of program

							designs. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Hesterlee, Sharon; Amur, Shashi; Bain, Lisa J.; Carulli, John; Clarke, Sarah; Day, John W.; Gagnon, Cynthia; Hagerman, Katharine; Heatwole, Chad; Johnson, Nicholas E.; Moxley, Richard 3rd; Patel, Nikunj; Thornton, Charles; Kessel, Woodie; White, Molly	2017	Patient-Centered Therapy Development for Myotonic Dystrophy: Report of the Myotonic Dystrophy Foundation-Sponsored Workshop	Therapeutic innovation & regulatory science	51	4	516–522	Myotonic dystrophy (DM) is an autosomal dominant, repeat expansion, progressive disorder with no drug therapies. Consequently, to better define a regulatory pathway in anticipation of new treatment strategies under investigation, the Myotonic Dystrophy Foundation convened a workshop entitled "Patient-Centered Therapy Development for Myotonic Dystrophy" in September 2015. Participants included representatives from academia, industry, the patient community, the National Institutes of Health (NIH) and the Food and Drug Administration (FDA). Presenters described the symptom burden of the disease, and existing data on DM biomarkers, endpoints, natural history, and benefit-risk considerations. FDA participants helped clarify the regulatory requirements for new drug treatment approvals and DM-specific issues such as variability, slow progression, and low prevalence. Workshop attendees gained a better understanding of DM and the current status of existing data and tools to support therapeutic drug research and development.
Hetrick, Sarah E.; Cox, Georgina R.; Witt, Katrina G.; Bir, Juliet J.; Merry, Sally N.	2016	Cognitive behavioural therapy (CBT), third-wave CBT and interpersonal therapy (IPT) based interventions for preventing depression in	The Cochrane database of systematic reviews	2016	8	CD003380	BACKGROUND Depression is common in young people. It has a marked negative impact and is associated with self-harm and suicide. Preventing its onset would be an important advance in public health. This is an update of a Cochrane review that was last updated in 2011. OBJECTIVES To determine whether evidence-based psychological interventions (including cognitive behavioural therapy (CBT), interpersonal therapy (IPT) and third wave CBT)) are effective in preventing the onset of depressive disorder in

		<p>children and adolescents</p>				<p>children and adolescents.</p> <p>SEARCH METHODS We searched the specialised register of the Cochrane Common Mental Disorders Group (CCMDCTR to 11 September 2015), which includes relevant randomised controlled trials from the following bibliographic databases: The Cochrane Library (all years), EMBASE (1974 to date), MEDLINE (1950 to date) and PsycINFO (1967 to date). We searched conference abstracts and reference lists of included trials and reviews, and contacted experts in the field.</p> <p>SELECTION CRITERIA We included randomised controlled trials of an evidence-based psychological prevention programme compared with any comparison control for young people aged 5 to 19 years, who did not currently meet diagnostic criteria for depression.</p> <p>DATA COLLECTION AND ANALYSIS Two authors independently assessed trials for inclusion and rated their risk of bias. We adjusted sample sizes to take account of cluster designs and multiple comparisons. We contacted trial authors for additional information where needed. We assessed the quality of evidence for the primary outcomes using GRADE.</p> <p>MAIN RESULTS We included 83 trials in this review. The majority of trials (67) were carried out in school settings with eight in colleges or universities, four in clinical settings, three in the community and four in mixed settings. Twenty-nine trials were carried out in unselected populations and 53 in targeted populations. For the primary outcome of depression diagnosis at medium-term follow-up (up to 12 months), there were 32 trials with 5965 participants and</p>
--	--	---------------------------------	--	--	--	--

						<p>the risk of having a diagnosis of depression was reduced for participants receiving an intervention compared to those receiving no intervention (risk difference (RD) -0.03, 95% confidence interval (CI) -0.05 to -0.01; P value = 0.01). We rated this evidence as moderate quality according to the GRADE criteria. There were 70 trials (73 trial arms) with 13,829 participants that contributed to the analysis for the primary outcome of depression symptoms (self-rated) at the post-intervention time point, with results showing a small but statistically significant effect (standardised mean difference (SMD) -0.21, 95% CI -0.27 to -0.15; P value < 0.0001). This effect persisted to the short-term assessment point (up to three months) (SMD -0.31, 95% CI -0.45 to -0.17; P value < 0.0001; 16 studies; 1558 participants) and medium-term (4 to 12 months) assessment point (SMD -0.12, 95% CI -0.18 to -0.05; P value = 0.0002; 53 studies; 11,913 participants); however, the effect was no longer evident at the long-term follow-up. We rated this evidence as low to moderate quality according to the GRADE criteria. The evidence from this review is unclear with regard to whether the type of population modified the overall effects; there was statistically significant moderation of the overall effect for depression symptoms (P value = 0.0002), but not for depressive disorder (P value = 0.08). For trials implemented in universal populations there was no effect for depression diagnosis (RD -0.01, 95% CI -0.03 to 0.01) and a small effect for depression symptoms (SMD -0.11, 95% CI -0.17 to -0.05). For trials implemented in targeted populations there was a statistically significantly beneficial effect of intervention (depression diagnosis RD -0.04, 95% CI -0.07 to -0.01; depression symptoms SMD -0.32, 95% CI -0.42 to -0.23). Of note were the lack of</p>
--	--	--	--	--	--	---

						<p>attention placebo-controlled trials in targeted populations (none for depression diagnosis and four for depression symptoms). Among trials implemented in universal populations a number used an attention placebo comparison in which the intervention consistently showed no effect.</p> <p>AUTHORS' CONCLUSIONS</p> <p>Overall the results show small positive benefits of depression prevention, for both the primary outcomes of self-rated depressive symptoms post-intervention and depression diagnosis up to 12 months (but not beyond). Estimates of numbers needed to treat to benefit (NNTB = 11) compare well with other public health interventions. However, the evidence was of moderate to low quality using the GRADE framework and the results were heterogeneous. Prevention programmes delivered to universal populations showed a sobering lack of effect when compared with an attention placebo control. Interventions delivered to targeted populations, particularly those selected on the basis of depression symptoms, had larger effect sizes, but these seldom used an attention placebo comparison and there are practical difficulties inherent in the implementation of targeted programmes. We conclude that there is still not enough evidence to support the implementation of depression prevention programmes. Future research should focus on current gaps in our knowledge. Given the relative lack of evidence for universal interventions compared with attention placebo controls and the poor results from well-conducted effectiveness trials of universal interventions, in our opinion any future such trials should test a depression prevention programme in an indicated targeted population using a credible attention placebo</p>
--	--	--	--	--	--	---

							comparison group. Depressive disorder as the primary outcome should be measured over the longer term, as well as clinician-rated depression. Such a trial should consider scalability as well as the potential for the intervention to do harm.

Hewitt, Paul L.; Mikail, Samuel F.; Dang, Silvain S.; Kealy, David; Flett, Gordon L.	2020	Dynamic-relational treatment of perfectionism: An illustrative case study	Journal of clinical psychology	76	11	2028-2040	<p>OBJECTIVE Perfectionism has been described as a multidimensional core vulnerability factor in various forms of dysfunction and disorders. Recently, we described our empirically supported-dynamic-relational treatment for perfectionism. This treatment integrates psychodynamic and interpersonal principles to reduce perfectionism and symptoms and enhance relationships with others and self by focusing on underlying relational patterns.</p> <p>METHOD We discuss this approach and present Azure, a 27-year-old woman who completed our group treatment and subsequent individual therapy as a follow-up.</p> <p>RESULTS Azure underwent a comprehensive psychological pretreatment assessment, the results of which were used to develop a working formulation that guided the group and individual psychotherapy. A description of the</p>

							<p>formulation and her experience in therapy are discussed and pre- and post-treatment data illustrate changes in Azure's perfectionism and symptoms.</p> <p>CONCLUSIONS</p> <p>We discuss changes that occurred over the course of treatment.</p>
Hewitt, Paul L.; Qiu, Tianyou; Flynn, Carol A.; Flett, Gordon L.; Wiebe, Stephanie A.; Tasca, Giorgio A.; Mikail, Samuel F.	2020	Dynamic-relational group treatment for perfectionism: Informant ratings of patient change	Psychotherapy	57	2	197–205	<p>Although now there is accumulating research on the effectiveness of psychotherapy for perfectionism, this research has been based almost exclusively on self-report data. In this article, we describe analyses from the University of British Columbia Perfectionism Treatment Study assessing close other informant ratings of change in perfectionism traits and perfectionistic self-presentation. A total of 61 close other informants of patients who participated in a 10-week dynamic-relational treatment for perfectionism completed measures of patient trait and self-presentational facets of perfectionism at pretreatment, at posttreatment, and at a 4-month follow-up. In support of the effectiveness of the treatment, we found that close other measures of patients' self-oriented perfectionism, other-oriented perfectionism, and all three facets of perfectionistic self-presentation were significantly reduced at posttreatment and follow-up. Close other measures of patients' socially prescribed perfectionism did not show change over the course of treatment and follow-up. The findings are discussed in terms of the effectiveness of the dynamic-relational treatment of perfectionism and the utility of extending research by including close other measures of change in treatment-outcome research. Hibbs, Rebecca; Pugh, Mathew; Fox, John R. E.	2021	Applying emotion-focused therapy to work with the "anorexic voice" within anorexia nervosa: A brief intervention	Journal of Psychotherapy Integration		15 73- 36 96(Ele ctr oni c), 10 53- 04 79(Pri nt)	327-347	Existent treatments for anorexia nervosa (AN) have produced dissatisfactory outcomes. Research suggests that many people with AN experience an internal "voice" that is related to eating disorder symptoms and relapse. This study was designed to consider the feasibility and acceptability of a new emotion-focused therapy (EFT) of AN, which is designed to work directly with the anorexic voice (AV; EFT-AV). Six adult clients diagnosed with AN who were experiencing an AV and awaiting psychological treatment were recruited from an adult outpatient service. Informed by EFT and previous AV research, the intervention involved six weekly individual sessions that focused on transforming AV experiences and promoting self-compassion. Participants completed standardized measures of eating disorder symptoms, relating to the AV, illness beliefs, motivation to change, and hope of recovery. Participants were also interviewed at the conclusion of the intervention to ascertain their views of on its acceptability. Findings suggested good recruitment, retention, and treatment adherence, which supported the feasibility of the EFT-AV intervention. Thematic analysis of participant interviews indicated the intervention was acceptable and tolerable. Future directions for the treatment of AN, including the potential value of EFT-AV

							as an adjunct to existing therapies, are discussed. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Hidding, Christian	2016	Mediation und Gewaltfreie Kommunikation: Aus Konflikten Begegnungen schaffen	Gesprächspsychotherapie und Personzentrierte Beratung	47	2	79–83	Elemente der Gewaltfreien Kommunikation (GFK) im Rahmen von Mediation werden beleuchtet. Nach einem Einblick in Geschichte und Wesen der Mediation werden ihre Phasen errtert und Grnde fr ihren Einsatz reflektiert. Anschließend werden Grundlagen der GFK und ihrer Anwendung in der Mediation erlutert. Vor diesem Hintergrund werden Parallelen zwischen dem personzentrierten Ansatz und der GFK verdeutlicht und hinsichtlich ihrer Bedeutung fr die Mediation diskutiert.
Hides, Leanne; Quinn, Catherine; Stoyanov, Stoyan; Kavanagh, David; Baker, Amanda	2019	Psychological interventions for co-occurring depression and substance use disorders	The Cochrane database of systematic reviews	2019	11		<p>BACKGROUND Comorbid depression and substance use disorders are common and have poorer outcomes than either disorder alone. While effective psychological treatments for depression or substance use disorders are available, relatively few randomised controlled trials (RCTs) have examined the efficacy of these treatments in people with these comorbid disorders.</p> <p>OBJECTIVES To assess the efficacy of psychological interventions delivered alone or in combination with pharmacotherapy for people diagnosed with comorbid depression and substance use disorders.</p> <p>SEARCH METHODS We searched the following databases up to February 2019: Cochrane Central Register of Controlled Trials, PubMed, Embase, CINAHL, Google Scholar and clinical trials registers. All systematic reviews identified, were handsearched for relevant articles.</p> <p>SELECTION CRITERIA The review includes data from RCTs of psychological</p>

						<p>treatments for people diagnosed with comorbid depression and substance use disorders, using structured clinical interviews. Studies were included if some of the sample were experiencing another mental health disorder (e.g. anxiety); however, studies which required a third disorder as part of their inclusion criteria were not included. Studies were included if psychological interventions (with or without pharmacotherapy) were compared with no treatment, delayed treatment, treatment as usual or other psychological treatments.</p> <p>DATA COLLECTION AND ANALYSIS</p> <p>We used standard methodological procedures expected by Cochrane.</p> <p>MAIN RESULTS</p> <p>Seven RCTs of psychological treatments with a total of 608 participants met inclusion criteria. All studies were published in the USA and predominately consisted of Caucasian samples. All studies compared different types of psychological treatments. Two studies compared Integrated Cognitive Behavioural Therapy (ICBT) with Twelve Step Facilitation (TSF), another two studies compared Interpersonal Psychotherapy for Depression (IPT-D) with other treatment (Brief Supportive Therapy (BST) or Psychoeducation). The other three studies compared different types or combinations of psychological treatments. No studies compared psychological interventions with no treatment or treatment as usual control conditions. The studies included a diverse range of participants (e.g. veterans, prisoners, community adults and adolescents). All studies were at high risk of performance bias, other main sources were selection, outcome detection and attrition bias. Due to heterogeneity between studies only two</p>
--	--	--	--	--	--	--

						<p>meta-analyses were conducted. The first meta-analysis focused on two studies (296 participants) comparing ICBT to TSF. Very low-quality evidence revealed that while the TSF group had lower depression scores than the ICBT group at post-treatment (mean difference (MD) 4.05, 95% confidence interval (CI) 1.43 to 6.66; 212 participants), there was no difference between groups in depression symptoms (MD 1.53, 95% CI -1.73 to 4.79; 181 participants) at six- to 12-month follow-up. At post-treatment there was no difference between groups in proportion of days abstinent (MD -2.84, 95% CI -8.04 to 2.35; 220 participants), however, the ICBT group had a greater proportion of days abstinent than the TSF group at the six- to 12-month follow-up (MD 10.76, 95% CI 3.10 to 18.42; 189 participants). There were no differences between the groups in treatment attendance (MD -1.27, 95% CI -6.10 to 3.56; 270 participants) or treatment retention (RR 0.95, 95% CI 0.72 to 1.25; 296 participants). The second meta-analysis was conducted with two studies (64 participants) comparing IPT-D with other treatment (Brief Supportive Psychotherapy/Psychoeducation). Very low-quality evidence indicated IPT-D resulted in significantly lower depressive symptoms at post-treatment (MD -0.54, 95% CI -1.04 to -0.04; 64 participants), but this effect was not maintained at three-month follow-up (MD 3.80, 95% CI -3.83 to 11.43) in the one study reporting follow-up outcomes (38 participants; IPT-D versus Psychoeducation). Substance use was examined separately in each study, due to heterogeneity in outcomes. Both studies found very low-quality evidence of no significant differences in substance use outcomes at post-treatment (percentage of days abstinent, IPD</p>
--	--	--	--	--	--	--

							<p>versus Brief Supportive Psychotherapy; MD -2.70, 95% CI -28.74 to 23.34; 26 participants) or at three-month follow-up (relative risk of relapse, IPT-D versus Psychoeducation; RR 0.67, 95% CI 0.30 to 1.50; 38 participants). There was also very low-quality evidence for no significant differences between groups in treatment retention (RR 1.00, 95% CI 0.81 to 1.23; 64 participants). No adverse events were reported in any study.</p> <p>AUTHORS' CONCLUSIONS</p> <p>The conclusions of this review are limited due to the low number and very poor quality of included studies. No conclusions can be made about the efficacy of psychological interventions (delivered alone or in combination with pharmacotherapy) for the treatment of comorbid depression and substance use disorders, as they are yet to be compared with no treatment or treatment as usual in this population. In terms of differences between psychotherapies, although some significant effects were found, the effects were too inconsistent and small, and the evidence of too poor quality, to be of relevance to practice.</p>
Hiebler-Ragger, M.; Perchtold-Stefan, C. M.; Unterrainer, H. F.; Fuchshuber, J.; Koschutnig, K.; Nausner, L.; Kapfhammer, H. P.; Papousek, I.; Weiss, E. M.; Fink, A.	2021	Lower cognitive reappraisal capacity is related to impairments in attachment and personality structure in poly-drug use: an fMRI study	Brain imaging and behavior	15	4	2187–2198	<p>Insecure attachment, impaired personality structure and impaired emotion regulation figure prominently in substance use disorders. While negative emotions can trigger drug-use and relapse, cognitive reappraisal may reduce emotional strain by promoting changes in perspective. In the present study, we explored behavioral and neural correlates of cognitive reappraisal in poly-drug use disorder by testing individuals' capability to generate cognitive reappraisals for aversive events (Reappraisal Inventiveness Test). 18 inpatients with poly-drug use disorder and 16 controls completed the Adult Attachment Scale, the Emotion Regulation Questionnaire, the Brief</p>

							<p>Symptom Inventory, the Wonderlic Personnel Test, and the Operationalized Psychodynamic Diagnosis Structure Questionnaire, as well as two versions of the Reappraisal Inventiveness Test (during fMRI and outside the lab). Compared to controls, polydrug inpatients reported impaired personality structure, attachment and emotion regulation abilities. In the Reappraisal Inventiveness Test, poly-drug inpatients were less flexible and fluent in generating reappraisals for anger-eliciting situations. Corresponding to previous brain imaging evidence, cognitive reappraisal efforts of both groups were reflected in activation of left frontal regions, particularly left superior and middle frontal gyri and left supplemental motor areas. However, no group differences in neural activation patterns emerged. This suggests that despite cognitive reappraisal impairments on a behavioral level, neural reflections of these deficits in poly-drug use disorder might be more complex.</p>
Hildebrandt, Ursula C.; Graham, J. Christopher; Grant, Therese M.	2020	Predictors and moderators of improved social-emotional functioning in mothers with substance use disorders and their young children enrolled in a relationship-based case	Infant mental health journal	41	5	677–696	<p>Mothers with substance use disorders (SUDs) typically have trauma histories and psychosocial difficulties that lead to poor social-emotional functioning and disrupted mother-child relationships. This 12-month study explored associations of family adverse circumstances and services (case management, therapeutic, and community-based) received by 57-mothers with SUDs and their infants (less than 24-months-old) with changes in social-emotional functioning. All mothers were enrolled in a relationship-based case management program (Parent-Child Assistance Program [PCAP]) that emphasized connecting mothers to appropriate community services. A subset of mothers was additionally provided a trauma-focused psychotherapeutic intervention (infant-parent</p>

		management program				<p>psychotherapy [IPP]). Dyads in both treatment groups improved in overall social-emotional functioning as assessed by the Functional Emotional Assessment Scale (FEAS). A combined-sample regression analysis revealed that improved FEAS scores were significantly predicted by the number of community services received but not by PCAP case management hours (IPP was not included in this analysis). More adverse circumstances were associated with less improvement in social-emotional functioning in the children; but among the mothers trauma level did not predict FEAS scores. We also found a moderating effect of trauma: Dyads with relatively more adversity showed a significantly greater association of community services received with improvement in FEAS scores than did those with relatively less adversity.</p> <p>Las madres con trastornos por abuso de sustancias (SUDs) típicamente tienen historias de trauma y dificultades sicosociales que conducen al débil funcionamiento socio-emocional y relaciones madre-niño trastornadas. Este estudio de 12 meses exploró asociaciones entre circunstancias adversas de familia y servicios (de dirección de caso, terapéuticos, basados en la comunidad) que recibieron 57 madres con SUDs y sus infantes (menos de 24 meses de edad) con cambios en el funcionamiento socio-emocional. Todas las madres fueron inscritas en un programa de dirección de caso con base en la relación (Programa de Asistencia al Progenitor y Niño - PCAP) que enfatizaba la conexión de las madres con adecuados servicios comunitarios. Un subgrupo de madres recibió además una intervención sicoterapéutica con enfoque en el trauma (Sicoterapia de Infante-Progenitor - IPP). Las díadas en ambos grupos de tratamiento mejoraron en el funcionamiento socio-</p>
--	--	--------------------	--	--	--	--

						<p>emocional en términos generales tal como se les evaluó por medio de la Escala Funcional de Evaluación Emocional (FEAS). Un análisis de regresión que combinó los grupos muestras reveló que los mejorados puntajes en FEAS habían sido pronosticados significativamente por el número de servicios comunitarios recibidos, pero no por las horas del programa de dirección de caso PCAP (no se incluyó la IPP en este análisis). Se asociaron las circunstancias más adversas con un menor mejoramiento en el funcionamiento socio-emocional en los niños; pero entre las madres, el nivel del trauma no predijo los puntajes FEAS. También encontramos un efecto moderador del trauma: las díadas con más adversidad relativamente mostraron significativamente mayor asociación de servicios comunitarios recibidos con mejoras en los puntajes FEAS que aquellas con menor adversidad relativamente. Palabras claves: Salud mental infantil, trastornos maternos por abuso de sustancias, trauma, servicios comunitarios, Sicoterapia de Infante-Progenitor.</p> <p>Les mères ayant des troubles liés à la toxicomanie (TLT) ont typiquement des passés de trauma et des difficultés psychosociales qui mènent à un mauvais fonctionnement socio-émotionnel et à des relations mère-enfant perturbées. Cette étude de 12 mois a exploré les liens de circonstances familiales adverses et les services (gestion des cas, services thérapeutiques, et services au niveau de la communauté) reçus par 57 mères ayant des TLT et leurs bébés (moins de 24 mois) avec des changements dans le fonctionnement socio-émotionnel. Toutes les mères ont été inscrites dans un programme de gestion de cas basé sur la relation (Programme d'Assistance Parent-Enfant) mettant l'accent</p>
--	--	--	--	--	--	--

						<p>sur la référence des mères aux services communautaires appropriés. Un sous-groupe de mères a en plus reçu une intervention psychothérapeutique centrée sur le trauma (Psychothérapie Bébé-Parent). Les dyades des deux groupes de traitement se sont améliorées dans le fonctionnement socio-émotionnel général, évalué par l'Echelle d'Evaluation Emotionnelle Fonctionnelle (Functional Emotional Assessment Scale, soit FEAS). Une analyse de régression d'échantillons combinés a révélé que les scores FEAS améliorés étaient fortement prédits par le nombre de services communautaires reçus mais pas par les heures de gestion de cas FCAP (l'IPP n'a pas été incluse dans cette analyse). Plus de circonstances adverses était lié à moins d'amélioration dans le fonctionnement socio-émotionnel chez les enfants. Mais chez les mères le niveau de trauma ne prédisait pas les scores FEAS. Nous avons aussi découvert un effet modérateur du trauma: les dyades avec relativement plus d'adversité faisaient preuve d'une association bien plus élevée avec les services communautaires reçus avec une amélioration dans les scores FEAS que les dyades avec relativement moins d'adversité. Mots clés: Santé Mentale du Nourrisson, Troubles Liés à la Toxicomanie Maternelle, Trauma, Service Communautaires, Psychothérapie Bébé-Parent.</p> <p>Prädiktoren und Moderatoren einer verbesserten sozial-emotionalen Funktionsfähigkeit bei Müttern mit Substanzstörungen und ihren kleinen Kindern im Kontext eines beziehungsbasierten Fallmanagementprogramms Bei Müttern mit Substanzstörungen (substance use disorders; SUDs) gibt es oft traumatische Erlebnisse in der Vergangenheit und psychosoziale Schwierigkeiten, die zu einer schlechten sozial-emotionalen</p>

						<p>Funktionsfähigkeit und gestörten Mutter-Kind-Beziehungen führen können. Diese 12 Monate lange Studie untersuchte Assoziationen zwischen widrigen familiären Umständen und Leistungen (Fallmanagement, therapeutisch Leistungen und gemeindebasierte Leistungen), die 57 Mütter mit SUDs und ihre Säuglinge (unter 24 Monaten) mit veränderter sozial-emotionaler Funktionsfähigkeit erhalten haben. Alle Mütter nahmen an einem beziehungsbasierten Fallmanagementprogramm (Parent-Child Assistance Program; PCAP) teil, bei dem der Schwerpunkt auf der Vermittlung der Mütter an geeignete gemeindebasierte Leistungen lag. Ein Teil der Mütter erhielt zusätzlich eine traumafokussierte psychotherapeutische Intervention (Infant-Parent Psychotherapy; IPP). In beiden Behandlungsgruppen verbesserte sich die sozial-emotionale Gesamtfunktionsfähigkeit, was anhand der Functional Emotional Assessment Scale (FEAS) festgestellt werden konnte. Eine Regressionsanalyse ergab, dass verbesserte FEAS-Scores signifikant durch die Anzahl der erhaltenen gemeindebasierten Leistungen, jedoch nicht durch die PCAP-Fallmanagementstunden vorhergesagt wurden (IPP wurde in dieser Analyse nicht berücksichtigt). Ein größeres Ausmaß an widrigen Umständen war mit einer geringeren Verbesserung der sozial-emotionalen Funktionsfähigkeit bei den Kindern assoziiert. Bei den Müttern konnten die FEAS-Werte jedoch nicht von den traumabezogenen Daten vorhergesagt werden. Außerdem wurde einen moderierenden Effekt von Trauma gefunden: Mutter-Kind Dyaden mit verhältnismäßig widrigeren Umständen zeigten eine signifikant größere Assoziation zwischen erhaltenen gemeindebasierten Leistungen und</p>

Hill, Clara E.; Knox, Sarah; Duan, Changming	2023	Psychotherapist advice, suggestions, recommendations: A research review	Psychotherapy	60	3	295-305	<p>Psychotherapists provide at least some advice, suggestions, and recommendations (ASR) in most treatment approaches. We define ASR, offer clinical examples, and review the research evidence for the immediate in-session, immediate delayed, and intermediate effects of ASR, as well as for the moderators of these effects in individual psychotherapy. In seven studies with 327 clients and 131 therapists, we found evidence of neutral immediate in-session outcomes (e.g., client experiencing levels), neutral immediate delayed outcomes (e.g., client-rated helpfulness during postsession videotape reviews), and positive intermediate outcomes (e.g., implementation of recommendations as rated in subsequent sessions) for ASR. These differences may be related to methodological variations in studies in addition to the different timing of the outcome measurement. In terms of moderators, there is some evidence that the working alliance, client collaboration prior to the ASR, content of the ASR, and therapist and client attachment styles moderate the effects of immediate in-session outcomes, and that type, difficulty, and therapist influence moderate the effects of</p>

							intermediate outcomes of ASR. We conclude with research limitations, training implications, and therapeutic practices related to ASR. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Hill, Clara E.; Norcross, John C.	2023	Skills and methods that work in psychotherapy: Observations and conclusions from the special issue	Psychotherapy	60	3	407-416	We draw recommendations and conclusions from the articles presented in this special issue and the companion special section in Psychotherapy Research on evidence-based therapist skills and methods. For distal (end-of-treatment) outcome, 10 skills/methods were judged to be demonstrably effective (affirmation/validation, paradoxical interventions, homework, routine outcome monitoring, strength-based methods, emotional regulation, imagery rehearsal therapy and exposure relaxation and rescripting therapy for nightmares, meditation/mindfulness/acceptance, behavioral activation, cognitive restructuring) and four were probably effective (rupture repair, role induction, collaborative assessment methods, chairwork). For intermediate (postsession or midtreatment) outcome, one method was judged to be demonstrably effective (cognitive-experiential dreamwork) and two methods probably effective (paradoxical interventions, homework). For immediate (in-session) outcomes, five skills/methods were judged to be probably effective (in-dialog silences, extended silences, role induction, strength-based methods, and emotion regulation). For the rest of the immediate, intermediate, or distal outcomes for skills/methods, there was either no or insufficient research available upon which to base judgments. Possible harmful effects, diversity considerations, and research limitations are summarized. The article ends with training implications, therapeutic practices, and the formal conclusions of the interorganizational Task Force

							on Psychotherapy Skills and Methods that Work. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Hill, N.; Geoghegan, M.; Shawe-Taylor, M.	2016	Evaluating the outcomes of the STEPPS programme in a UK community-based population; implications for the multidisciplinary treatment of borderline personality disorder	J. Psychiatr. Ment. Health Nurs. (Journal of psychiatric and mental health nursing)	23	6-7	347-356	<p>Accessible summary What is known on the subject? Individuals with a diagnosis of Borderline Personality Disorder (BPD) now constitute a substantial portion of the caseload for community teams. Specialized treatments for BPD often consume a large portion of available psychology resources and also involve lengthy waiting lists. The STEPPS programme is a treatment approach which is growing in evidence, particularly in the US. However, further evidence for the effectiveness of this programme within the UK healthcare system is needed.</p> <p>What this study adds to existing knowledge The results of this study support the preliminary evidence for the effectiveness of STEPPS in a UK community-based population. A reduction in symptom severity was in evidence. Novel measures were used to build on previous evaluations of the STEPPS programme. These measures show a significant reduction in patients' affinity for unhelpful schemas, as well as an increase in patients' self-reported quality of life; an important perspective for a recovery focused approach to treatment. What are the implications for practice? The STEPPS programme has shown its merit as an effective and more accessible treatment option for the community-based treatment of BPD, though some methodological limitations are noted. Furthermore, the results of this study demonstrate that STEPPS can be delivered effectively by teams of facilitators from different professional backgrounds who do not necessarily have extensive training in psychotherapeutic interventions. The result is a well-rounded and diverse skill set possessed by the team of facilitators, adding to the richness of the patient's</p>

							<p>recovery journey and leading to a more favourable spread of teams? resources. Abstract Aims & Background Systems Training for Emotional Predictability and Problem Solving (STEPPS) is a group treatment for individuals with a diagnosis of Borderline Personality Disorder (BPD) which has a growing evidence base, particularly in the US. Evidence is sparse for its use with UK populations, and this study seeks to assess the reliability of this evidence, whilst adding to existing knowledge through the use of additional measures. Method Thirty patients completed one of four STEPPS groups. Data regarding symptom severity, quality of life and affinity for maladaptive schemas were collected at the start and end of the group to allow pairwise analysis. Results Significant reductions in symptom severity and affinity for maladaptive schemas were in evidence, as well as highly significant increases in patients' self-reported quality of life. Implications The results provide further evidence for the efficacy of STEPPS with a UK sample of patients with a diagnosis of BPD, though limitations with the design of this study warrant caution. They also show that the programme achieves this level of efficacy when delivered by facilitators who are not intensively trained in psychological treatment models. As such, the STEPPS programme provides a resourceful approach to the treatment of BPD in a UK community-based setting.</p>
Hiller, Regina; Hensel, Thomas	2019	ResonaT - Ressourcenorientierte narrative Traumatherapie. Kindern und Jugendlichen mit komplexen					<p>Mit der "Ressourcenorientierten narrativen Traumatherapie mit Kindern und Jugendlichen mit komplexen Traumafolgestörungen" (ResonaT) wird eine neue, klinisch erprobte Methode zur Psychotherapie von Kindern und Jugendlichen mit komplexen Traumafolgestörungen vorgestellt. ResonaT beruht auf der Traumaverarbeitung mit Hilfe von Tiergeschichten, und</p>

		Traumafolgestru- ngen helfen					<p>bezieht sich in ihrem Therapieverständnis auf das Wirkfaktorenmodell von K. Grawe und den neurobiologischen Selbstheilungsprozess der Gedächtnisrekonsolidierung. Existierende narrative Ansätze werden in kompakter Form präsentiert, die ResonaT-Methode wird theoretisch fundiert, und eine Sammlung von insgesamt 90 Beispielnarrativen für unterschiedliche Themen und Situationen wird vorgelegt. Diese Auswahl an vorformulierten Tiergeschichten ermöglicht es dem Therapeuten, ohne großen zusätzlichen Schreibaufwand mit dem Ansatz in der täglichen Praxis zu arbeiten. - Inhalt: (1) Ausgewählte narrative Ansätze in der modernen (Trauma-)Psychotherapie (Konstruktivismus; Emotionsfokussierte Therapie (EFT); Narrativ-konstruktive Traumatherapie; Schonende Traumatherapie; Imagery Rescripting & Reprocessing Therapy (IRRT); Szenisch-narrative Ansätze (Traumabezogene Spieltherapie; Pesso Boyden System Psychomotor - PBSP); Linguistische Analysen von Trauma-Narrativen; Ansätze von Narrativarbeit in der traumafokussierten Kinder- und Jugendlichenpsychotherapie). (2) ResonaT - Ressourcenorientierte narrative Traumatherapie bei Kindern und Jugendlichen mit komplexen Traumafolgestörungen. (3) Beispielgeschichten nach der ResonaT-Methode zu zentralen Themen komplexer Traumatisierung im Kindesalter. - - über die Homepage des Verlags werden unterschiedliche Tierbilder zum Download zur Verfügung gestellt, die die Grundemotionen Angst, Wut und Trauer ausdrücken. Dieser visuelle Input soll den Verarbeitungsprozess unterstützen und kann den Kindern beim Vorlesen der Narrative vorgelegt werden. - Das Buch wurde für die vorliegende zweite Auflage erweitert.</p>

<p>Hillman, Justin W.; Gerstenblith, Judith A.; Jankauskaite, Greta; Mohr, Jonathan J.; Hill, Clara E.</p>	<p>2023</p>	<p>Development and validation of the Barriers to Using Immediacy Scale (BUIS)</p>	<p>Journal of Counseling Psychology</p>	<p>70</p>	<p>5</p>	<p>571–583</p>	<p>Immediacy is a skill therapists use to process the therapeutic relationship in the here and now. Although immediacy has been shown to enhance the therapeutic process, therapists are often reluctant to use it (Hill et al., 2018). In three studies, we developed and tested a measure to assess reasons that therapists avoid using this skill: the Barriers to Using Immediacy Scale (BUIS). In Study 1, 185 North American therapist trainees completed the 45-item pilot measure. Exploratory factor analysis supported a four-factor structure (Concerns About Client Reactions, Concerns About Therapist Reactions, Negative Beliefs About Immediacy, Lack of Skills for Using Immediacy). In Study 2, with an international sample of 352 therapist trainees and professionals, confirmatory factor analyses supported the original four correlated factors model, as well as alternative models. In Study 3, 89 undergraduate students in a helping skills class completed the BUIS at three points during the semester. Students' total barriers and barriers due to a lack of skills decreased, but other perceived barriers did not decrease after training. Across all three studies, predicted correlations of BUIS scores were found with measures of self-efficacy for using immediacy, adherence to different theoretical orientations, communication style, and attachment style. Incremental validity was supported by the association of BUIS scores with measures of open communication and attachment style, after accounting for self-efficacy for immediacy. Limitations and future directions are discussed. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
<p>Hintermeier, Sonja</p>	<p>2016</p>	<p>Psychodrama-Psychotherapie</p>					<p>Symptomatik, Entwicklung und Behandlung von Persönlichkeitsstrungen werden aus psychodramatischer</p>

		bei Persnlichkeitsst rungen					<p>Sicht beleuchtet und ein Modell einer strungsspezifischen, strukturbezogenen Psychodramatherapie bei Persnlichkeitsstrungen wird vorgestellt. Psychodrama wird als erlebnisorientiertes, humanistisches Therapieverfahren erkennbar, welches das Wiedererlangen von (blockierter) Spontaneitt und Kreativitt zum Ziel hat. Anhand von Falldarstellungen wird deutlich gemacht, wie die Gestaltung der therapeutischen Beziehung und der flexible Einsatz der umfangreichen Methoden in der Psychodramatherapie eine Verbesserung der Symptomatik frdern knnen. - Inhalt: (1) Persnlichkeitsstrungen - was ist das? Hirsch, Oliver; Chavanon, Mira Lynn; Christiansen, Hanna	2019	Emotional dysregulation subgroups in patients with adult Attention-Deficit/Hyperactivity Disorder (ADHD): a	Scientific reports	9	1	5639	<p>Emotion regulation deficits (ERD) are evident in about 34-70% of the adults with ADHD. In contrast to this, they are not considered in the diagnostic criteria of the disorder. In a recent study of our research group using confirmatory factor analysis, we modeled positive and negative emotion as well as emotion regulation skills along with the classical ADHD-core symptoms. We showed that negative affect and the failure to apply adaptive emotion</p>

		cluster analytic approach					regulation skills were distinct and indicative dimensions in adult ADHD. In this study, we used a person-centered approach based on cluster analysis to subtype patients on the presence or relative absence of ERD. This results in important information to individualize treatment decisions. We found two clusters, with cluster 2 showing high ERD that were associated with higher impairments indicated by depressive mood, negative affect and elevated psychological distress. There were also higher rates of comorbidity in cluster 2 such as somatoform disorders which were associated with ERD. Women were overrepresented in this cluster 2. Neuropsychological variables did not contribute significantly to cluster formation. In conclusion, ADHD in adults is a heterogeneous disorder with specific subgroups that need differential treatment approaches.
Hirschberg, Rainer; Strecker, Viktoria-Katharina	2018	Contract Focused Group Therapy - Results of a Second Evaluation	Praxis der Kinderpsychologie und Kinderpsychiatrie	67	8	736-752	Contract Focused Group Therapy - Results of a Second Evaluation Contract focused group therapy (AFoG) can be understood as a successful transformation of systemic solution focused mindsets into a group therapy concept for children and adolescents. The current evaluation study intends to investigate the effectiveness of AFoG. The sample size includes 72 children who attended AFoG and their parents. A pre-post-design was used to measure the perceived exposure of the child's problem behavior via caregiver report (CBCL 4-18) and self-report (YSR 11-18) at the beginning and three months after group therapy. Based on t-tests, the hypothesis that children and parents report significantly lower symptoms after finishing AFoG than at the beginning of the group therapy can be confirmed. Especially children and adolescents who were assessed as highly displaying several behavioral problems (t-values between 71-80), show a

							clear decrease in the perceived symptom load in both the self-report and the caregiver report. Moreover, the clinical significance of the decrease were examined by using the Reliable Change Index. In this sense, a positive effect is recorded. Further research inclusive a control group is needed to support the effectiveness of AFoG.
Hirth, Ruth	2017	Psychoonkologische Belastungen bei gastrointestinalen Tumorpatienten					Gastrointestinale Tumorpatienten leiden bei ihrer Akutaufnahme im Krankenhaus und in der sich anschließenden Chemotherapie unter somatischen, psychischen und sozialen Belastungen, die sie psychoonkologisch behandlungsbedürftig erscheinen lassen. Bei 60 % dieser Patienten wurde ein solcher Behandlungsbedarf festgestellt. Das Anliegen der Arbeit war es, neben der Ermittlung des psychoonkologischen Betreuungsbedarfs, die Teilnahmebereitschaft dieser Patienten an einer psychoonkologischen Intervention festzustellen und zwei unterschiedliche Therapieverfahren (kognitiv-verhaltenstherapeutisch ausgerichtete Gesprächstherapie und Entspannungstherapie in Form einer progressiven Muskelrelaxation) mit einer Kontrollgruppe (Darreichung von Informationsmaterial über das Krankheitsbild) zu vergleichen. Es konnte ein positiver Effekt der Intervention, besonders der Gesprächstherapie, auf die Reduktion der Angst und Depression bei hoch belasteten Tumorpatienten nachgewiesen werden. Der Betreuungsbedarf derjenigen Patienten, die nur Informationsmaterial über die besagte Krankheit erhielten, veränderte sich dagegen in der Zeit ihrer Chemotherapie nicht. Verlaufsbahngig konnte gezeigt werden, dass die Veränderung des psychoonkologischen Betreuungsbedarfs bereits kurz nach der Intervention einsetzt. Es gab aber auch Patienten, die erst im Verlauf der Intervention

						<p>whrend der Chemotherapie einen psychoonkologischen Betreuungsbedarf entwickelten, den sie zu Beginn der Untersuchung nicht hatten. Auch diese Patienten konnten durch die psychotherapeutischen Interventionsmanahmen erfolgreich behandelt werden. Wider Erwarten verbesserte sich die Lebensqualitt der Patienten trotz Abnahme ihrer Angst- und Depressionswerte durch die psychoonkologische Betreuung nicht. Der psychoonkologische Betreuungsbedarf gastrointestinaler Patienten und seine Vernderung hngen von ihrem Geschlecht und ihrem Alter ab. Tumorpatientinnen haben einen hheren psychoonkologischen Betreuungsbedarf und verbessern sich in ihren psychischen Strungen schneller als mnliche Patienten. ltere Tumor-patienten (> 70 Jahre) haben einen hheren psychoonkologischen Betreuungsbedarf als jngere Patienten. Bei jngeren Tumorpatienten vermindern sich jedoch die somatischen, psychischen und sozialen Belastungen durch die Intervention. Der Krankheitsstatus (Erst- oder Zweiterkrankung, Rezidiv, Grad der Metastasierung), das Behandlungsziel (kurativ, palliativ), der Funktionszustand des Patienten (normale krperliche Aktivitt, Einschrnkung durch Bettruhe) und Begleiterkrankungen haben keinen entscheidenden Einfluss auf den psychoonkologischen Betreuungsbedarf der Patienten und auf seine Vernderung durch die Intervention. Der Einfluss von Copingstrategien auf die Verarbeitung des Krankheitserlebens wurde untersucht. Die Neubewertung emotional belastender Ereignisse im Sinne von Gross (2010) hat einen prognostisch positiven Einfluss auf die Vernderung des psychoonkologischen Betreuungsbedarfs und der Depressivitt der Tumorpatienten. Durch einen</p>
--	--	--	--	--	--	--

							<p>Copingstil in Form der Unterdrückung emotional belastender Ereignisse, konnten Veränderungen der Angst der Patienten durch die Intervention erzielt werden. Es konnte in der Untersuchung nicht gezeigt werden, dass bei der Verarbeitung emotional belastender Ereignisse während einer Therapiesitzung in der Entspannungsgruppe eine Pulsfrequenzreduktion eintritt. Neben den eingesetzten Interventionsverfahren (kognitiv ausgerichtete Gesprächstherapie und Entspannungstherapie) hängt der psychotherapeutische Interventionserfolg während der Chemotherapie der Patienten mit gastrointestinalen Tumoren stark von der deren Motiviertheit ab (im Hinblick auf Behandlungsmotiv und ihre aktive Mitarbeit) und sollte bereits vor Beginn der psychoonkologischen Intervention gefördert werden.</p>
Hochgerner, Markus	2022	Diagnostische Perspektiven in der humanistischen Psychotherapie					<p>Das vorrangig vom subjektiven Erleben und interaktioneller Dynamik in wechselseitiger Bezogenheit geprägte Menschenbild der humanistischen Psychotherapie steht als eine der vier Grundströmung der Psychotherapie einerseits in Abgrenzung zu defizit- bzw. konfliktorientierten Grundannahmen der behavioralen und psychodynamischen Verfahren und vertritt andererseits einen grundstzlich am menschlichen Entwicklungspotenzial ausgerichteten Zugang zum Erleben und Verhalten mit der Leitidee, die noch unvollständige oder leidvoll eingeschränkte Selbstentwicklung des Individuums zu unterstützen. Humanistische Diagnostik berücksichtigt wesentlich die diagnostische Expertise der leidenden Person im gemeinsamen dialogisch-therapeutischen Prozess, der weniger zuschreibend-festlegend, sondern vorrangig als gemeinsame hermeneutische Suchbewegung in einer diagnostisch gestützten, und begegnungsorientierten</p>

						Arbeitssituation verstanden wird. (c) Springer-Verlag GmbH Deutschland
Hochgerner, Markus; Schwarzmann, Melitta	2018	Psychosomatik in der Integrativen Gestalttherapie				Die Rolle der Psychosomatik in der Gestalttherapie wird dargestellt. Dabei werden zuerst die Grundannahmen einer psychosomatischen Sicht des Menschen und ein psychosomatisches Entwicklungs- und Strungsmodell dargelegt. Hierbei werden auch die Möglichkeiten und Grenzen psychosomatischer Strungs- und Behandlungskonzepte in der Integrativen Gestalttherapie aufgezeigt. Die zentralen Leidenszustände der Seinsangst und mangelnder Selbstgewissheit werden mit Hilfe der Ergebnisse einer qualitativen Untersuchung näher betrachtet. Dabei wird erlutert, wie diese Leidenszustände psychodiagnostisch und psychodynamisch zu erkennen sind, welche wirksamen Heilfaktoren sich identifizieren lassen, welche psychotherapeutische Kultur wichtig ist und welche psychotherapeutischen Konsequenzen diese Krankheitsbilder fordern, wobei die Phnomene der Regression und der Progression besonders beachtet und wesentliche psychotherapeutische Arbeitsebenen (Arbeit am Körper, kreative Medien, verbale Arbeit) benannt werden. Schlielich wird auf die psychotherapeutische Haltung in der Behandlung psychosomatisch Erkrankter eingegangen.
Hochstger, Nikolas; Svegjarto, Olivia	2018	Personenzentrierte Pdagogik als Pdagogik der Beziehung - theoretische und praktische berlegungen der Arbeitsgemeinschaft				In der "Arbeitsgemeinschaft fr Personenzentrierte Pdagogik" in Wien arbeitet derzeit eine Gruppe von Personenzentrierten Psychotherapeutinnen und Psychotherapeuten an der Applikation personenzentrierten Wissens in verschiedenen Bereichen der Pdagogik. Vor diesem Hintergrund erfolgt eine Aufarbeitung des personenzentrierten Verhltnisses zum Arbeitsfeld der Pdagogik. Die Bedeutung des Begriffes "Personenzentriertes Lernen" im heutigen Kontext wird

		"Personenzentrierte Pädagogik"					diskutiert, der Begriff des "Facilitators" wird erläutert, und Pädagogik und Therapeutik werden in Beziehung gesetzt. Des Weiteren wird das eigene Konzept formuliert, in dem speziell auf konstruktive Beziehungsgestaltungen innerhalb des pädagogischen Settings Bezug genommen wird. Dabei fokussieren wir die besondere Bedeutung der Beziehungsgestaltung der Pädagogin bzw. des Pädagogen und gehen im weiteren Weg von einer schlerzentrierten hin zu einer personenzentrierten Perspektive unter Einbezug einer resonanztheoretischen Perspektive.
Hodiamont, Farina; Hock, Helena; Ellis-Smith, Clare; Evans, Catherine; Wolf-Linder, Susanne de; Jünger, Saskia; Diehl-Schmid, Janine; Burner-Fritsch, Isabel; Bausewein, Claudia	2021	Culture in the spotlight-cultural adaptation and content validity of the integrated palliative care outcome scale for dementia: A cognitive interview study	Palliative medicine	35	5	962–971	BACKGROUND: Dementia is a life-limiting disease with high symptom burden. The Integrated Palliative Care Outcome Scale for Dementia (IPOS-Dem) is the first comprehensive person-centered measure to identify and measure palliative care needs of people with dementia. However, such a measure is missing in the German health care system. AIM: To develop a culturally adapted German version of the IPOS-Dem and determine its content validity as a foundation for comprehensive psychometric testing. DESIGN: Cognitive interview study with intermittent analysis and questionnaire adaptation. Interview guide and coding frame followed thematic analysis according to Willis complemented by Tourangeau's model of cognitive aspects of survey methodology: comprehension, retrieval, judgment, response. PARTICIPANTS: Purposive sample with professionals (n = 29) and family carers (n = 6) of people with advanced dementia in seven nursing homes and person's own home care in four interview rounds (n = 11; 10; 7; 7). RESULTS: IPOS-Dem was regarded as comprehensive and accessible. Cultural adaptation pertained to issues of comprehension and judgment. Comprehension challenges referred to the person-

						centered concept of "being affected by" used in the POS-measures. Judgment problems related to persons with limited communication causing challenges in assessment. CONCLUSION: Most issues of cultural adaptation could be addressed by questionnaire modifications. However, interviews unveiled fundamental challenges for using proxy reported person-centered assessments. Continuous training on how to use the instrument is imperative to integrate the person-centered approach of palliative care into nursing homes as a key provider of generalist palliative care for people with dementia. The refined version is ready for psychometric testing.
Hoehne, Katja; Vrtička, Pascal; Engert, Veronika; Singer, Tania	2022	Plasma oxytocin is modulated by mental training, but does not mediate its stress-buffering effect	Psychoneuroendocrinology	141		105734 Based on its role in social processing and stress, oxytocin has been suggested to mediate stress reduction of socio-affective, compassion-based mental training. We tested this hypothesis in the ReSource Project, a 9-month longitudinal mental training study. Participants practiced three different types of mental training, targeting either attentional abilities (Presence Module), socio-affective or socio-cognitive abilities (Affect and Perspective Modules). We investigated plasma oxytocin levels, and their link to cortisol and subjective reactivity to acute psychosocial stress as a function of previous mental training (n = 313). In a subsample (n = 113), to better understand oxytocin's involvement in the effects of socio-affective training, we explored oxytocin, cortisol and subjective experiential responses to a single Loving-kindness Meditation (LKM) conducted after three months of Affect training (versus rest without prior training). We found that, independent of mental training, stress triggered acute oxytocin release. Following a single LKM, however, acute oxytocin release was unaffected. Training

							<p>effects were only found in overall oxytocin release during both, stress and LKM. Compared to no training, 3-month compassion-based Affect training decreased overall oxytocin levels in the context of psychosocial stress, but increased overall oxytocin levels during LKM. Training-induced changes in overall oxytocin were unrelated to cortisol and subjective stress reactivity. Based on Quintana and Guastella's (2020) theory of oxytocin as an allostatic hormone with anticipatory properties, we interpret training-induced changes in overall oxytocin levels as alterations in the anticipated emotional relevance of specific events. After training socio-affective skills for three months, the stressful situation may have lost its emotional saliency, whereas the meditation technique itself gained emotional relevance. We conclude that changes in peripheral oxytocin release do not mediate stress reduction after mental training, and encourage the investigation of an allostatic concept of oxytocin in future research.</p>
Hoemberg, Brigitte	2016	Mit dem Differenziellen Inkongruenzmodell Organisationen personenzentriert entwickeln	Gesprächspsychotherapie und Personenzentrierte Beratung	47	4	217–222	<p>Der Einsatz des differentiellen Inkongruenzmodells (DIM) als Instrument für die personenzentrierte Organisationsentwicklung wird erlutert. Zunächst wird eine personenzentrierte Definition des Begriffs Organisation entwickelt und es werden Annahmen über das Selbst einer Organisation sowie ihre Selbstaktualisierung hin zum Idealbild einer "Fully functioning organization" gemacht. Krisen und Konflikte von Unternehmen werden dabei als organisationale Inkongruenzen interpretiert, die nach ihren Quellen, Formen und Ebenen differenziert werden. Anschließend wird verdeutlicht, wie diese Inkongruenzen mithilfe eines für die Einheit Organisation modifizierten DIMs differenziert werden können. Die Durchführung einer differentiellen Inkongruenzdiagnostik in der Praxis und die</p>

							Ableitung von Manahmen zur Konfliktlsung werden beschrieben.
Hoffart, Asle	2016	Cognitive models for panic disorder with agoraphobia: A study of disaggregated within-person effects	Journal of consulting and clinical psychology	84	9	839–844	Objective: The purpose of this study was to test 2 cognitive models of panic disorder with agoraphobia (PDA)—a catastrophic cognitions model and a low self-efficacy model—by examining the within-person effects of model-derived cognitive variables on subsequent anxiety symptoms. Method: Participants were 46 PDA patients with agoraphobic avoidance of moderate to severe degree who were randomly allocated to 6 weeks of either cognitive therapy, based on the catastrophic cognitions model of PDA, or guided mastery (guided exposure) therapy, based on the self-efficacy model of PDA. Cognitions and anxiety were measured weekly over the course of treatment. The data were analyzed with mixed models, using person-mean centering to disaggregate within- and between-person effects. Results: All of the studied variables changed in the expected way over the course of therapy. There was a within-person effect of physical fears, loss of control fears, social fears, and self-efficacy when alone on subsequent state anxiety. On the other hand, within-person changes in anxiety did not predict subsequent cognitions. Loss of control and social fears both predicted subsequent self-efficacy, whereas self-efficacy did not predict catastrophic cognitions. In a multipredictor analysis, within-person catastrophic cognitions still predicted subsequent anxiety, but self-efficacy when alone did not. Conclusions: Overall, the findings indicate that anxiety in PDA, at least in severe and long-standing cases, is driven by catastrophic cognitions. Thus, these cognitions seem to be useful

							therapeutic targets. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Hoffmann, Birte	2016	Der Personzentrierte Ansatz in der Arbeit mit komplex traumatisierten Menschen - ein Fallbeispiel aus der Kinder-, Jugend- und Familienhilfe	Gesprächspsychotherapie und Personzentrierte Beratung	47	1	18–22	Die personzentrierte Unterstützung komplex traumatisierter Menschen in der Kinder-, Jugend- und Familienhilfe wird verdeutlicht. Anhand der traumazentrierten Fachberatung einer 16-jährigen Jugendlichen wird aufgezeigt, inwieweit die personzentrierte Haltung der Berater hilfreich sein kann, traumatisierte Menschen mit negativen frühkindlichen Bindungserfahrungen zu unterstützen. Mit Hilfe eines Einblicks in den Beziehungsaufbau und den Beratungsverlauf werden Grundlagen eines personzentrierten und traumaspezifischen Vorgehens illustriert.
Hoffmann-Widhalm, Herta	2018	Traumafolgentherapie in der Integrativen Gestalttherapie					Die Traumafolgentherapie in der Integrativen Gestalttherapie wird im Überblick dargestellt. Nach Ausführungen zu den anthropologischen Grundlagen integrativ-gestalttherapeutisch orientierter Traumafolgentherapie, zu Trauma und Traumafolgen sowie Diagnostik wird auf folgende Aspekte und Ansätze der Traumafolgentherapie in der integrativen Gestalttherapie eingegangen: (1) die therapeutische Beziehung, (2) mehrphasige integrative Traumatherapie nach Butollo und Mitarbeitern, (3) gestalttherapeutische Grundprinzipien und Techniken in der Traumafolgentherapie, (4) Arbeit mit Selbstanteilen, (5) Eye Movement Desensitization and Reprocessing (EMDR), (6) Brainspotting, (7) Kombination von Techniken aus EMDR und Brainspotting.
Hofmann, Tony	2023	Freiräume statt Lösungen!. Ein focusingorientiertes	Person	27	1	36–48	In klar beschreibbaren Problemsituationen, für die bereits konventionelle Lösungsschemata existieren, können wir diese kreativ auf die neue Situation anwenden. Sobald sich jedoch ein Standardschema nicht mehr anwenden

		Kaskadenmodell für den professionellen Umgang mit Ungewissheit					lsst, können wir drei Stufen von Absichtslosigkeit unterscheiden: Wenn die Situation unüberschaubar wird, kann die personenzentriert-experienzielle Einzelarbeit sinnvoll sein; wenn Schemata oder einzelne Lösungsdetails in Gruppen gemeinsam neu entwickelt werden müssen, weil die Randbedingungen der Situation ins Offene diffundieren, kann experienzielle Kommunikation hilfreich sein. Und wenn in einer unüberschaubaren Situation auch Regeln und Themen fluide werden, weil nicht-kompensierbare Risiken auftauchen, kann es hilfreich sein, das Schaffen von Freiraum als Kulturtechnik zu etablieren. Die Vielschichtigkeit der Situation bestimmt also darüber, welchen Grad von Absichtslosigkeit wir wählen sollten. Das Ausmaß an Ungewissheit in einer Situation ist geschichtet und das Ausmaß an Lösungsabsicht, das wir wählen können, um dieser Situation entsprechend bewusst zu begegnen, sollte es ebenfalls sein.
Hofmeister, Beate	2020	Nachruf auf Leopold Verhelst - 30.12.1937 - 23.04.2020	Gesprächspsychotherapie und Personenzentrierte Beratung	51	2	28	Formuliert wird ein Nachruf auf Leopold Verhelst, der am 23.04.2020 verstorben ist.
Hofmeister, Beate; Hollick, Ulrike	2019	Achtsamkeitsbasierte Gesprächsführung im Gesundheitswesen	Gesprächspsychotherapie und Personenzentrierte Beratung	50	2	6-10	Grundprinzipien der Achtsamkeitsbasierten Gesprächsführung und ihr Einsatz im Gesundheitswesen werden vorgestellt. Die Wurzeln der Achtsamkeitsbasierten Gesprächsführung werden zum einen im Personenzentrierten Ansatz nach Carl Rogers und zum anderen in der buddhistischen Lehre verortet. Es wird argumentiert, dass durch diese Form der Gesprächsführung in verschiedenen Anwendungsfeldern des Gesundheitswesens einen wesentlichen Beitrag zu mehr Patientenorientierung und Resilienz im

							<p>multiprofessionellen Team geleistet werden knne. Es wird aufgezeigt und durch konkrete Beispiele illustriert, welche inneren Haltungen und kommunikativen Fertigkeiten zu entwickeln sind, um als achtsames Gegenber wirksam werden zu knnen. Zuletzt werden Fortbildungsmglichkeiten angesprochen.</p>
Holland, Jimmie C.	2018	Psycho-oncology: Overview, obstacles and opportunities	J. Psychiatr. Ment. Health Nurs. (Journal of psychiatric and mental health nursing)	27	5	1364–1376	<p>Abstract Worldwide, psychological and social issues in cancer were not the subject of scientific inquiry until the past two decades. Since then, a new subspecialty of oncology has evolved, psycho-oncology. It addresses two dimensions of cancer: the emotional responses of patients at all stages of disease, as well as their families and caretakers (psychosocial); and the psychological, social and behavioral factors that may influence cancer morbidity and mortality (psychobiological). Obstacles to development have been the facts of small numbers of clinicians and investigators worldwide and the few valid assessment instruments and research methods available to the biomedical community. These obstacles are increasingly giving way to the louder demand of the public for maximal quality of life in cancer care. Psycho-oncology is attaining subspecialty status by presently bringing a set of clinical skills in counseling, behavioral and social interventions to oncology, by providing training curricula which teach basic knowledge and skills in the area, and through creating a body of research and scholarly information about clinically relevant issues in the care of patients with cancer. Since it is increasingly recognized that psychological, social and behavioral variables influence treatment outcome, attention will likely to continue to increase. The field must meet the challenges of the 1990's in psychosocial care and availability of services, support for training clinicians and</p>

							investigators in psycho-oncology, and implementation of an exciting research agenda. The focus of new research will encourage collaborative investigations combining biological and psychosocial variables, quality of life research in clinical trials, controlled studies of psychotherapeutic, behavioral and psychopharmacologic research, and crosscultural studies that will examine differences in prevention and detection, health care systems, alternative therapies and meta analyses.
Hollick, Ulrike	2017	Zum Konzept der Familienaktualisierungstendenz	Gesprchpsych ootherapie und Personzentrierte Beratung	48	3	151-153	Der Begriff der Familienaktualisierungstendenz in der personzentrierten Psychotherapie wird vorgestellt und beleuchtet. Nach einem Einblick in die Aktualisierungstendenz bei Kurt Goldstein und Carl Rogers wird das Konzept auf Familien bertragen. Die Familienaktualisierungstendenz wird als die einer jeden Familie innewohnende Kraft und Tendenz zur Entwicklung hin zu einem gelingenden, offenen und sozialen Miteinander beschrieben.
Hollick, Ulrike	2019	Ein Pldoyer fr die Qualitt personzentrierte r Ausbildungssup ervation	Gesprchpsych ootherapie und Personzentrierte Beratung	50	2	11-17	Reflektiert wird ber die personzentrierte Ausbildungssupervision innerhalb der verschiedenen Weiterbildungsngge der Gesellschaft fr Personzentrierte Psychotherapie und Beratung e.V. (GwG). Vor dem Hintergrund persnlicher Erfahrungen wird aus Sicht einer Supervisorin der Stellenwert der Ausbildungssupervision gewrdigt. berdies werden Herausforderungen in Bezug auf Qualittskriterien, Gestaltung und Ziele von Ausbildungssupervision sowie Rolle und Qualifikation des Supervisors errtert. Es wird dafr pldiert, die genannten Aspekte auf die aktuellen Bedarfe und Gegebenheiten in den personzentrierten Weiterbildungen anzupassen und entsprechend zu verankern.
Hollick, Ulrike	2019	Zusammenarbei t mit Eltern in	Gesprchpsych ootherapie und	50	1	14-19	Beschrieben werden zu bercksichtigende Aspekte in der Zusammenarbeit mit Eltern im Rahmen einer

		der personzentrierte Psychotherapie mit Kindern und Jugendlichen	Personzentrierte Beratung				personzentrierten Psychotherapie mit Kindern und Jugendlichen. Eine eigene kleine Befragung von Eltern sowie erfahrenen und weniger erfahrenen TherapeutInnen habe ergeben, dass eine enge Zusammenarbeit mit den Eltern insgesamt als sehr zentraler Bestandteil der Therapie angesehen werde. Es sei wichtig, den Eltern Wertschätzung zu vermitteln, sie in einer Rolle als "Co-Therapeuten" zu begreifen und gemeinsam mit den Kindern und Jugendlichen Wege zu erarbeiten, wie etwa innerhalb des Familiensystems mit der Symptomatik und besonderen Belastungen umgegangen werden kann. Eine wichtige Schlussfolgerung sei, dass eine tragende Beziehung und enge Zusammenarbeit mit den Eltern letztlich dem Kind als Patienten/in helfe.
Hollick, Ulrike	2020	Bindungsorientierte Supervision	Gesprächspsychotherapie und Personzentrierte Beratung	51	3	27–36	Menschen entwickeln im Laufe der frühen Kindheit durch die Erfahrungen, die sie mit ihren primären Bezugspersonen machen, spezifische Bindungsrepräsentationen und -muster. Diese prägen auch im späteren Leben die Art, wie sie auf andere Menschen zugehen, wie sie in Belastungssituationen reagieren, Konflikte lösen und sich in Gruppen einbringen und erleben, ihre eigenen Bedürfnisse wahrnehmen und etwa mit Arbeitskollegen und Vorgesetzten bzw. Mitarbeitern umgehen. In den letzten Jahren wurde in vielen sozialen Arbeitsfeldern mehr und mehr die Bedeutung der Bindungsforschung anerkannt. Es zeigt sich, dass eine korrigierende emotionale Beziehungserfahrung dazu beitragen kann, dass Menschen mit unsicheren Bindungsmustern eine größere Bindungssicherheit entwickeln bzw. zumindest neu erworbene sichere Bindungserfahrungen neben den unsicheren bestehen können, sodass ein größeres Repertoire an Verhaltensstrategien zur Verfügung steht, um mit

							<p>herausfordernden Situationen umzugehen. Im vorliegenden Artikel sollen zunächst die Grundlagen der Bindungsforschung unter Berücksichtigung der Konzepte Feinfühligkeit und Mentalisierung dargestellt und auf die Bedeutung für unterschiedliche Settings der Supervision sowie ihre Implikationen für die Rolle des Supervisors untersucht werden. Es wird ein Supervisionskonzept entwickelt, welches unter dem Aspekt der Bindungsorientierung dazu beitragen kann, dass Supervisanden, Gruppen und Teams in ihrem beruflichen Kontext darin unterstützt werden, bei sich selbst zu reflektieren, Lösungen für ihre Anliegen zu finden und in einem gelingenden Miteinander (wieder) kreativ und explorativ tätig zu werden.</p>
Hollick, Ulrike	2023	Eigenschaften und Kompetenzen Personzentrierter Kinder- und Jugendlichenpsychotherapeuten und -berater	Gesprächspsychotherapie und Personzentrierte Beratung	54	1	20–24	<p>Die personzentrierte Beratung und Psychotherapie mit Kindern und Jugendlichen und deren Bezugspersonen stellt an den Berater und Therapeuten besondere Anforderungen. Im Folgenden wird dargestellt, welche dies sind und inwiefern sie sich auch von denen bei der Beratung und Therapie mit Erwachsenen unterscheiden. Es werden zum einen Kompetenzen beschrieben, die erforderlich sind, um den Kindern und Jugendlichen aber auch deren Eltern hilfreich und entwicklungsförderlich zu begegnen. Zum anderen werden Aspekte aufgegriffen, die für die eigene Psychohygiene bedeutsam sind. Welche Persönlichkeitsmerkmale sollte ein Weiterbildungskandidat bereits mitbringen? Welche kann und muss er entwickeln? Wie kann er darin in der Weiterbildung Unterstützung und Entwicklungsraum erfahren? Wie gelingt es, diese Kompetenzen als lebenslangen Entwicklungsprozess zu begreifen und zu begleiten? Im Artikel werden Schwerpunkte dargestellt, die im Kontext der Weiterbildung in Personenzentrierter</p>

							Beratung und Psychotherapie mit Kindern und Jugendlichen und deren Bezugspersonen sowohl aus Sicht der TeilnehmerInnen als auch aus der der Kursleitung relevant erscheinen. Der Text möchte Impulse geben und zur Diskussion anregen, was daraus für die Weiterbildung in Personenzentrierter Beratung und Psychotherapie mit Kindern und Jugendlichen und deren Bezugspersonen folgt und wie die Qualität therapeutischer Kompetenz gewährleistet und auch in der Zeit nach abgeschlossener Weiterbildung aufrechterhalten werden kann.
Holmes, Hannah J.; Thakur, Elyse R.; Carty, Jennifer N.; Ziadni, Maisa S.; Doherty, Heather K.; Lockhart, Nancy A.; Schubiner, Howard; Lumley, Mark A.	2018	Ambivalence over emotional expression and perceived social constraints as moderators of relaxation training and emotional awareness and expression training for irritable bowel syndrome	General hospital psychiatry	53		38–43	<p>OBJECTIVE Psychological treatments are generally beneficial for patients with irritable bowel syndrome (IBS), but patients' responses vary. A prior randomized controlled trial found that both relaxation training (RT) and emotional awareness and expression training (EAET) were superior to a waitlist control condition for IBS symptoms, quality of life, depression, and anxiety among IBS patients (Thakur et al., 2017).</p> <p>METHOD We conducted secondary analyses on these data to examine potential moderators of treatment outcomes. Baseline measures of patients' ambivalence over emotional expression and perceived social constraints, which have been hypothesized to influence some treatments, were tested as possible moderators of the effects of RT and EAET, compared to the control condition.</p> <p>RESULTS Results indicated that these variables moderated the effects of RT but not EAET. The benefits of RT occurred for patients who reported higher ambivalence over emotional</p>

							<p>expression or perceived social constraints, whereas the benefits of EAET were not influenced by these factors.</p> <p>CONCLUSION</p> <p>These findings suggest that RT might be particularly helpful for people who tend to avoid emotional disclosure and expression, supporting the possible benefit of targeting treatments to patient characteristics and preferences, whereas EAET might be helpful for a broader range of patients with IBS.</p>

Holt, Nicola J.	2019	The expression of schizotypy in the daily lives of artists	Psychology of Aesthetics, Creativity, and the Arts	13	3		<p>A considerable amount of research suggests that positive schizotypy (cognitive and perceptual aberrations, such as pseudohallucinations) is associated with creativity in the arts. In order to better understand how positive schizotypy might be expressed in the creative process, the experience sampling method was used to explore the experiential correlates of schizotypy in a sample of artists. Artists (N = 41) were sampled over a week-long period, answering questions at random intervals that related to mood, cognition, state of consciousness and behavior, resulting in reports on 2495 experiences. The sample scored significantly higher than normative samples on positive, but not negative, schizotypy, supporting previous research on the role of “healthy schizotypy” in creativity. Multilevel modeling demonstrated that positive schizotypy predicted a particular experiential profile in daily life, characterized by more frequent reports of the flow state, altered experience, internal dialogue, vivid imagery, distractibility, introspection, and high self-esteem. Positive schizotypy (but not other dimensions of schizotypy) was also a significant predictor of art-making and inspiration in daily life. Random intercept and slope models suggested that positive schizotypy was associated with greater increases in positive affect and self-esteem during or following art-making, supporting an “affective hypothesis” for the relationship between schizotypy and artistic involvement. This study supports previous research linking positive schizotypy with artistic creativity, and suggests that, in this context, positive schizotypy can be associated with adaptive experiences, including inspiration, flow, and self-esteem. Further, art-making may serve a therapeutic</p>

							function for artists high in positive schizotypy. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Holthoff-Detto, Vjera; Nienaber, Andr; Btel, Nora; Rapp, Michael	2021	Komplexbehandlung bei schweren psychischen Erkrankungen im Alter - Eine Positionsbestimmung	Der Nervenarzt	92	9	948-954	<p>Hintergrund. Der Hilfe-, Unterstützungs- und Pflegebedarf alter Menschen mit schweren psychischen Erkrankungen (SMI) ist sehr hoch und mit zusätzlichen altersassoziierten, somatischen Erkrankungen und Beeinträchtigungen verbunden. Alte Menschen verfolgen den Wunsch zu Hause zu bleiben und dort gepflegt werden zu können. Eine Umsiedlung in eine stationäre Pflege wird jedoch häufig wegen mangelnder Alternativen notwendig.</p> <p>Fragestellung. Wie stellt sich die gegenwärtige Behandlungsrealität in Deutschland bei alten Menschen mit SMI in der eigenen Häuslichkeit und in der stationären Pflege dar? Wie können freiheitsbeschränkende Maßnahmen in diesem Kontext vermieden werden. Material und Methode. Ausgewählte Ergebnisse der wissenschaftlichen Literatur zur psychiatrischen Versorgung alter Menschen mit SMI werden zusammengefasst und diskutiert.</p> <p>Ergebnisse. Eine aufsuchende und schweregradgestufte Komplexbehandlung steht in Deutschland in der Regelversorgung nicht zur Verfügung, da es an einer multiprofessionellen, sektorübergreifenden Vernetzungsstruktur fehlt. In den stationären Pflegeeinrichtungen in Deutschland erfahren etwa 30 % der 730.000 Bewohner freiheitsentziehenden Maßnahmen, während personenzentrierte Pflegekonzepte sowie die leitlinienkonforme und individualisierte Umsetzung nichtmedikamentöser Behandlungsstrategien und milieutherapeutischer Konzepte nicht ausreichend häufig gelingt.</p> <p>Schlussfolgerung. Es ist notwendig, in Deutschland ein nach Schweregraden gestuftes, ambulantes und aufsuchendes multiprofessionelles Versorgungs- und Behandlungsmodell für alte Menschen</p>

							mit SMI vorzuhalten, das symptombasierte und funktionsorientierte Ziele gleichzeitig verfolgen kann. Die geschützte geschlossene stationäre Pflege sollte die Funktion haben, das Leben alter Menschen in offenen Bereichen wieder zu ermöglichen. (c) Springer Medizin Verlag GmbH
Holtmaat, Karen; van der Spek, Nadia; Lissenberg-Witte, Birgit; Breitbart, William; Cuijpers, Pim; Verdonck-de Leeuw, Irma	2020	Long-term efficacy of meaning-centered group psychotherapy for cancer survivors: 2-Year follow-up results of a randomized controlled trial	Psycho-oncology	29	4	711–718	<p>OBJECTIVE Meaning-centered group psychotherapy for cancer survivors (MCGP-CS) is an effective intervention to improve personal meaning, psychological well-being, and depressive symptoms until 6 months after the intervention. In this study, the long-term effects of MCGP-CS (i.e., at 1- and 2-year follow-up) on meaning, psychological well-being and posttraumatic growth were assessed, in comparison to supportive group psychotherapy (SGP) and care as usual (CAU).</p> <p>METHODS Cancer survivors (n = 170) were randomized into MCGP-CS, SGP, or CAU. Assessments were scheduled at baseline, 1 week, 3 months, 6 months, 1 year, and 2 years postintervention. Outcome measures were the Personal Meaning Profile, Ryff's Scales of Psychological Well-Being (SPWB), the Posttraumatic Growth Inventory, and their subscales. Linear mixed models (LMM) were used and results were both reported on an intention-to-treat (ITT) basis, as well as for intervention completers only.</p> <p>RESULTS LMM and post hoc analyses with Bonferroni correction revealed that MCGP-CS participants reported more improvement on positive relations (subscale of SPWB) than CAU participants of 2-year postintervention (ITT analysis, Cohen's d = .82). Completers also reported more personal growth (subscale of SPWB) after MCGP-CS</p>

							<p>than after SGP 1-year postintervention (Cohen's $d = .94$). No long-term effects were found on the other outcome measures.</p> <p>CONCLUSIONS</p> <p>In the 2 years after MCGP-CS, the short-term significant effects on personal meaning and most positive effects related to psychological well-being faded. However, MCGP-CS had a long-term positive effect on positive relations with others and on survivors' sense of personal growth.</p> <p>TRIAL REGISTRATION</p> <p>Netherlands Trial Register: NTR3571.</p>
Holyoak, Derek; McPhee, Douglas; Hall, Greg; Fife, Stephen	2021	Microlevel Advocacy: A Common Process in Couple and Family Therapy	Family process	60	2	654–669	<p>Advocacy is an essential element to mental health practitioners' professional identity. Some scholars contend that many couple and family therapists lack the skill set needed to effectively advocate. However, these researchers often discuss advocacy solely on the macrolevel, which makes advocacy appear unidimensional and may feel out of reach for many practitioners. In this article, we argue that advocacy is not unidimensional, but consists of two levels: macro- and microlevel advocacy. Microlevel advocacy is client-centered and is effectively performed by couple and family therapists on a regular basis. By broadening the definition of advocacy to include the microlevel, we argue that advocacy is a common process of couple and family therapy that cuts across therapy models and is interwoven into the very being of a couple and family therapist. We present in this article a comprehensive case vignette to illustrate how microlevel advocacy may be performed by CFTs. Clinical and training implications are offered to help clinicians begin to bridge the gap between micro- and macrolevel advocacies.</p>

Holzberg, Oskar; Seiferth, Andrea	2018	Emotionsfokussierte Paartherapie (EFT)				Mit der Emotionsfokussierten Paartherapie (EFT) wird eine integrative Therapieform präsentiert, die die Paarbeziehung konsequent als eine Bindungsbeziehung betrachtet, in der die emotionalen Reaktionen durch die befriedigten, bedrohten oder nicht erfüllten Bindungsbedürfnisse bestimmt werden. Darüber geht das Paar in eskalierende Konflikte aus zirkulären Kommunikationsakten. Die EFT analysiert bindungstheoretisch, versteht systemisch und interveniert mit Methoden der humanistischen Psychotherapie. Im Einzelnen werden folgende Aspekte besprochen: (1) Hintergrund. (2) Indikationen, Kontraindikationen und Nebenwirkungen. (3) Klinische Praxis. (4) Empirische Befunde und kritische Einordnung.
Holzhauer, Cathryn Glanton; Gamble, Stephanie A.		Depressive symptoms mediate the relationship between changes in emotion regulation during treatment and abstinence among women with alcohol use disorders	Psychology of Addictive Behaviors	31	3	Women with alcohol use disorders (AUD) experience high rates of co-occurring conditions, such as depression and posttraumatic stress disorder (PTSD), which can complicate treatment engagement and response. Therefore, identifying factors that underlie alcohol use, depression, and PTSD symptoms in women with AUD has important treatment implications. The current study investigated emotion regulation as one such underlying factor. We tested a model that examined the extent to which changes in emotion regulation during treatment predicted women's depression and PTSD symptom severity at treatment completion and subsequent alcohol use following treatment. The study included 48 participants enrolled in a randomized controlled trial of interpersonal psychotherapy versus usual care for women with co-occurring alcohol dependence and major depression. Assessments were conducted at baseline, posttreatment (16 weeks), and follow-up (24 weeks). Descriptive statistics of baseline data revealed heightened levels of emotion dysregulation in this

							sample, which were related to fewer days abstinent from alcohol, more negative consequences from alcohol, and greater PTSD symptom severity. Women's lower depressive symptoms at the end of treatment were found to mediate the relationship between improved emotion regulation during the treatment period and greater abstinence following treatment. Posttreatment PTSD symptoms, however, were not found to mediate that relationship. These results suggest that improvements in depressive symptoms during treatment are associated with emotion regulation at the end of treatment, which may contribute to greater abstinence from alcohol following treatment. Hong, Natalie; Del Busto, Cristina T.	2020	Collaboration, scaffolding, and successive approximations: A developmental science approach to training in clinical psychology	Training and Education in Professional Psychology	14	3	228–234	As clinical psychology trainees, we have been encouraged to approach clinical work from a scientist perspective and research through the lens of what would be relevant and useful for applied clinicians. We have also been guided to assume a developmental approach, whereby both typical trajectories and individual differences in development are considered, in case conceptualization for patients, as well as our own training as developing clinical psychologists. Here, we highlight how our training model and supervisors' actions have helped to shape our clinical training through use of a junior colleague and peer-group mentoring model (Moss, Teshima, & Leszcz, 2008), as well as an adaptation of the teach-model-coach-review approach (Roberts, Kaiser, Wolfe, Bryant, & Spidalieri, 2014). Throughout our training, our supervisors have used scaffolding to encourage us to become more involved in leading therapy sessions and supervision meetings as we demonstrate competence and confidence in doing so (i.e., successive

							<p>approximations; Agras, Leitenberg, & Barlow, 1968). Working with a team of supervisors and trainees at various levels has lent itself to supporting individual differences, such that trainees are met in the space between what they can competently do independently and what they cannot do without help (e.g., “zone of proximal development;” Vygotsky, 1978). Incorporating these practices in the training of clinicians across a wide variety of settings may lead to greater positive experiences for psychology trainees and patients alike. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>
<p>Hooper, Nicholas; Johnson, Tessa; Sachs, Michael; Silverio, Alexis; Zhu, Lin; Bhimla, Aisha; Teal, Logan; Roth, Stephanie; Lagrotte, Caitlin; Stravrakis, Joyce; Arcangelo, Frank</p>	2022	<p>Comparative Efficacy of Exercise Training and Conventional Psychotherapies for Adult Depression: A Network Meta-Analysis</p>	<p>Commonhealth (Philadelphia, Pa.)</p>	3	2	47–64	<p>OBJECTIVE: An estimated 3.8% of the global population experiences depression, according to the [2019] WHO report. Evidence supports the efficacy of exercise training (EX) for depression; however, its comparative efficacy to conventional, evidence-supported psychotherapies remains understudied. Therefore, we conducted a network meta-analysis to compare the efficacy of exercise training (EX), behavioral activation therapy (BA), cognitive-behavioral therapy (CBT), and non-directive supportive therapy (NDST). METHODS: Our search was performed in seven relevant databases (inception to March 10, 2020) and targeted randomized trials comparing psychological interventions head-to-head and/or to a treatment as usual (TAU) or waitlist (WL) control for the treatment of adults (18 years or older) with depression. Included trials assessed depression using a validated psychometric tool. RESULTS: From 28,716 studies, 133 trials with 14,493 patients (mean age of 45.8 years; 71.9% female) were included. All treatment arms significantly outperformed TAU (standard mean difference [SMD] range, -0.49 to -0.95) and WL (SMD</p>

							range, -0.80 to -1.26) controls. According to surface under the cumulative ranking (SUCRA) probabilities, BA was mostly likely to have the highest efficacy (1.6), followed by CBT (1.9), EX (2.8), and NDST (3.8). Effect size estimates between BA and CBT (SMD = -0.09, 95% CI [-0.50 to 0.31]), BA and EX (-0.22, [-0.68 to 0.24]), and CBT and EX (-0.12, [-0.42 to 0.17]) were very small, suggesting comparable treatment effects of BA, CBT, and EX. With individual comparisons of EX, BA, and CBT to NDST, we found small to moderate effect sizes (0.09 to 0.46), suggesting EX, BA, and CBT may equally outperform NDST. CONCLUSIONS: Findings provide preliminary yet cautionary support for the clinical use of exercise training for adult depression. High study heterogeneity and lack of sound investigations of exercise must be considered. Continued research is needed to position exercise training as an evidence-based therapy.
Hoover, Elizabeth; McFee, Alexandra; DeDe, Gayle	2020	Efficacy of Group Conversation Intervention in Individuals with Severe Profiles of Aphasia	Seminars in speech and language	41	1	71-82	An estimated 390,000 to 520,000 individuals with severe aphasia (IWSA) currently live in the United States. IWSA experience profound social isolation, which is associated with a wide range of negative health outcomes, including mortality. Treatments for severe aphasia frequently focus on compensatory communication approaches or a discrete communication act rather than on participation-based treatment. The purpose of this study was to determine whether IWSA demonstrated improved performance on standardized language measures, patient-reported outcome measures, and connected speech samples as a result of client-centered conversation group treatment. Results of assessments conducted at pretreatment, posttreatment, and maintenance intervals were variable across participants. All participants demonstrated improvement in at least

							one of the outcome measures considered. Importantly, none of these measures fully captured how IWSA were able to convey their thoughts in supported conversation. The results lend support for the use of conversation treatment for, and for further study in, this subpopulation of individuals with aphasia.
Horton, David M.; Morrison, Blaise; Schmidt, Judy	2021	Systematized Review of Psychotherapeutic Components of Psilocybin-Assisted Psychotherapy	American journal of psychotherapy	74	4	140–149	OBJECTIVE: This systematized review sought to fill a gap in psilocybin research by investigating the structure and format of psilocybin-assisted psychotherapy (PAP), with a focus on the counseling components of the treatment. METHODS: A systematized review of PAP was conducted by using the PubMed and PsycInfo databases to search for peer-reviewed studies of human clinical trials, published within the past 25 years, in which psilocybin was administered with psychological support in a clinical setting. RESULTS: Eleven articles matched the criteria necessary for inclusion in this review. PAP was found to consist of three stages: pretreatment sessions to prepare participants for psilocybin, treatment sessions in which psilocybin was administered, and posttreatment sessions to integrate the experience with daily life. Conventional psychotherapy was primarily seen in the pre- and posttreatment sessions. Psychotherapies included in PAP differed among studies, but most often included music therapy and a nondirective supportive approach to treatment. CONCLUSIONS: This systematized review found important commonalities among clinical trials of PAP published within the past 25 years and revealed key differences among studies in psychotherapy's incorporation into PAP. Additional research is needed to identify the unique effect of psychotherapy in PAP.
Hosey, Megan M.; Ali, Mana K.;	2019	Psychology consultation	Rehabilitation Psychology		19 39-	360–365	Purpose/Objective: Intensive care unit (ICU) survivors frequently experience long-lasting mental health,

<p>Manthey, Earl C.; Albert, Kelsey; Wegener, Stephen T.; Needham, Dale M.</p>		<p>patterns in a medical intensive care unit: A brief report</p>		<p>1544(Electronic), 0090-5550(Print)</p>	<p>cognitive, and physiologic challenges. Psychologists have a role in providing interventions to reduce patient distress during critical illness and improve outcomes. There is limited data regarding psychology consultations in the ICU. This brief report characterizes psychology consultations in a medical intensive care unit (MICU) in an academic medical center. Method: Psychology consultations were prospectively tracked, with patient-related data retrospectively collected and analyzed. Results: A total of 79 consecutive psychology consultations occurred at mean of 8 ± 6 days after MICU admission. Reasons for consultation were patient emotional distress (56%), rehabilitation therapy engagement (24%), family engagement (13%), cognitive disturbance (4%), and pain (4%). Patient characteristics were: mean age 56 ± 15 years, 54% women, 53% White, and 34% with psychiatric comorbidity at MICU admission. Patients referred for consultation had a longer MICU length of stay than the total MICU population (12 ± 9 days vs. 4 ± 6 days, $p < .01$). For consultations for emotional distress compared with limited rehabilitation therapy engagement, patient demographic characteristics were similar, with the exception of women (vs. men) being more commonly consulted for emotional distress (64 vs. 26%, $p = .01$). Conclusions: Patients with a longer MICU stay more commonly had a rehabilitation psychology consultation request, typically to provide support for emotional distress or engagement in rehabilitation therapy. Future research should evaluate the effectiveness of psychology interventions in the ICU. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>

Hou, Jian-Ming; Skovholt, Thomas M.	2020	Characteristics of highly resilient therapists	Journal of Counseling Psychology	67	3	386–400	This qualitative study aimed to explore characteristics that sustain therapists' resilience over years of practice. Ten highly resilient therapists were recruited during two phases of sample screening: peer nomination and the use of quantitative scales. Data were collected through in-person interviews and analyzed using grounded theory. Results as characteristics showed that highly resilient therapists are (a) drawn to strong interpersonal relationships, (b) actively engage with self, (c) possess a core values and beliefs framework, and (d) desire to learn and grow. The authors identified a central characteristic that interlinks with each characteristic: have a strong web of vibrant connectedness. Implications for counselor resilience development, training, and supervision are discussed. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Hoyt, Michael A.; Wang, Ashley Wei-Ting; Ryan, Sean J.; Breen, Elizabeth C.; Cheavens, Jennifer S.; Nelson, Christian J.	2020	Goal-Focused Emotion-Regulation Therapy (GET) for young adult survivors of testicular cancer: a pilot randomized controlled trial of a biobehavioral intervention protocol	Trials	21	1	325	BACKGROUND Testicular cancer diagnosis and treatment, especially given its threat to sexuality and reproductive health, can be distressing in the formative period of young adulthood and the majority of young survivors experience impairing, distressing, and modifiable adverse outcomes that can persist long after medical treatment. These include psychological distress, impairment in pursuit of life goals, persistent physical side effects, elevated risk of secondary malignancies and chronic illness, and biobehavioral burden (e.g., enhanced inflammation, dysregulated diurnal stress hormones). However, few targeted interventions exist to assist young survivors in renegotiating life goals and regulating cancer-related emotions, and none focus on reducing the burden of morbidity via biobehavioral mechanisms. This paper describes the methodology of a randomized controlled

							<p>biobehavioral trial designed to investigate the feasibility and preliminary impact of a novel intervention, Goal-focused Emotion-Regulation Therapy (GET), aimed at improving distress symptoms, emotion regulation, goal navigation skills, and stress-sensitive biomarkers in young adult testicular cancer patients.</p> <p>METHODS</p> <p>Participants will be randomized to receive six sessions of GET or Individual Supportive Therapy (ISP) delivered over 8 weeks. In addition to indicators of intervention feasibility, we will measure primary (depressive and anxiety symptoms) and secondary (emotion regulation and goal navigation skills, career confusion) psychological outcomes prior to (T0), immediately after (T1), and 12 weeks after (T2) intervention. Additionally, identified biomarkers will be measured at baseline and at T2.</p> <p>DISCUSSION</p> <p>GET may have the potential to improve self-regulation across biobehavioral domains, improve overall cancer adjustment, and address the need for targeted supportive care interventions for young adult cancer survivors.</p> <p>TRIAL REGISTRATION</p> <p>Clinicaltrials.gov, NCT04150848. Registered on 28 October 2019.</p>

Hsson, Dorothea	2016	Ein Erfahrungsbericht aus der Praxis: Sina - ein traumatisiertes Kind erhält Spieltherapie	Gesprächspsychotherapie und Personenzentrierte Beratung	47	1	13-17	Anhand eines Fallbeispiel wird das personenzentrierte Vorgehen bei der Therapie von Traumatisierung geschildert. Beschrieben wird eine Spieltherapie mit einem achtjährigen Mädchen, das im Alter von vier bis sieben Jahren sexuell missbraucht und anschließend in Obhut von Verwandten gegeben wurde. Neben Belastungsfaktoren und Traumacharakteristika werden Ressourcen des Kindes sowie seine Probleme mit Grenzen, Affektkontrolle und Dissoziation dargestellt. Anschließend wird anhand von Beispielsequenzen der Therapie die Traumabewältigung im Spiel verdeutlicht. Vor diesem Hintergrund werden Grundlagen der Personenzentrierung in der Arbeit mit traumatisierten Menschen erlutert.
Hsson, Dorothea	2022	Personenzentriertes Handeln im pädagogischen Feld	Gesprächspsychotherapie und Personenzentrierte Beratung	53	3	13-17	Carl Rogers wird in erster Linie mit der Personenzentrierten Gesprächspsychotherapie und Beratung in Verbindung gebracht. Dorothea Hsson veranschaulicht in ihrem Beitrag, welche Bedeutung der Personenzentrierte Ansatz aber darüber hinaus auch in der Pädagogik hat. So findet er sich als konzeptionelle Forderung in den unterschiedlichen pädagogischen Handlungsfeldern wieder, auch wenn er dort nicht explizit erwähnt wird. Die Autorin plädiert dafür, die personenzentrierten Kernvariablen in unterschiedlichen pädagogischen Situationen anzuwenden. Dabei erhält die Authentizität der Fachkraft ein besonderes Gewicht. Besonders in Konfliktsituationen zeigt sich der Personenzentrierte Ansatz als effektive Handlungsoption, die eingebracht werden muss, damit eine Umsetzung im Sinne der personenzentrierten Haltung stattfinden kann.

Huang, Teresa Chen-Chieh; Hill, Clara E.; Strauss, Nicole; Heyman, Michelle; Hussain, Mahum	2016	Corrective relational experiences in psychodynamic -interpersonal psychotherapy: Antecedents, types, and consequences	Journal of Counseling Psychology	63	2	183-197	In posttherapy interviews with 31 clients who had recently terminated from individual open-ended psychodynamic-interpersonal psychotherapy, 18 reported having had at least 1 corrective relational experience (CRE) during psychotherapy, whereas 13 did not report any CREs. CREs typically occurred in the context of therapeutic relationships that were primarily positive but also had minor difficulties. Therapists typically facilitated CREs by identifying or questioning client behavior patterns and conveying trustworthiness. Corrective shifts for clients typically involved a new understanding of the therapy experience and variably involved gaining a new understanding of behavior patterns. Consequences generally included improvements in the therapy relationship and intrapersonal well-being. Qualitatively, the 13 non-CRE clients more frequently reported wishing the therapist's theoretical orientation was a better match than did the 18 CRE clients. Quantitatively, the CRE clients rated themselves as having more interpersonal problems at intake on the Inventory of Interpersonal Problems-32 (Barkham, Hardy, & Startup, 1996), had marginally significant improvements in interpersonal functioning over time, rated their therapy alliances higher on the Working Alliance Inventory-Short Revised (Hatcher & Gillaspay, 2006) midtherapy, and rated their therapy alliances higher over time compared with the non-CRE clients. Implications for practice and research are discussed. (PsycINFO Database Record (c) 2016 APA, all rights reserved)
Huang, Xiaying; Wu, Haihua	2022	Effect of Predictive Nursing Combined with	Applied bionics and biomechanics	2022		4159085	To explore the influence of predictive nursing combined with emotional therapy on the rehabilitation effect and psychological state of patients with brain injury after the operation and to analyze its application value to patients

		Emotional Therapy on Rehabilitation Effect and Psychological State of Patients with Brain Injury after the Operation					<p>with brain injury after the operation. Methods. 70 postoperative patients with brain injury who went to our hospital for diagnosis and treatment were selected as the key figures of this experiment, including 31 female patients and 39 male patients. In order to ensure the uniformity of data, medical staff need to divide patients into an experimental group and a control group through the double-blind method, with 35 cases in each group. The patients in the two groups need to take the relevant diagnosis and surgical treatment measures after admission. The patients in the control group take routine nursing, providing patients with a clean and tidy ward is convenient for patients to manage nursing, and for patients to bring comfortable treatment relief. The patients in the experimental group take predictive nursing combined with emotional therapy, which is to master the basic situation of patients, according to the quality of patients, and develop comprehensive nursing measures for patients. The psychological status, complication incidence rate, treatment effectiveness, and nursing satisfaction of the two groups were compared and analyzed. Results. The psychological status, complication incidence rate, nursing efficiency, and nursing satisfaction of patients in the experimental group were significantly better than those in the control group ($P < 0.05$). Conclusion. Predictive nursing combined with emotional therapy for patients with brain injury after the operation can effectively alleviate bad mood of patients, reduce the incidence rate of complications, improve the nursing satisfaction of patients, as well as provide patients with high-quality treatment and nursing services. It has a certain clinical application value and is worth popularizing.</p>

<p>Huber, Julia; Born, Ann-Kathrin; Claab, Christine; Ehrental, Johannes C.; Nikendei, Christoph; Schauenburg, Henning; Dinger, Ulrike</p>	<p>2019</p>	<p>Therapeutic agency, in-session behavior, and patient-therapist interaction</p>	<p>Journal of clinical psychology</p>	<p>75</p>	<p>1</p>	<p>66–78</p>	<p>OBJECTIVE The aim of this study was to investigate associations between patients' subjective agency, their observable in-session behavior, and the patient-therapist interaction during the early phase of psychotherapy.</p> <p>METHODS The sample included 52 depressed patients in psychodynamic psychotherapy. After Session 5, the patients' agency and the quality of the therapeutic alliance were assessed. Based on session recordings, two independent observers rated the patients' involvement, their interpersonal behavior, and the therapists' directiveness.</p> <p>RESULTS Higher agency was associated with stronger therapeutic alliances. Patients who indicated higher agency in their therapy participated more actively in the session and showed less hostile impact messages. Patients' agency was not related to therapists' directiveness.</p> <p>CONCLUSIONS Patients' sense of agency in psychotherapy was associated with more active involvement and affiliative interaction. The findings support the idea that patients need to feel capable of acting within and having an influence on their therapy to benefit from it.</p>
<p>Huggett, Charlotte; Gooding, Patricia; Haddock, Gillian; Quigley, Jody; Pratt, Daniel</p>	<p>2022</p>	<p>The relationship between the therapeutic alliance in psychotherapy and suicidal experiences: A</p>	<p>Clinical psychology & psychotherapy</p>	<p>29</p>	<p>4</p>	<p>1203–1235</p>	<p>Abstract It is well established that there is a fundamental need to develop a robust therapeutic alliance to achieve positive outcomes in psychotherapy. However, little is known as to how this applies to psychotherapies which reduce suicidal experiences. The current narrative review summarizes the literature which investigates the relationship between the therapeutic alliance in psychotherapy and a range of suicidal experiences prior</p>

		systematic review					to, during and following psychotherapy. Systematic searches of MEDLINE, PsycINFO, Web of Science, EMBASE and British Nursing Index were conducted. The search returned 6472 studies, of which 19 studies were eligible for the present review. Findings failed to demonstrate a clear link between suicidal experiences prior to or during psychotherapy and the subsequent development and maintenance of the therapeutic alliance during psychotherapy. However, a robust therapeutic alliance reported early on in psychotherapy was related to a subsequent reduction in suicidal ideation and attempts. Study heterogeneity, varied sample sizes and inconsistent reporting may limit the generalizability of review findings. Several recommendations are made for future psychotherapy research studies. Training and supervision of therapists should not only highlight the importance of developing and maintaining the therapeutic alliance in psychotherapy when working with people with suicidal experiences but also attune to client perceptions of relationships and concerns about discussing suicidal experiences during therapy.
Hughes, Daniel	2017	Dyadic Developmental Psychotherapy (DDP): An Attachment-focused Family Treatment for Developmental Trauma	ANZ J of Family Therapy (Australian and New Zealand Journal of Family Therapy)	38	4	595–605	
Hughes, Elizabeth K.; Sawyer, Susan	2019	Predictors of early response in conjoint and	European eating disorders review : the journal of	27	3	283–294	OBJECTIVE Early response, as indicated by early weight gain, in family-based treatment (FBT) for adolescent anorexia

M.; Accurso, Erin C.; Singh, Simar; Le Grange, Daniel		separated models of family-based treatment for adolescent anorexia nervosa	the Eating Disorders Association				<p>nervosa (AN) predicts remission at end of treatment. However, little is known about what factors contribute to early response. Further, no previous studies have examined early response to separated forms of FBT.</p> <p>METHOD</p> <p>Data from a randomised clinical trial of conjoint FBT and separated FBT (parent-focused treatment, PFT) were analysed to examine the timing and amount of early weight gain that predicted remission and identify factors associated with early response.</p> <p>RESULTS</p> <p>Weight gain of at least 2.80 kg in FBT (N = 55) and 2.28 kg in PFT (N = 51), by Session 5, were the best predictors of remission at end of treatment. Early response in FBT was predicted by greater paternal therapeutic alliance and lower paternal criticism. Early response in PFT was predicted by less severe eating-disorder symptoms and negative affect at baseline, lower maternal criticism, and greater adolescent therapeutic alliance.</p> <p>CONCLUSIONS</p> <p>The results confirm that early weight gain is an important prognostic indicator in both conjoint FBT and PFT and suggest that addressing negative emotion, parental criticism, and therapeutic alliance early in treatment could improve remission rates.</p>
Hull, Alastair M.; Corrigan, Frank M.	2019	The Comprehensive Resource Model®: Overview of basic affects in adversity & effective	Scand J Med Sci Sports (Scandinavian Journal of Medicine & Science in Sports)	19	2	130-137	<p>Abstract Much of the theoretical focus in post-traumatic stress disorder has been on the role of the amygdala, the hippocampus and the prefrontal cortex. Crucially, in unresolved traumatic experiences that underlie clinical presentations, this focus misses the brain areas key to the defence responses of fight, flight and freeze?and the associated affects of anger, fear and grief. The periaqueductal gray in the midbrain, with the</p>

		treatment for complex reactions to trauma					<p>hypothalamus, is essential for these somatic and emotional responses to traumatic experiences. We argue that when treatment approaches thought to work at the higher brain levels have been ineffective, it is because they have failed to engage the midbrain and hypothalamic sources of the affective responses to the trauma and to the memory of it. Basic affects have been so overwhelming that dissociation, or a similarly protective neurochemical capping mechanism, has prevented full resolution of the affective content of the adversity. Treatment with the Comprehensive Resource Model? (CRM) aims to clear the clinically relevant residues of adverse experiences by resolving the emotional responses accessed through the body memories. When the trauma has led to overwhelming distress, and/or dissociation, there is a necessity for robust resourcing to be in place before the emotional intensity of that distress is accessed. Resourcing needs to be as proximal to the re-experience as possible to promote complete resolution and in some psychotherapy modalities, the supports provided are somewhat remote from the crucial moments of processing. Therefore, we describe how the CRM seeks to have robustly resourced states present concurrently with traumatised states to avoid overwhelming emotional distress. This allows safe entry into the deepest pain residual from the traumatic event so that it is not overwhelming during processing of the memory, and does not lead to further dissociation, allowing the individual to remain fully present throughout. This ?stepping into the affect? can then be so rapidly effective that we also argue that CRM is not an exposure treatment; re-orientation to the deepest content of the experience resolves the residual distress quickly and</p>
--	--	---	--	--	--	--	--

							permanently through memory reconsolidation. Re-learning at upper brain levels will then follow from the revoking of the affective power, which has previously driven stimulus/context and response learning in the amygdala, hippocampus and prefrontal cortex.
Hume, Romy	2022	Show Me the Real You: Enhanced Expression of Rogerian Conditions in Therapeutic Relationship Building with Autistic Adults	Autism in adulthood : challenges and management	4	2	151-163	BACKGROUND: Research in psychotherapy and counseling theory has shown the importance of a strong therapeutic relationship. However, in the context of working with autistic adults, the relationship appears to be de-emphasized, or "different approaches" are recommended without specifying these. Neglect of relationship building may contribute to autistic adults' negative experiences with health care professionals identified in previous studies. METHODS: I interviewed 17 autistic adults about their relationship building experiences with a wide range of professionals primarily from mental and medical health backgrounds. I also interviewed two mental health counselors and one psychologist who had experience working with this client group and had been recommended by autistic participants. I elicited best practice recommendations from all participants. I analyzed the data in an interpretive-interactionist framework and present them through creative analytic practice. FINDINGS: I address one major theme in this article: the importance of Rogerian/person-centered relationship conditions. All had to be practiced in an enhanced way: (1) Enhanced congruence could be demonstrated through therapist self-disclosure and refraining from phony relationship building "techniques" such as vocal adjustments. (2) Enhanced empathy could be demonstrated through genuine listening and accurate interpretation; however, interpretation needed to be phrased tentatively. (3)

							Enhanced unconditional positive regard could be demonstrated through explicit verbal expression, practical demonstration, and remembering. CONCLUSIONS: Results largely mirrored research with non-autistic populations: different approaches were not needed for relationship building. Participants emphasized the importance of Rogers' person-centered conditions and described pivotal relationship building moments associated with enhanced expression of these conditions.
Hundt, Natalie E.; Helm, Ashley; Smith, Tracey L.; Lamkin, Joanna; Cully, Jeffrey A.; Stanley, Melinda A.	2018	Failure to engage: A qualitative study of veterans who decline evidence-based psychotherapies for PTSD	Psychological Services	15	4	536–542	Low engagement in posttraumatic stress disorder (PTSD) psychotherapy is a common problem in the U.S. Department of Veteran Affairs (VA), with up to half of veterans who are referred to an evidence-based psychotherapy failing to engage in that treatment. Prior research has focused on identifying general barriers to mental health treatment rather than barriers specific to evidence-based treatments for PTSD. The purpose of the current study was to identify barriers for veterans who referred specifically for evidence-based psychotherapy (i.e., cognitive processing therapy or prolonged exposure) but who did not attend any sessions of those psychotherapies. Qualitative interviews (N = 24) were used to gain a better understanding of the experiences and attitudes of these veterans. Most veterans reported multiple barriers to treatment engagement (M = 4.2 barriers), suggesting that an accumulation of barriers contributes to poor engagement. Barriers fell into 5 categories: practical, knowledge, emotional, therapy-related, and VA-system-related. The most-endorsed category, mentioned by two thirds of the sample, was VA-system-related barriers, including inefficiencies and delays, negative experiences with VA staff and providers,

							discomfort with the VA environment, and difficulty navigating the VA system. Veterans' experienced barriers to beginning PE and CPT were diverse but, overall, highlighted the need to transform the VA to a more patient-centered model of care. (PsycINFO Database Record (c) 2018 APA, all rights reserved)
Hundt, Natalie E.; Smith, Tracey L.; Fortney, John C.; Cully, Jeffrey A.; Stanley, Melinda A.	2019	A qualitative study of veterans' mixed emotional reactions to receiving a PTSD diagnosis	Psychological Services		19 39- 14 8X(Ele ctr oni c), 15 41- 15 59(Pri nt)	687-692	Many veterans do not engage in needed mental health care. To address this problem, we need to understand these patients' experiences from the very start of their care, which includes the assessment and diagnosis process and the communication of that diagnosis to the patient. The patient's reaction to this process can set the tone for the patient's relationship with the mental health system and his or her therapist, yet therapists often receive little training in how to most effectively provide a diagnosis to patients. Prior research has examined emotional reactions to receiving a psychotic spectrum diagnosis, which sometimes included both positive and negative reactions, but to the authors' knowledge, no work has examined reactions to receiving a posttraumatic stress disorder (PTSD) diagnosis. This qualitative study expands upon that work by examining common reactions to receipt of a PTSD diagnosis among low treatment-engaging veterans, changes in that reaction over the first few weeks postdiagnosis, and differences among reactions across veterans who initiate versus refuse evidence-based psychotherapy. Among 50 participants, self-reported reactions were categorized as positive, neutral, and negative. Positive reactions included validation, hope, and proactivity; neutral reactions included confusion, uncertainty, and acceptance; and negative reactions included shock, denial, and fear of stigma. We discuss recommendations for therapists in

						providing diagnoses in a patient-centered, cognitive-behavioral therapy-consistent way, to maximize the chances of engaging patients into mental health care. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Hunt, G. E.; Siegfried, N.; Morley, K.; Brooke-Sumner, C.; Cleary, M.	2019	Psychosocial interventions for people with both severe mental illness and substance misuse	Cochrane Database of Systematic Reviews	12(12):CD010888. doi:10.1002/14651858.cd010888.pub4	12	Abstract - Background Even low levels of substance misuse by people with a severe mental illness can have detrimental effects. Objectives To assess the effects of psychosocial interventions for reduction in substance use in people with a serious mental illness compared with standard care. Search methods The Information Specialist of the Cochrane Schizophrenia Group (CSG) searched the CSG Trials Register (2 May 2018), which is based on regular searches of major medical and scientific databases. Selection criteria We included all randomised controlled trials (RCTs) comparing psychosocial interventions for substance misuse with standard care in people with serious mental illness. Data collection and analysis Review authors independently selected studies, extracted data and appraised study quality. For binary outcomes, we calculated standard estimates of risk ratio (RR) and their 95% confidence intervals (CIs) on an intention-to-treat basis. For continuous outcomes, we calculated the mean difference (MD) between groups. Where meta-analyses were possible, we pooled data using a random-effects model. Using the GRADE approach, we identified seven patient-centred outcomes and assessed the quality of evidence for these within each comparison. Main results Our review now includes 41 trials with a total of 4024 participants. We have identified nine comparisons within the included trials and present a summary of our main findings for seven of these below. We were unable to summarise many findings due

						<p>to skewed data or because trials did not measure the outcome of interest. In general, evidence was rated as low- or very-low quality due to high or unclear risks of bias because of poor trial methods, or inadequately reported methods, and imprecision due to small sample sizes, low event rates and wide confidence intervals. 1. Integrated models of care versus standard care (36 months) No clear differences were found between treatment groups for loss to treatment (RR 1.09, 95% CI 0.82 to 1.45; participants = 603; studies = 3; low-quality evidence), death (RR 1.18, 95% CI 0.39 to 3.57; participants = 421; studies = 2; low-quality evidence), alcohol use (RR 1.15, 95% CI 0.84 to 1.56; participants = 143; studies = 1; low-quality evidence), substance use (drug) (RR 0.89, 95% CI 0.63 to 1.25; participants = 85; studies = 1; low-quality evidence), global assessment of functioning (GAF) scores (MD 0.40, 95% CI -2.47 to 3.27; participants = 170; studies = 1; low-quality evidence), or general life satisfaction (QOLI) scores (MD 0.10, 95% CI -0.18 to 0.38; participants = 373; studies = 2; moderate-quality evidence). 2. Non-integrated models of care versus standard care There was no clear difference between treatment groups for numbers lost to treatment at 12 months (RR 1.21, 95% CI 0.73 to 1.99; participants = 134; studies = 3; very low-quality evidence). 3. Cognitive behavioural therapy (CBT) versus standard care There was no clear difference between treatment groups for numbers lost to treatment at three months (RR 1.12, 95% CI 0.44 to 2.86; participants = 152; studies = 2; low-quality evidence), cannabis use at six months (RR 1.30, 95% CI 0.79 to 2.15; participants = 47; studies = 1; very low-quality evidence) or mental state insight (IS) scores by three months (MD 0.52, 95% CI -0.78 to 1.82;</p>
--	--	--	--	--	--	---

						<p>participants = 105; studies = 1; low-quality evidence). 4. Contingency management versus standard care We found no clear differences between treatment groups for numbers lost to treatment at three months (RR 1.55, 95% CI 1.13 to 2.11; participants = 255; studies = 2; moderate-quality evidence), number of stimulant positive urine tests at six months (RR 0.83, 95% CI 0.65 to 1.06; participants = 176; studies = 1) or hospitalisations (RR 0.21, 95% CI 0.05 to 0.93; participants = 176; studies = 1); both low-quality evidence . 5. Motivational interviewing (MI) versus standard care We found no clear differences between treatment groups for numbers lost to treatment at six months (RR 1.71, 95% CI 0.63 to 4.64; participants = 62; studies = 1). A clear difference, favouring MI, was observed for abstaining from alcohol (RR 0.36, 95% CI 0.17 to 0.75; participants = 28; studies = 1) but not other substances (MD -0.07, 95% CI -0.56 to 0.42; participants = 89; studies = 1), and no differences were observed in mental state general severity (SCL-90-R) scores (MD -0.19, 95% CI -0.59 to 0.21; participants = 30; studies = 1). All very low-quality evidence. 6. Skills training versus standard care At 12 months, there were no clear differences between treatment groups for numbers lost to treatment (RR 1.42, 95% CI 0.20 to 10.10; participants = 122; studies = 3) or death (RR 0.15, 95% CI 0.02 to 1.42; participants = 121; studies = 1) . Very low-quality, and low-quality evidence, respectively. 7. CBT + MI versus standard care At 12 months, there was no clear difference between treatment groups for numbers lost to treatment (RR 0.99, 95% CI 0.62 to 1.59; participants = 327; studies = 1; low-quality evidence), number of deaths (RR 0.60, 95% CI 0.20 to 1.76; participants = 603; studies = 4; low-quality evidence), relapse (RR 0.50, 95% CI 0.24 to 1.04;</p>
--	--	--	--	--	--	---

						<p>participants = 36; studies = 1; very low-quality evidence), or GAF scores (MD 1.24, 95% CI -1.86 to 4.34; participants = 445; studies = 4; very low-quality evidence). There was also no clear difference in reduction of drug use by six months (MD 0.19, 95% CI -0.22 to 0.60; participants = 119; studies = 1; low-quality evidence). Authors' conclusions We included 41 RCTs but were unable to use much data for analyses. There is currently no high-quality evidence to support any one psychosocial treatment over standard care for important outcomes such as remaining in treatment, reduction in substance use or improving mental or global state in people with serious mental illnesses and substance misuse. Furthermore, methodological difficulties exist which hinder pooling and interpreting results. Further high-quality trials are required which address these concerns and improve the evidence in this important area. Plain language summary Psychosocial interventions for people with both severe mental illness and substance misuse. What is the aim of this review? The aim of this Cochrane Review is to find out if psychosocial interventions aimed at reducing substance abuse in people with a serious mental illness improve patient outcomes compared to standard care. Researchers in the Cochrane collected and analysed all relevant studies that randomly allocated people with severe mental illness and substance misuse to a psychosocial treatment or standard care to answer this question and found 41 relevant studies. Key message From these 41 studies we did not find any high-quality evidence to support any one psychosocial intervention over standard care. However, the differences in study designs made comparisons between studies problematic. What was studied in the review? “Dual”</p>
--	--	--	--	--	--	--

						<p>diagnosis is the term used to describe people who have a mental health problem and also have problems with drugs or alcohol. In some areas, over 50% of all those with a serious mental illness (these include schizophrenia, bipolar disorders and major depression) will have problems with drugs or alcohol that have negative and damaging effects on the illness symptoms and the way their medication works. People who have substance misuse problems can be treated via a variety of psychosocial interventions. These include motivational interviewing, or MI, that looks at people's motivation for change; cognitive behavioural therapy, or CBT, which helps people adapt their behaviour by improving coping strategies; contingency management which rewards patients to abstain from taking substances, psycho-education for patients and their carers or family, group and individual skills training. Other interventions include provider-oriented long-term interventions unifying services to provide integrated treatment so patients do not have to negotiate separate mental health and substance abuse treatment programmes. Integrated care is often linked to assertive community treatment (ACT) for patients with a dual diagnosis. There are a variety of psychosocial interventions that can be added to routine care and these can be provided individually or in various combinations. Currently, we do not know if any psychosocial treatment is better or worse than standard care or if they work better given in combination or individually. What are the main results of the review? The review found 41 relevant studies with a total of 4024 people. These studies looked at a variety of different psychosocial interventions (including CBT, MI, skills training, integrated models of care and contingency</p>
--	--	--	--	--	--	---

							management) and compared them to standard care (the care a participant in the trial would normally receive). Main results showed there was: 1. no real difference in terms of numbers lost to treatment (low-quality evidence); 2. no real difference in terms of death (low-quality evidence); 3. no real difference in alcohol or substance used (low-quality evidence); 4. no real difference in global functioning or general life satisfaction (low- to moderate-quality evidence). In addition, studies had high numbers of people leaving early, differences in outcomes measured, and differing ways in which psychosocial interventions were delivered. More large-scale, high-quality and better reported studies are required to address these shortcomings. This will better address whether psychosocial interventions are effective for people with serious mental illness and substance misuse problems. How up-to-date is this review? The review authors searched for studies that had been published up to October 2018.
Hunter, Leah J.; DiPerna, James C.; Hart, Susan Crandall; Crowley, Max	2018	At what cost? Examining the cost effectiveness of a universal social-emotional learning program	School Psychology Quarterly	33	1	147-154	Although implementation of universal social-emotional learning programs is becoming more common in schools, few studies have examined the cost-effectiveness of such programs. As such, the purpose of this article is two fold. First, we provide an overview of cost-effectiveness methods for school-based programs, and second, we share results of a cost-effectiveness analysis (CEA) of a universal social-emotional learning (SEL) program, the Social Skills Improvement System—Classwide Intervention Program (SSIS-CIP; Elliott & Gresham, 2007). Specifically, we compared the cost-effectiveness of SSIS-CIP implementation across first- and second-grade classrooms, and results indicated that second grade is the more cost-effective option for implementing the SSIS-

							CIP. Several considerations are discussed regarding cost-effectiveness analysis of universal SEL programs as well as the importance of using CEA results to inform programming decisions. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Hurley, John; Lakeman, Richard; Linsley, Paul; Ramsay, Mike; Mckenna-Lawson, Stephen	2022	Utilizing the mental health nursing workforce: A scoping review of mental health nursing clinical roles and identities	Int J Mental Health Nurs (International Journal of Mental Health Nursing)	31	4	796-822	Abstract Despite rising international needs for mental health practitioners, the mental health nursing workforce is underutilized. This is in part due to limited understandings of their roles, identities, and capabilities. This paper aimed to collate and synthesize published research on the clinical roles of mental health nurses in order to systematically clarify their professional identity and potential. We searched for eligible studies, published between 2001 and 2021, in five electronic databases. Abstracts of retrieved studies were independently screened against exclusion and inclusion criteria (primarily that studies reported on the outcomes associated with mental health nursing roles). Decisions of whether to include studies were through researcher consensus guided by the criteria. The search yielded 324 records, of which 47 were included. Retained papers primarily focused on three themes related to mental health nursing clinical roles and capabilities. Technical roles included those associated with psychotherapy, consumer safety, and diagnosis. Non-technical roles and capabilities were also described. These included emotional intelligence, advanced communication, and reduction of power differentials. Thirdly, the retained papers reported the generative contexts that influenced clinical roles. These included prolonged proximity with consumers with tensions between therapeutic and custodial roles. The results of this scoping review suggest the mental health nurses (MHNs) have a wide scope of

							technical skills which they employ in clinical practice. These roles are informed by a distinctive cluster of non-technical capabilities to promote the well-being of service users. They are an adaptable and underutilized component of the mental health workforce in a context of escalating unmet needs for expert mental health care.
Huston, Jonathan; Meier, Scott; Faith, Myles; Reynolds, Amy	2019	Exploratory study of automated linguistic analysis for progress monitoring and outcome assessment	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	3	321–328	Abstract Objective The most successful approach to dealing with treatment failure employs progress monitoring and outcome assessment (PMOA) measures that enable clinicians to identify clients who are failing to progress. On the basis of previous research indicating that word use relates to individuals' psychological characteristics as well as clinical outcomes, we investigated automated linguistic analysis of client speech as an alternative PMOA approach. Methods We employed the Linguistic Inquiry and Word Count (LIWC) program to study the language of a subset of 12 clients from the York I Depression Study. Automated analyses examined transcripts of 24 individual psychotherapy sessions, one early in treatment (T1) and one late in treatment (T2), split between six good and six poor outcome cases. Results Good outcomes were associated with more positive emotion words and fewer past focus words and negation words at T1. Logistic regression models predicted good versus poor treatment outcome for 70%–82% of transcripts. However, analyses failed to support the hypothesis that language use patterns changed from T1 to T2 during the course of therapy. Conclusions Clinicians have been slow to adopt PMOA measures as part of routine practice, partially as a result of additional paperwork and time burdens. Automated analysis of client language provides one alternative method for decreasing client and therapist workload. This

							study's results, while mixed, provide evidence that additional research should be conducted to investigate the potential for LIWC and other automated measures to provide PMOA data for clinical feedback.

Hutterer-Krisch, Renate	2018	Frustrationen als Chance - Paardynamische Beitrge der Integrativen Gestalttherapie					Paardynamische Beitrge der Integrativen Gestalttherapie werden unter besonderer Bercksichtigung von Frustrationen der Paardynamik dargestellt. Zentrale Aspekte sind paardynamische Risikofaktoren wie Angst und Ohnmacht. Beschrieben werden zunchst Konzepte und Interventionen nach J. Zinker, insbesondere Gestaltzyklus und interaktiver Zyklus. Eingegangen wird dabei auf die Phase der Bewusstheit und Strungen in der Bewusstheitsphase, auf die Phase der Energie/Aktion und Strungen in der Energie-/Aktionsphase, auf die Phase des Kontakts und Strungen in der Kontaktphase, auf die Phase der Resolution/Abschluss, auf die Phase des Rckzugs und Strungen in der Rckzugsphase sowie auf die spezifischen Indikationen in den genannten Phasen. Anschlieend werden verinnerlichte Paarbeziehungsmuster nach A. Teachworth und die Selbstorganisation und Paardynamik nach H. Beaumont besprochen.
Huxley, Elizabeth; Lewis, Kate L.; Coates, Adam	2019	Evaluation of a brief intervention within a stepped	BMC psychiatry	19	1	341	BACKGROUND: Although there is growing evidence that stepped models of care are useful for providing appropriate, person centered care, there are very few studies applied to personality disorders. A brief, four

<p>D.; Borg, Wayne M.; Miller, Caitlin E.; Townsend, Michelle L.; Grenyer, Brin F. S.</p>		<p>care whole of service model for personality disorder</p>				<p>session, psychological treatment intervention for personality disorder within a whole of service stepped care model was evaluated. The intervention stepped between acute emergency crisis mental health services and longer-term outpatient treatments. METHODS: Study 1 used service utilization data from 191 individuals referred to the brief intervention at a single community health site in a metropolitan health service. Proportions of individuals retained across the intervention and the referral pathways accessed following the intervention were examined. Study 2 examined 67 individuals referred to the brief intervention across 4 different sites in metropolitan health services. A range of measures of symptoms and quality of life were administered at the first and last session of the intervention. Effect sizes were calculated to examine mean changes across the course of the intervention. RESULTS: Study 1 found that 84.29% of individuals referred to the intervention attended at least 1 session, 60.21% attended 2 sessions or more and 41.89% attended 3 or more sessions. 13.61% of the sample required their care to be "stepped up" within the service, whereas 29.31% were referred to other treatment providers following referral to the intervention. Study 2 found a significant reduction in borderline personality disorder symptom severity and distress following the intervention, and an increase in quality of life. The largest reduction was found for suicidal ideation (d = 1.01). CONCLUSIONS: Brief psychological intervention was a useful step between acute services and longer-term treatments in this stepped model of care for personality disorder. Suicide risk and symptom severity reduced and quality of life improved, with only a small proportion of</p>
---	--	---	--	--	--	---

							individuals requiring ongoing support from the health service following the intervention.
Hwang, Youngsub; Kwon, Jeong-Yi; Cho, Joongbum; Choi, Jaeyoung	2023	Individualized Goal Setting for Pediatric Intensive Care Unit-Based Rehabilitation Using the Canadian Occupational Performance Measure	Children (Basel, Switzerland)	10	6		The Canadian Occupational Performance Measure (COPM) is a client-centered outcome measure that facilitates the prioritization of individualized interventions. Given the rising emphasis on individualized intervention in pediatric intensive care units (PICUs), this cross-sectional study aimed to explore caregivers' perspectives on their children's functional goals within PICUs. From 1 September 2020 to 26 June 2022, caregivers of 41 children aged 1-18 years completed the COPM within 48 h of PICU admission. The study also explored the clinical variables predicting a high number of occupational performance goals ($\geq 4/5$). Out of 190 goals proposed by caregivers, 87 (45.8%) pertained to occupational performance, while 103 (54.2%) were related to personal factors. Among the occupational performance goals, the majority were associated with functional mobility (55; 28.9%), followed by personal care (29; 15.2%) and quiet recreation (3; 1.6%). Among personal goals, physiological factors (68; 35.8%) were most common, followed by physical factors (35; 18.4%). We found caregiver anxiety, measured by the State-Trait Anxiety Inventory-State, to be a significant predictor of the number of occupational performance goals. These findings underscore the importance of caregiver psychological assessment in the PICU to facilitate personalized goal setting and improve rehabilitation outcomes.
Hynie, Michaela; Jaimes, Annie; Oda, Anna;	2022	Assessing Virtual Mental Health Access for Refugees	International journal of environmental	19	9		During the COVID-19 pandemic, mental health services rapidly transitioned to virtual care. Although such services can improve access for underserved populations, they may also present unique challenges,

Rivest-Beauregard, Marjolaine; Perez Gonzalez, Laura; Ives, Nicole; Ahmad, Farah; Kuo, Ben C. H.; Arya, Neil; Bokore, Nimo; McKenzie, Kwame		during the COVID-19 Pandemic Using the Levesque Client-Centered Framework: What Have We Learned and How Will We Plan for the Future?	research and public health				especially for refugee newcomers. This study examined the multidimensional nature of access to virtual mental health (VMH) care for refugee newcomers during the COVID-19 pandemic, using Levesque et al.'s Client-Centered Framework for Assessing Access to Health Care. One hundred and eight structured and semi structured interviews were conducted in four Canadian provinces (8 community leaders, 37 newcomer clients, 63 mental health or service providers or managers). Deductive qualitative analysis, based on the Client-Centered Framework, identified several overarching themes: challenges due to the cost and complexity of using technology; comfort for VMH outside clinical settings; sustainability post-COVID-19; and communication and the therapeutic alliance. Mental health organizations, community organizations, and service providers can improve access to (virtual) mental health care for refugee newcomers by addressing cultural and structural barriers, tailoring services, and offering choice and flexibility to newcomers.
Ibrahim, Maliha; Levy, Suzanne; Gallop, Bob; Krauthamer Ewing, Stephanie; Hogue, Aaron; Chou, Jessica; Diamond, Guy	2022	Therapist Adherence to Two Treatments for Adolescent Suicide Risk: Association to Outcomes and Role of Therapeutic Alliance	Family process	61	1	183-197	In psychotherapy research, adherence refers to the extent to which therapists deliver a treatment as intended. This study examined whether therapist adherence to two different manualized treatments was associated with improved client outcomes and whether the association was moderated by therapeutic alliance. The study sample included 320 video recordings of therapy sessions from 118 cases in a randomized controlled trial (RCT) comparing attachment-based family therapy (ABFT) with family-enhanced nondirective supportive therapy (FE-NST). Recordings were selected from early, middle, and late stages of treatment. The adherence measure consisted of 24 items representing essential therapist

							<p>interventions from both treatments. Trained raters coded tapes from both therapies. Adolescent self-report of alliance was measured at session 4. Adherence to ABFT was associated with a significant increase in family cohesion at mid-treatment but not at posttreatment. Adherence to FE-NST was significantly associated with an increase in suicide ideation posttreatment. Using therapeutic alliance as a moderator, adherence to ABFT was significantly associated with a reduction in suicide ideation, family conflict, and higher client satisfaction posttreatment. Alliance did not positively affect the association of FE-NST adherence to outcomes. Findings suggest that adherence to ABFT interventions may be better linked to treatment outcomes when adolescents feel a strong alliance with their therapist. Implications for future research and therapist training are explored.</p>
Ihara, Emily S.; Tompkins, Catherine J.; Inoue, Megumi; Sonneman, Sonya	2019	Results from a person-centered music intervention for individuals living with dementia	Geriatrics & gerontology international	19	1	30–34	<p>AIM: Dementia is a chronic, costly disease affecting millions of people worldwide. Effective, affordable person-centered interventions are required to improve the lived experiences of individuals with dementia and their caregivers in various care settings. The present study examined the effects of a person-centered music listening intervention on mood, agitation and social engagement for individuals living with dementia.</p> <p>METHODS: This quasi-experimental study was carried out with participants at five community-based adult day health centers (n = 51). Standardized instruments were used to measure mood and agitation, and in-person and video-recorded observations of participant behavior were used to analyze changes before, during and after the intervention across four domains: mood, agitation, connecting to music and engaging socially. Within-person differences were examined using the Wilcoxon signed</p>

							rank test, and between-group differences were examined using the Mann-Whitney U-test. RESULTS: Although standardized instruments did not yield statistically significant results, the behavioral observations showed a positive change in mood and a decrease in agitation. From pre- to post-intervention, there were statistically significant increases in joy, eye contact, eye movement, being engaged and talkativeness, and a decrease in sleeping and moving or dancing. CONCLUSIONS: Behavioral observations show the positive impact a person-centered music listening intervention might have on individuals living with dementia and attending adult day health centers. This affordable intervention provides a useful tool for caregivers that might improve the day-to-day experience of individuals living with dementia. Geriatr Gerontol Int 2019; 19: 30-34.
Ikemi, Akira	2019	A Portrait of the Person Seen Through the Four Dimensions of Focusing	The Journal of Humanistic Counseling (The Journal of Humanistic Counseling)	58	3	233–248	Abstract In this article, the author examines how a person may be viewed through 4 dimensions of focusing: experiencing, reexperiencing, space, and the body. Elaborating on the theory and relevance to psychotherapy of each dimension, the author portrays a mindful, experiencing, sensing person who stands in the openness of not knowing; taps into the body as a resource to navigate life; creates new, fluid understandings of self and life; cocreates meaning with others; and lives forward with these novel meanings.
Indumathi, Mylanayakanah osahalli Chandrashekar; Swetha, Kamatam; Abhilasha,	2023	Selenium Ameliorates Acetaminophen-Induced Oxidative Stress via MAPK and	Biological trace element research				Overdose of acetaminophen (paracetamol), a widely used non-prescriptive analgesic and antipyretic medication, is one of the main causes of drug-induced acute liver failure around the world. Oxidative stress contributes to this hepatotoxicity. Antioxidants are known to protect the liver from oxidative stress. Selenium, a potent antioxidant, is a commonly used micronutrient.

<p>Kandahalli Venkatarangana yaka; Siddappa, Shiva; Kumar, Shivamadhaiah Manjula; Prasad, Govinda Keerthi; Chen, Chu-Huang; Marathe, Gopal Kedihithlu</p>		<p>Nrf2 Pathways in Mice</p>					<p>Here, we evaluated the protective effect of selenium on acetaminophen-induced hepatotoxicity. Treating Wistar albino mice with sodium selenite (1 mg/kg) before or after inducing hepatotoxicity with acetaminophen (150 mg/kg) significantly reduced the levels of liver injury biomarkers such as serum glutamate oxaloacetate transaminase and serum glutamate pyruvate transaminase. In addition, selenium-treated mice showed decreased levels of oxidative stress markers such as protein carbonyls and myeloperoxidase. Acetaminophen treatment stimulated all three mitogen-activated protein kinases (MAPKs) and Keap1 and decreased the expression of nuclear factor erythroid 2-related factor 2 (Nrf2) and heme oxygenase-1 in liver and in isolated mouse peritoneal macrophages, which was reversed by selenium treatment. Our findings suggest that the reactive oxygen species-mediated Nrf2 and MAPK pathways are critical players in acetaminophen-induced hepatotoxicity. These key findings offer an alternative therapeutic target for addressing acetaminophen-induced hepatotoxicity.</p>
<p>Isaac, Mathew S.</p>	<p>2023</p>	<p>The cure effect: Individuals demand universal access for health treatments that claim to eliminate disease symptoms</p>	<p>Journal of Experimental Psychology: Applied</p>	<p>29</p>	<p>3</p>	<p>544–556</p>	<p>The present research documents a cure effect, whereby individuals are more likely to demand affordable prices when health treatments (e.g., drugs, medications, therapies) claim to eliminate (vs. reduce) disease symptoms. This preference for low-priced “cures” contradicts the fundamental premise of value-based pricing, which would expect individuals to tolerate higher prices for cures because they are putatively more effective and therefore more valuable. Five studies with over 2,500 participants provide robust evidence for the cure effect and show that it occurs because individuals judge a health treatment’s acceptable price by focusing predominantly on its communal value rather than its</p>

							market value. Given that cures are associated with maximal effectiveness, they are disproportionately endowed with communal value and more likely to yield price judgments that reflect concerns about universal access. (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Isele, Gabriele	2020	Gendergerechte Sprache und Schreibweise - Problem und Herausforderung	Gesprchspsych otherapie und Personzentrierte Beratung	51	2	27	Reflektiert wird die Notwendigkeit, der Nutzen und mgliche Probleme des Verwendens einer mglichst gender-sensiblen Sprache und Schreibweise.

		Advanced Heart Failure					
IsHak, Waguih William; Korouri, Samuel; Darwish, Tarneem; Vanle, Brigitte; Dang, Jonathan; Edwards, Gabriel; Black, Jeanne T.; Aronow, Harriet; Kimchi, Asher; Spiegel, Brennan; Hedrick, Rebecca; Chernoff, Robert; Diniz, Marcio A.; Mirocha, James; Manoukian, Vicki; Harold, John; Ong, Michael K.; Wells, Kenneth; Hamilton, Michele; Danovitch, Itai	2021	Personalized treatments for depressive symptoms in patients with advanced heart failure: A pragmatic randomized controlled trial	PloS one	16	1	e0244453	<p>OBJECTIVES Heart Failure is a chronic syndrome affecting over 5.7 million in the US and 26 million adults worldwide with nearly 50% experiencing depressive symptoms. The objective of the study is to compare the effects of two evidence-based treatment options for adult patients with depression and advanced heart failure, on depressive symptom severity, physical and mental health related quality of life (HRQoL), heart-failure specific quality of life, caregiver burden, morbidity, and mortality at 3, 6 and 12-months.</p> <p>METHODS Trial design. Pragmatic, randomized, comparative effectiveness trial. Interventions. The treatment interventions are: (1) Behavioral Activation (BA), a patient-centered psychotherapy which emphasizes engagement in enjoyable and valued personalized activities as selected by the patient; or (2) Antidepressant Medication Management administered using the collaborative care model (MEDS). Participants. Adults aged 18 and over with advanced heart failure (defined as New York Heart Association (NYHA) Class II, III, and IV) and depression (defined as a score of 10 or above on the PHQ-9 and confirmed by the MINI International Neuropsychiatric Interview for the DSM-5) selected from all patients at Cedars-Sinai Medical Center who are admitted with heart failure and all patients presenting to the outpatient programs of the Smidt Heart Institute at Cedars-Sinai Medical Center. We plan to randomize 416 patients to BA or MEDS, with an estimated 28% loss to follow-up/inability to collect follow-up data. Thus, we plan to</p>

							<p>include 150 in each group for a total of 300 participants from which data after randomization will be collected and analyzed.</p> <p>CONCLUSIONS</p> <p>The current trial is the first to compare the impact of BA and MEDS on depressive symptoms, quality of life, caregiver burden, morbidity, and mortality in patients with depression and advanced heart failure. The trial will provide novel results that will be disseminated and implemented into a wide range of current practice settings.</p> <p>REGISTRATION</p> <p>ClinicalTrials.Gov Identifier: NCT03688100.</p>
Iwakabe, Shigeru; Conceicao, Nuno	2016	Metatherapeutic processing as a change-based therapeutic immediacy task: Building an initial process model using a task-analytic research strategy	Journal of Psychotherapy Integration	26	3	230-247	<p>The present study examined one particular class of therapeutic immediacy events called metatherapeutic processing in accelerated experiential dynamic psychotherapy (AEDP), in which a piece of successful therapeutic work just completed is reviewed and processed by both therapist and client. A task-analytic research strategy was used to analyze 4 clear and exemplary instances of metatherapeutic processing in videotaped sessions conducted by the developer of the approach. A process model was generated in which the therapist's interventions were represented at the level of change principles, and clients' change processes were represented along both affective and reflective tracks. Therapist interventions followed 4 principles of change: affirmation, attunement, somatic and experiential focusing, and restructuring. The affective track in the client change processes had 4 components: relief, enlivenment, grief, and peacefulness, while the reflective track had 3 components: self-affirmation, becoming aware of self-limiting beliefs and behavior, and engaging</p>

							in new emotional coping. Central to metatherapeutic processing events was the change process associated with tracking and processing the experience of positive emotions that organically emerged from successful work with painful emotional experiences. The implications of actively working with clients' spontaneously emergent positive emotional experiences during metatherapeutic processing will be addressed in relation to therapeutic immediacy, the broaden-and-build theory of positive emotions, and psychotherapy training and practice. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Iwakabe, Shigeru; Edlin, Jenn; Thoma, Nathan	2022	A phenomenological case study of accelerated experiential dynamic psychotherapy: The experience of change in the initial session from a client perspective	Journal of Psychotherapy Integration	32	4	363–376	We present a single case phenomenological study of a client's subjective experience of the initial session of accelerated experiential dynamic psychotherapy (AEDP; Fosha, 2021). It investigates the AEDP phenomenon of healing from the get-go, therapeutic experiences that can begin in the very first session, by examining an example in which the client felt particularly impacted by the very first session. The client was an adult male in his 40s experiencing emotional "deadness." The therapist was the originator of AEDP. The client was interviewed for 2 hr about his subjective experience in the initial session of therapy. The data were analyzed using the interpretative phenomenological approach. Eight themes were found in three domains. Three themes were found in the domain of the therapist and therapeutic relationship: extraordinary empathy, unequivocal affirmation, and profound connection. Two themes were found in the domain of significant in-session experiences: integrating the emotional self and welcoming change and accompanying positive emotions. Finally, three themes were found in the domain of general change: practicing emotional

							competence, deep transformation, and energy aliveness and positivity. Therapeutic relational conditions set a stage for the dyad to access the client's core issues or the source of suffering as well as his internal resources and strengths from the beginning of therapy and to produce positive emotions such as a sense of achievement in doing so. These themes will be discussed in relation to the in-session exchanges between the therapist and the client. (PsyInfo Database Record (c) 2022 APA, all rights reserved)
Iwakabe, Shigeru; Edlin, Jennifer; Fosha, Diana; Gretton, Heather; Joseph, Andrew J.; Nunnink, Sarah E.; Nakamura, Kaori; Thoma, Nathan C.	2020	The effectiveness of accelerated experiential dynamic psychotherapy (AEDP) in private practice settings: A transdiagnostic study conducted within the context of a practice-research network	Psychotherapy	57	4	548–561	Accelerated experiential dynamic psychotherapy (AEDP) is an integrative model of psychotherapy that brings together relational and experiential work, with the aim of not only alleviating suffering but also bringing about flourishing. The present study took place within a developing AEDP practice research network and examined outcomes for 62 self-referred adults treated using a 16-session format of AEDP treatment. Participants completed self-report measures before and following treatment. Measures assessed a variety of psychological problems, subjective distress, as well as aspects of positive psychological functioning. Treatment occurred in naturalistic independent practice outpatient settings in the United States, Canada, Israel, Japan, and Sweden. Large effect sizes ($d > 0.80$) were obtained for clinical problems and subjective distress. The majority of patients evidenced clinically reliable change according to Jacobson, Roberts, Berns, and McGlinchey's (1999) criteria. Effectiveness was further examined by dividing the sample into a clinical group with pervasive and severe problems and a subclinical group with fewer problems and mild severity. Within the clinical group, total and global scores on all measures improved significantly

						following treatment. Effect sizes were $d > 1.00$ for all scales. The subclinical group also demonstrated significant improvements, with effect sizes ranging from $d = 0.46$ to $d = 2.07$. These results provide initial empirical support for the effectiveness of AEDP as a model of therapy that can effect meaningful and significant improvements across a range of psychological symptoms. (PsycInfo Database Record (c) 2020 APA, all rights reserved)
Iwakabe, Shigeru; Edlin, Jennifer; Fosha, Diana; Thoma, Nathan C.; Gretton, Heather; Joseph, Andrew J.; Nakamura, Kaori		The long-term outcome of accelerated experiential dynamic psychotherapy: 6- and 12-month follow-up results	Psychotherapy	59	3	Accelerated experiential dynamic psychotherapy (AEDP; Fosha, 2000, 2021b) is an integrative, healing-oriented, mind-body, affect-focused therapy. A posttreatment outcome study demonstrated AEDP's effectiveness (Iwakabe et al., 2020) on a variety of measures of psychological functioning. This study sought to address AEDP's long-term effectiveness. As previously reported, 63 adult patients completed a 16-session AEDP treatment with qualified therapists in private practice in the United States, Canada, Israel, Japan, and Sweden. Forty patients responded to 6-month follow-up and 52 responded to 12-month follow-up. Results indicate that patients maintained their posttreatment therapeutic gains, both 6 and 12 months later. Large effect sizes ($d = 0.74$ to $d = 1.60$) both for reductions on measures of psychopathology (e.g., depression, negative automatic thoughts, experiential avoidance) and improvements on measures of positive mental health (e.g., well-being, self-compassion) were obtained. Patients with more pervasive and severe problems tended to have larger effect sizes (all $ds > 1.0$) and a larger proportion of them achieved clinically significant change over 6 and 12 months than patients with subclinical symptomatology. Piecewise growth modeling was used to confirm these results, with

							attrition over the follow-up period taken into account. Consistent with the above findings, piecewise growth modeling similarly showed that patients significantly improved from pre- to posttreatment and maintained gains from posttreatment through the 6- and 12-month follow-up. These results provide empirical support for the long-term effectiveness of AEDP for alleviating a variety of psychological problems and enhancing positive functioning. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Iwakabe, Shigeru; Nakamura, Kaori; Thoma, Nathan C.	2023	Enhancing emotion regulation	Psychotherapy research : journal of the Society for Psychotherapy Research	33	7	918–945	Background: Emotion regulation (ER) refers to the process of modulating an affective experience or response. Objectives: This is a systematic review of the research on therapist methods to facilitate patient ER, including affect-focused, experiential methods that aim to enhance immediate patient emotion regulation, and structured psychoeducation, skills training in ER. Method: A total of 10 studies of immediate and intermediate outcomes of emotion regulation methods were examined. A total of 38 studies were included in the meta-analysis of distal treatment effects on emotion regulation. Results: In eight studies with 84 clients and 33 therapists, we found evidence of positive intermediate outcomes for affect-focused therapist methods and interpretations. A meta-analysis of 26 studies showed that the average effect size of ER methods from pre- to post-treatment was large ($g = 0.82$). Conclusions: Both affect-focused and structured skill training are associated with distal improvements in emotion regulation. When working with ER in psychotherapy, therapists must consider how patients' cultural backgrounds inform display rules, as well as what might be considered adaptive or maladaptive. The article

							concludes with training implications and therapeutic practices based on the research evidence.
Jacob, Gitta	2021	Auf der Gefühlsebene. Emotionsfokussierte Techniken effektiv und zielorientiert einsetzen					Der effektive und zielorientierte Einsatz emotionsfokussierter Techniken in der Psychotherapie wird beschrieben. Mittels einer Heuristik und anhand von Fallbeispielen wird vorgestellt, in welchen Situationen und mit welchen Zielen emotionsfokussierende Interventionen gut in die Sitzung eingebettet, durchgeführt und abgeschlossen werden können. Werden emotionsfokussierte Methoden richtig eingesetzt, helfen sie Patientinnen und Patienten, Emotionen zu erleben, die sie zuvor vermieden oder unterdrückt haben. So können Emotionen endlich ihre adaptive Funktion erfüllen - die Aufmerksamkeit auf grundlegende Bedürfnisse lenken und darauf, was bedeutsam ist. - Inhalt: (A) Einführung in die Arbeit mit emotionsfokussierten Techniken. (1) Was sind emotionsfokussierte Techniken? (2) Der Gegenstand emotionsfokussierter Techniken: Konflikte und Widerstand. (3) Was wird mit emotionsfokussierten Techniken angestrebt? (4) Steuerung emotionaler Prozesse. - (B) Emotionsfokussierte Techniken anwenden. (5) Der therapeutische Entscheidungsbaum. (6) Was will die Patientin, was sie nicht hat? (7) Ist das, was die Patientin will, realistisch erreichbar? (8) Wenn die Patientin unerreichbare Ziele verfolgt: Können Sie als Therapeutin damit klar, dass sie das nicht erreichen kann? (9) Wenn die Patientin erreichbare Ziele verfolgt: Warum erreicht sie sie nicht? (10) Wenn die Patientin unerreichbare Ziele verfolgt: Warum verfolgt sie sie trotzdem?

Jahn, Judith	2017	Partnerschaftliches Focusing als Selbsthilfemethode zur Bewältigung chronischer körperlicher Krankheit	Person	21	2	98–109	In einer qualitativen Studie wurde der Frage nachgegangen, ob die von E. T. Gendlin entwickelte Selbsthilfemethode "Partnerschaftliches Focusing" Menschen bei der Bewältigung einer chronischen körperlichen Krankheit unterstützt. Ferner wurde untersucht, auf welche Weise Effekte zustande kommen. Es wurden acht chronisch körperlich kranke Menschen, die regelmäßig partnerschaftlich fokussieren, entsprechend dem narrativen Interview von F. Schtze befragt. Im Ergebnis zeigten sich Anzeichen von Krankheitsbewältigung in Form von Stressreduktion, veränderter subjektiver Wahrnehmung der chronischen körperlichen Krankheit sowie Besserung oder Heilung von chronischen körperlichen Krankheitssymptomen. Dabei spielten das Erleben von Eigenständigkeit und Selbstbestimmung im Focusing-Prozess sowie die individuelle Nutzungsstrategie eine wesentliche Rolle. Eine datenbegründete Theorie zur Nutzung des Partnerschaftlichen Focusing wird zur Diskussion gestellt.
Jankowski, Peter J.; Captari, Laura E.; Sandage, Steven J.	2021	Exploring virtue ethics in psychodynamic psychotherapy: latent changes in humility, affect regulation, symptoms and well-being	Couns and Psychother Res (Counselling and Psychotherapy Research)	21	4	983–991	

Jankowski, Peter J.; Sandage, Steven J.; Bell, Chance A.; Rupert, David; Bronstein, Miriam; Stavros, George S.	2019	Latent trajectories of change for clients at a psychodynamic training clinic	Journal of clinical psychology	75	7	1147–1168	OBJECTIVE: Employing practice-based research methods, we addressed the need to examine the effectiveness of psychodynamic treatment as a supplement to the efficacy evidence offered by randomized clinical trials. METHOD: We used person-centered analyses to generate latent subgroups of clients (N = 118; M (age) = 40.92; 53.4% female; 81.4% Caucasian; 80.5% heterosexual) receiving contemporary relational psychotherapy (CRP) at a psychodynamic community mental health training clinic. RESULTS: Subgroups of clients reported a change in depression, social conflict, and anxiety symptomatology, and overall life satisfaction, depicted by significant quadratic growth curves. Findings also offered exploratory support for a theoretical proposition from CRP that improved relational functioning would correspond to improved affect dysregulation and overall life satisfaction. CONCLUSION: Clinical and training implications highlight the need to distinguish subgroups of "responders" and "nonresponders" to inform treatment.

Jauk, Emanuel; Blum, Charlotte; Hildebrandt, Malin; Lehmann, Konrad; Maliske, Lara; Kanske, Philipp	2023	Psychological and neural correlates of social affect and cognition in narcissism: A multimethod study of self-reported traits, experiential states, and behavioral and brain indicators	Personality Disorders: Theory, Research, and Treatment		19-27(23)	No Paginat n Specified -No Paginat n Specified	“Lack of empathy” is a diagnostic criterion of narcissism, but the nature of interpersonal functioning in narcissism is still being debated. Both, empathy and narcissism, are multidimensional constructs, and their relation might depend upon contextual factors. We investigated social affect and cognition in narcissism spanning self-reported traits and experiential states (Ecological Momentary Assessment) as well as behavioral and brain indicators (task-related functional magnetic resonance imaging). N = 140 individuals were selected to cover the full dimensional range of grandiose and vulnerable narcissism, including their constituent self-regulatory dimensions of agentic, antagonistic, and neurotic narcissism. Grandiose narcissism was associated with lower social affect at almost all analysis levels. The associations can be attributed to antagonistic self-regulatory dynamics, and are associated with lower brain activation during subjective experiencing of social affect in regions of the salience network. Social cognition was habitually lowered but not impaired in antagonistic narcissism. Our findings do not support a general “lack of empathy.” (PsycInfo Database Record (c) 2023 APA, all rights reserved)
Jeanpierre, Pauline; Parant, Aymeric;	2023	Animal mediation and social bond: a	Geriatric et psychologie neuropsychiatri	21	3	384–394	Ehpad are French establishments intended to elderly people in a situation of physical and/or psychological loss of autonomy. Institutionalization in Ehpad is often synonymous with the disruption of social ties. In this

Laguetto, Vanessa		psychosocial study in Ehpad	e du vieillissement				<p>context, different group activities are likely to favour the residents' relationships. Among these activities, animal mediation is an emerging approach that is gradually being introduced in these establishments. The aim of this research is to study the benefits of animal mediation on the social bond of Ehpad residents, according to animal mediation practitioners and professionals working in these establishments. Semi-directive interviews were carried out with nine professionals working in Ehpad in daily contact with the residents and who had attended collective sessions. These professionals were invited to give their views on the interactions between residents and on the benefits of the sessions. At the same time, fifty animal mediation practitioners responded to a questionnaire aimed at determining the place given to the development of social links in their practices. The professionals working in Ehpad described animal mediation as a practice that facilitates interactions during the sessions but also outside. For residents for whom verbalization is difficult or even impossible, animal mediation is presented as facilitating non-verbal communication. These comments converge with the discourse of animal mediation practitioners who place the creation of social links and the development of social skills at the heart of their practices. They highlight the central role of the animal which facilitates interactions and provides an emotional exchange.</p>
Jecht, Gudrun; Kauka, Elke	2017	Spielerisch arbeiten. Transaktionsana lytische Therapie mit					<p>Die transaktionsanalytische Therapie mit Kindern und Jugendlichen wird beschrieben. An Fallbeispielen werden transaktionsanalytische Arbeitsweisen bei der Diagnostik und Behandlung veranschaulicht. Dabei werden unterschiedliche methodische Anstze, persnliche therapeutische Stile und Herangehensweisen sichtbar.</p>

Jeffrey, Christina E.; Ridley, Charles R.	2017	A Case Conceptualization Using Thematic Mapping	Journal of clinical psychology	73	4	410–424	This article, the last in a series of 5, presents a detailed case summary in which thematic mapping, a novel method of case conceptualization, was used to conceptualize an adult struggling with chronic depression. The case illustrates the process and therapeutic outcomes that resulted from the therapist's use of the 3-stage thematic mapping model: theme identification, theme interpretation, and theme intervention. The article also demonstrates how the case formulation guided the therapist in selecting therapeutic techniques that matched to the client's goals, needs, and interpersonal style. Overall, this article aims to demonstrate how thematic mapping utilizes transtheoretical and transdiagnostic approaches to create a case formulation that is client-centered, process-oriented, and useful across a broad spectrum of training.
Jenks, Amanda; Adams, Gwen; Young, Bonnie; Seedall, Ryan	2023	Addressing power in couples therapy: Integrating socio-emotional relationship therapy and emotionally focused therapy	Family process				Romantic relationships are more satisfying and fulfilling when power is balanced relatively equally between partners (Leonhardt et al., Journal of Family Psychology, 34, 2020, and 1). Yet, few couples therapy models explicitly outline how to confront relational power issues (Knudson-Martin & Huenergardt, 2015, Socio-emotional relationship therapy: Bridging emotion, societal context, and couple interaction, Springer). Emotionally Focused Therapy (EFT; Johnson, 2020, The practice of emotionally focused couple therapy, Routledge) is a well-established, evidence-based therapy modality that many therapists use with couple clients, yet despite its effectiveness, it

							does not provide direction for explicitly addressing and treating power differentials in couple relationships. In this paper, we explore the integration of EFT with Socio-emotional Relationship Therapy (SERT), a model overlay that acknowledges the impact of social discourse on enactments of power in intimate couple relationships. We first address the importance of understanding power in couple relationships, addressing power in couples therapy, and provide a brief overview of SERT and EFT. We then introduce an integration of the models intended to help therapists balance power, increase connection, and secure attachment bonds between romantic partners.
Jensen, Katherine C.; Rostosky, Sharon S.	2021	Sexual assault survivors' experiences and perceptions of equine facilitated therapeutic activities	Practice Innovations	6	4	251-262	Current literature suggests equine-facilitated psychotherapy (EFP) may be an effective intervention in reducing trauma-related symptoms. Little is known, however, about clients' perceptions of the benefits of working with a horse as a dynamic member of the therapeutic team. We gathered focus group data for the purpose of systematically exploring the perceived benefits experienced by 12 women who participated in the Equine Assisted Survivors of Trauma (EAST) group for sexual assault survivors. Findings from a thematic analysis of data (Braun & Clarke, 2006) indicated that participants experienced the equine therapeutic environment as restorative. They also described benefits of working with the horses that included positive emotional experiences, increased insight and awareness, and improved relationship skills. These findings suggest specific elements of EFP that may be particularly useful and impactful for trauma survivors and deserving of further research. Jericho, Brooke; Luo, Aileen; Berle, David	2022	Trauma-focused psychotherapies for post-traumatic stress disorder: A systematic review and network meta-analysis	Acta psychiatrica Scandinavica	145	2	132-155	<p>INTRODUCTION Meta-analytic reviews suggest similar outcomes across trauma-focused psychotherapies for adults with post-traumatic stress disorder (PTSD). However, this conclusion may be premature due to suboptimal statistical-review methodologies. Network meta-analysis (NMA) allows a detailed rank-ordering of the efficacy of established psychotherapy interventions derived from indirect evidence as well as results from direct head-to-head comparisons.</p> <p>OBJECTIVE We sought to determine the efficacy and attrition rates of psychotherapy interventions for PTSD by applying NMA.</p> <p>METHODS We searched EMBASE, PsychINFO, PTSDPubs and PubMed for randomised controlled trials that compared psychotherapies either head-to-head or against controls for adults with PTSD. A frequentist NMA was used to compare direct and indirect effects to determine the efficacy and attrition rates of psychotherapy interventions.</p> <p>RESULTS Of the 5649 papers identified, 82 trials comprising of 5838 patients were included. The network comprised 17 psychotherapies and four control conditions. Network estimates indicated superior efficacy of meta-cognitive therapy and cognitive processing therapy over other psychotherapies (ESs between = 0.26 and 2.32). Written exposure therapy and narrative exposure therapy were associated with lower risk of drop out when considered alongside other psychotherapies. Confidence in the network meta-analytic estimates was considered moderate for both outcomes.</p>
--	------	--	--------------------------------------	-----	---	---------	---

							<p>CONCLUSIONS</p> <p>In broad terms, therapeutic commensurability was evident. Nevertheless, with additional studies and larger sample sizes, meta-cognitive and written exposure therapies could indeed differentiate themselves from other approaches as having favourable efficacy and acceptability respectively. These findings may inform clinical decision-making, as well as guide future research for PTSD.</p>
Jessell, Lauren; Stanhope, Victoria	2022	“How do you try to have anyone comply or at least be pliable with you if that person’s not even medicated?”: Perspectives on the use of psychiatric medication within recovery-oriented practice	Psychiatric Rehabilitation Journal		15 59- 31 26(Ele ctr oni c), 10 95- 15 8X(Pri nt)	153-159	<p>Objective: Medication is particularly important to advocates within the mental health recovery movement and this movement is founded upon a resistance to coercive treatment. Given this history, we explored the perspectives of providers and service users engaged in the recovery-oriented practice Person-Centered Care Planning (PCCP) to understand (a). How providers trained in PCCP understand the role of psychiatric medication and (b). How service users receiving services from providers trained in PCCP understand and experience the role of psychiatric medication in treatment. Method: This study comprises data from the qualitative phase of an NIMH-funded randomized trial of PCCP, an evidence-based recovery-oriented practice. Data were collected from 22 focus groups of providers and service users across seven community mental health centers. Interviews were analyzed using thematic analysis. Results: Qualitative themes from the provider focus groups included “promoting adherence” and “medication as a precondition.” Providers expressed that service users need to be adherent to medication and their symptoms managed before recovery-oriented practices could be pursued. Service user themes included “we were cattle” and medication as “my saving grace.” While many</p>

							experienced medication as helpful, they found providers' focus on adherence to be inflexible and, at times, coercive. Conclusion and Implications for Practice: These results suggest that even within agencies actively implementing recovery-oriented practices, there are aspects of treatment, namely medication management, that are more impervious to recovery principles. Agency level trainings in PCCP and other recovery-oriented practices would benefit from the inclusion of all staff, including psychiatrists and other prescribers. Jiang, Jiangling; Zhang, Caidi; Li, Chunbo; Chen, Zhimin; Cao, Xinyi; Wang, Hongyan; Li, Wei; Wang, Jijun	2021	Magnetic seizure therapy for treatment-resistant depression	The Cochrane database of systematic reviews	6	6	CD013528	<p>BACKGROUND Magnetic seizure therapy (MST) is a potential alternative to electroconvulsive therapy (ECT). Reports to date on use of MST for patients with treatment-resistant depression (TRD) are limited.</p> <p>OBJECTIVES To evaluate the effects of MST in comparison with sham-MST, antidepressant, and other forms of electric or magnetic treatment for adults with TRD.</p> <p>SEARCH METHODS In March 2020, we searched a wide range of international electronic sources for published, unpublished, and ongoing studies. We handsearched the reference lists of all included studies and relevant systematic reviews and conference proceedings of the Annual Meeting of the American College of Neuropsychopharmacology (ACNP), the Annual Scientific Convention and Meeting, and the Annual Meeting of the European College of Neuropsychopharmacology (ECNP) to identify additional studies.</p> <p>SELECTION CRITERIA All randomised clinical trials (RCTs) focused on MST for</p>

						<p>adults with TRD.</p> <p>DATA COLLECTION AND ANALYSIS</p> <p>Two review authors extracted data independently. For binary outcomes, we calculated risk ratios (RRs) and 95% confidence intervals (CIs). For continuous data, we estimated mean differences (MDs) between groups and 95% CIs. We employed a random-effects model for analyses. We assessed risk of bias for included studies and created a 'Summary of findings' table using the GRADE approach. Our main outcomes of interest were symptom severity, cognitive function, suicide, quality of life, social functioning, dropout for any reason, serious adverse events, and adverse events that led to discontinuation of treatment.</p> <p>MAIN RESULTS</p> <p>We included three studies (65 participants) comparing MST with ECT. Two studies reported depressive symptoms with the Hamilton Rating Scale for Depression (HAM-D). However, in one study, the data were skewed and there was an imbalance in baseline characteristics. Analysis of these two studies showed no clear differences in depressive symptoms between treatment groups (MD 0.71, 95% CI -2.23 to 3.65; 2 studies, 40 participants; very low-certainty evidence). Two studies investigated multiple domains of cognitive function. However most of the outcomes were not measured by validated neuropsychological tests, and many of the data suffered from unbalanced baseline and skewed distribution. Analysis of immediate memory performance measured by the Wechsler Memory Scale showed no clear differences between treatment groups (MD 0.40, 95% CI -4.16 to 4.96; 1 study, 20 participants; very low-certainty evidence). Analysis of delayed memory performance</p>
--	--	--	--	--	--	---

						<p>measured by the Wechsler Memory Scale also showed no clear differences between treatment groups (MD 2.57, 95% CI -2.39 to 7.53; 1 study, 20 participants; very low-certainty evidence). Only one study reported quality of life, but the data were skewed and baseline data were unbalanced across groups. Analysis of quality of life showed no clear differences between treatment groups (MD 14.86, 95% CI -42.26 to 71.98; 1 study, 20 participants; very low-certainty evidence). Only one study reported dropout and adverse events that led to discontinuation of treatment. Analysis of reported data showed no clear differences between treatment groups for this outcome (RR 1.38, 95% CI 0.28 to 6.91; 1 study, 25 participants; very low-certainty evidence). Adverse events occurred in only two participants who received ECT (worsening of preexisting coronary heart disease and a cognitive adverse effect). None of the included studies reported outcomes on suicide and social functioning. No RCTs comparing MST with other treatments were identified.</p> <p>AUTHORS' CONCLUSIONS</p> <p>Evidence regarding effects of MST on patients with TRD is currently insufficient. Our analyses of available data did not reveal clearly different effects between MST and ECT. We are uncertain about these findings because of risk of bias and imprecision of estimates. Large, long, well-designed, and well-reported trials are needed to further examine the effects of MST.</p>	
Jofen-Miller, Sarah; Fiori, Katherine L.	2017	The impact of psychotherapist training and experience on	Psychotherapy	54	1	114-122	<p>This study sought to enhance our understanding of posttermination contact, with a particular focus on the role of training and experience in shaping attitudes and behaviors with respect to the posttermination period. We collected anonymous online survey data related to</p>

		posttermination contact					attitudes, policies, and experience of posttermination contact from 144 licensed clinicians. Our sample was composed of an experienced group of clinicians, with 20.7 years in practice on average. Clinicians had a range of clinical orientations and ~25% of respondents were from outside of the United States. Over 90% of the participants (130) endorsed having had some form of posttermination contact, and 25% (36) reported initiating posttermination contact with a past patient. Only 62 participants (43.4%) reported receiving graduate training related to posttermination contact, and those with graduate training were more likely to have an established posttermination policy that they reviewed with patients. In addition, recent graduates were more likely to report having had training on this topic than older graduates. In terms of attitudes, therapists were more likely to anticipate positive rather than negative consequences of posttermination contact for both patients and themselves, and the longer a therapist had been in practice the less likely they were to anticipate negative consequences of posttermination contact. Additionally, a clinician's contact with their own therapist made them more likely to anticipate positive consequences for both themselves and their patients. Given the ubiquity of posttermination contact, the posttermination period should be given more attention in training programs and research. Jofer, Steffi	2021	"Weit du, Corona ist ein Riesenarschloch": Wenn Kinder	Gesprchpsych otherapie und Personzentrierte Beratung	52	4	12-15	Seit Dezember 2019 leben wir mit dem Virus SARS-CoV-2. Laut WHO befinden wir uns seit dem 30. Januar 2020 in einer internationalen Gesundheitsnotlage. Am 11. Mrz 2020 wurde die Pandemie ausgerufen. Die Kinder, die in meine spieltherapeutische Praxis kommen, haben neue

		"Pandemie spielen"					Begrifflichkeiten in ihren Wortschatz übernommen. Die 5-Jährigen sprechen vom Lockdown, vom Shutdown, kennen die verschiedenen Formen der Mund-Nase-Masken und wissen, dass ein Biergarten auch eine Außengastronomie ist. Die Fachsprache der Pandemie aus der Erwachsenenwelt hat sich in die Sprache der Kinder eingefügt. Dieser Text beschäftigt sich mit der Frage, ob sich die gesellschaftlichen Phänomene, welche durch die Covid-19-Pandemie entstanden sind, in der Kinderwelt und damit in der Sprache des Kindes, dem Spiel, abbilden.
Jofer-Ernstberger, Steffi	2023	Die Bedeutung der Babyflasche: Sinnliches Nach- und Selbstnähren in der Personzentrierten Kindertherapie	Gesprächspsychotherapie und Personzentrierte Beratung	54	1	25–31	Die Baby- bzw. Nuckelflasche geht für die Pionierinnen und Pioniere der Personzentrierten Kindertherapie zur Grundausstattung eines Spielzimmers (Axline1, 1947/1972, S. 56; Behr, 2012, S. 112; Goetze2, 2002, S. 152; Hockel, 2004; Tausch & Tausch, 1956, S. 29; Weinberger, 2015, S. 131). In meiner Praxis steht sie - gemeinsam mit verschiedenen Schnullern - in der Kochecke, neben einem Kindersofa, und ergänzt durch das Bilderbuch "Wer weiß, was unser Baby will" (Root & Barton, 1999). Die Babyflasche dient im Spielzimmer kaum dem Zweck, die jungen Gäste satt zu bekommen bzw. ihren Durst zu stillen - begleite ich doch Kinder, die in der Regel mindestens vier Jahre alt sind und schon die Fähigkeit besitzen aus einem Glas zu trinken. Folge ich dem Hinweis von Goetze (2002, S. 21), dass Spielmittel im Spielzimmer die Funktion von Wörtern einnehmen, stellt sich die Frage, welche symbolischen Mitteilungen ich "höre" und was im Nuckeln mit der Babyflasche verstanden werden soll. Diesem Verstehensversuch widme ich mich im folgenden Artikel und richte meinen Blick auf die Bedeutung des Saugens und Nuckelns aus unterschiedlichen Perspektiven.

Johannsen, Maja; Schlander, Christina; Farver-Vestergaard, Ingeborg; Lundorff, Marie; Wellnitz, Kaare Bro; Komischke-Konnerup, Katrine B.; O'Connor, Maja	2022	Group-based compassion-focused therapy for prolonged grief symptoms in adults - Results from a randomized controlled trial	Psychiatry research	314		114683	Prolonged grief disorder is a debilitating condition, which affects approximately one out of ten who lose a loved one. While existing meta-analyses have synthesized evidence regarding the overall effect of psychological interventions for pathological grief across different types of psychotherapy, it remains clinically relevant to explore whether specific types of psychological interventions are efficacious in the treatment of grief. The present study investigated the efficacy of group-based Compassion-Focused Therapy (CFT) for adults who had lost a spouse or a parent, and who reported clinically relevant levels of prolonged grief symptoms (PGS) at 11 months post-loss. A total of 82 participants were randomized to the CFT group (n = 42) or the waitlist control (n = 40). Time × group interactions showed no statistically significant effects of the intervention on the primary outcome PGS at post-intervention or 6-month follow-up. Likewise, no statistically significant effects were found for any of the secondary outcomes or process variables, with the exception of posttraumatic stress symptoms and self-reassurance. Taken together, in the present study group-based CFT did not emerge as an efficacious treatment for PGS. Possible explanations include that CFT may not target core maintaining processes in PGS and that the group-based, 8-week operationalization of CFT may be less than optimal.
Johnson, Austin H.; Yu, Rondy; Bains, Bhawandeep K.; Alba, Laura A.; Womack, Tyler A.	2023	Understanding preferences of general educators for supporting classwide behavior	School Psychology	38	2	100–109	Innovations, such as novel evidence-based practices, are not likely to diffuse to practice without explicit effort and design (Rogers, 2003). In an effort to understand how interventions should be designed to meet teacher preferences, the present study utilized a full-profile two-alternative forced-choice experiment to examine teacher preferences when selecting a classwide intervention to

							address student disruptive behavior. Attributes and levels for the experiment were derived in response to four characteristics from Rogers' diffusion of innovations theory. Results from 266 general education teachers of Grades K-5 indicated that nearly all theorized characteristics influenced teacher preference, with the exception of the observability of the intervention (i.e., receiving feedback from others). Specific findings of levels within attributes suggest that, for instance, short online video trainings are preferable to full-day workshops and specific details on adaptations for inclusivity are highly preferred. Given school psychologists' roles in consultation and behavior support, knowledge of teacher preferences may be utilized to support intervention uptake and more general dissemination efforts. Johnson, Christine C.; Loeffler, Bryan J.; Gaston, R. Glenn	2021	Targeted Muscle Reinnervation: A Paradigm Shift for Neuroma Management and Improved Prosthesis Control in Major Limb Amputees	The Journal of the American Academy of Orthopaedic Surgeons	29	7	288-296	Targeted muscle reinnervation (TMR) is a procedure that redirects nerves severed by amputation to new muscle targets. In tandem with advances in myoelectric prosthetics, TMR surgery provides amputees with improved control of myoelectric prostheses and simultaneously prevents or treats painful neuromas. TMR also has an emerging role in the management of neuromas in a nonamputation setting, and it seems to be a powerful strategy to treat a wide variety of neuromas. Because the pattern of nerve transfers varies based on the availability of donor nerves and muscle targets, TMR is inherently nonprescriptive, and thus, an understanding of the principles of TMR is essential for its successful application. This review describes the rationale for and principles of TMR, and outlines techniques for TMR, which can be used at various amputation levels and for the management of neuromas in nonamputees.

Johnson, E.; Bwititi, P. B.; Nwose, E. U.	2020	Barriers to management of diabetes foot ulcer: Experiential note from a setting with free medical services	Foot (Edinburgh, Scotland)	44		101658	The imperative need for behavioral agreement to overcome barriers of self-management of diabetes foot complication was recently articulated. A few journals have done parallel publications, which thereby stresses the significance of the issue. This article is to add to the "Overcoming barriers to self-management: the person-centred diabetes foot behavioural agreement". It presents experiential note with four tabulated cases of clients who have access to free state-of-the-art medical service; and non-adherence as a barrier to self-management is not due to affordances. It is to draw attention to the deliberately non-adherent patients where behavioral agreement process should be really driven by the client as in the real context of person-centered therapy.
Johnson, Emily M.; Possemato, Kyle	2021	Problem recognition and treatment beliefs relate to mental health utilization among veteran primary care patients		18	1		Mental health concerns are prevalent among primary care patients, but many do not utilize services for these conditions. This study aims to conduct a comprehensive assessment of barriers and facilitators to mental health care utilization among veteran primary care patients with common mental health concerns. We hypothesized that beliefs and knowledge about mental illness and mental health care would be more strongly associated with recent mental health care utilization than stigma, help-seeking behaviors, or logistical barriers. Veterans (n = 116) enrolled in primary care with current symptoms of depression (58%), posttraumatic stress disorder (37%), and/or hazardous alcohol use (50%) who either recently used mental health services (47%) or had no recent mental health treatment utilization (53%) completed a telephone-based screening, medical records review, and mail survey of 10 measures of barriers and facilitators to mental health treatment utilization. Recognition of problems as a cause for concern, odds ratio = 5.95, 95%

							confidence interval [2.36, 15.01], and beliefs about psychotherapy, odds ratio = 2.53, 95% confidence interval [1.39, 4.60], emerged as stronger correlates of recent mental health care utilization than stigma, self-efficacy, and external barriers to treatment. Results suggest the use of specific theories, measures, and interventions that focus on patient recognition of problems and beliefs about treatment over those that focus on other treatment barriers and facilitators. (PsycInfo Database Record (c) 2021 APA, all rights reserved)
Johnson, Shannon K.; Sternberg, Kirk von; Velasquez, Mary M.	2017	A Comparison of Profiles of Transtheoretical Model Constructs of Change among Depressed and Nondepressed Women at Risk for an Alcohol-Exposed Pregnancy	Women's health issues : official publication of the Jacobs Institute of Women's Health	27	1	100-107	INTRODUCTION: The efficacy of a series of interventions to reduce risk of alcohol-exposed pregnancies is well-established, yet some subsets of women remain at risk. For instance, in CHOICES, a randomized clinical trial of an intervention to prevent alcohol-exposed pregnancy, nondepressed women reduced risk drinking at roughly twice the rate of women with depression (49% vs. 24%). This secondary analysis of CHOICES data examines constructs that can explicate differences between nondepressed and depressed women in the process of changing alcohol behavior. METHODS: Profile analysis was used to compare the current status on transtheoretical model constructs of change between groups of depressed (n = 41) and nondepressed (n = 171) women in CHOICES at baseline and at the 9-month follow-up (end of the study). Participants were women aged 18 to 44 years who were at risk for an alcohol-exposed pregnancy at baseline. Measures included the Timeline Followback, Brief Symptom Inventory, and the transtheoretical model measures of decisional balance, self-efficacy, and experiential and behavioral processes of change. RESULTS: Differences in profiles of the transtheoretical model constructs between groups were

						found at baseline and 9 months ($p < .001$). Women with depression had a profile that has historically predicted failure to change. Profiles among depressed women were distinguished by high scores on cons for changing alcohol use and temptation to drink. CONCLUSIONS: Prevention interventions should assess for depression and target interventions to improve success. Results of this study can help practitioners to better tailor interventions to the needs of individuals with depression by strategically targeting decisional balance and self-efficacy.
Johnson, Sue	2020	Bindungstheorie in der Praxis. Emotionsfokussierte Therapie mit Einzelnen, Paaren und Familien				Die praktische Anwendung der Bindungstheorie in der Emotionsfokussierten Therapie mit Einzelnen, Paaren und Familien wird erlutert. Das grundlegende Bedrfnis in zwischenmenschlichen Beziehungen ist die sichere emotionale Verbindung. Es verwundert daher nicht, dass Bowlbys Bindungstheorie und die Emotionsfokussierte Therapie (EFT) sich schon lange gegenseitig befruchten, um das soziale Gefge von Klienten zu frdern. Beide Konzepte werden hier erstmals explizit als sich ergnzende Anstze vorgestellt. Die integrierte Umsetzung in verschiedenen Settings wird zudem anhand von Beispielen veranschaulicht. Indem die Resultate der Bindungsforschung in die EFT einbezogen werden, knnen Praktizierende besser verstehen, was in Menschen und ihren Beziehungen tatschlich geschieht - und somit ihren Klienten zielgenauer helfen. - Inhalt: (1) Bindung: ein unentbehrlicher Leitfaden fr eine wissenschaftsgesttzte Praxis. (2) Bindungstheorie und -wissenschaft als Modell therapeutischer Vernderung. (3) Intervention: mit Emotionen arbeiten, um korrigierende Erfahrungen und Interaktionen zu konstruieren. (4) Emotionsfokussierte Einzeltherapie im Bindungsrahmen: Erweiterung des Selbstgefhlts. (5) Emotionsfokussierte Einzeltherapie in

							der Praxis. (6) In der Emotionsfokussierten Paartherapie heilen und gesund werden. (7) Emotionsfokussierte Paartherapie in der Praxis. (8) Wiederherstellung der Familienbande in der Emotionsfokussierten Familientherapie. (9) Emotionsfokussierte Familientherapie in der Praxis. (10) Postskript: das Versprechen der Bindungswissenschaft. (11) Anhang (Bindung messen; allgemeine Faktoren und Prinzipien der Therapie; Emotionsfokussierte Einzeltherapie und andere empirisch getestete Verfahren, die mit der Bindungsperspektive arbeiten).
Johnson, Sue M.	2021	Praxis der Emotionsfokussierten Paartherapie. Verbindungen herstellen					Die Praxis der emotionsfokussierten Paartherapie wird beschrieben. In die dritte, bearbeitete Auflage wurden aktuelle Entwicklungen in der Paartherapie einbezogen und neuere Forschungsergebnisse zu klinischen Interventionen aufgenommen. Berücksichtigt wurden außerdem ein erweitertes Verständnis von Emotionsregulation, Erkenntnisse aus den Neurowissenschaften und zum Bindungsverhalten Erwachsener sowie dynamische Anwendungen emotionsfokussierter Therapie für Probleme wie Depressionen, Angstzustände, sexuelle Störungen und posttraumatische Belastungsstörungen. Als einer der plausibelsten, am besten dokumentierten und erforschten paartherapeutischen Ansätze ist die Emotionsfokussierte Paartherapie (EFPT) eine der wirksamsten Beziehungstherapien. Das Buch bietet einen Werkzeugkasten von Interventionen und einen Leitfaden für den Prozess der Veränderung. - Inhalt: https://d-nb.info/1222293544/04

Leanne; Campisi, Claudia		Einzeltherapie (EFIT)					
Johnson, Susan	2019	Attachment in action-changing the face of 21st century couple therapy	Current opinion in psychology	25		101-104	The field of couple therapy-one of the most widely sought and practiced modality of therapy-has been revolutionized by the emergence of attachment science in the 21st century. We now understand not only the centrality of close relationships for human health and wellbeing, but also that the key to a healthy happy relationship is a secure attachment bond. Emotionally Focused Therapy is an attachment-based approach that aims to help couples create a secure attachment bond. Several outcome studies have shown that EFT helps to not only alleviate relationship distress but individual co-morbidities as well, with positive follow-up effects. EFT appears to help couples not only improve their relationships but also access the optimal resilience and wellbeing secure attachment allows. Copyright 2018 Elsevier Ltd. All rights reserved.

						<p>additional information as required. We analysed continuous data using mean difference (MD) for outcomes using a single measure, and standardised mean difference (SMD) for outcomes using multiple measures, and risk ratios (RR) for dichotomous data. All data are presented with 95% confidence intervals (CIs). We undertook meta-analyses using random-effects models.</p> <p>MAIN RESULTS</p> <p>We included evidence from 1925 participants in 15 RCTs that investigated the effect of 17 interventions. All included studies were published after 2005. Interventions included seven parenting interventions, eight psychological interventions and two service system approaches. The studies were funded by major research councils, government departments and philanthropic/charitable organisations. All evidence was of low or very low certainty. Parenting interventions</p> <p>Evidence was very uncertain from a study (33 participants) assessing the effects of a parenting intervention compared to attention control on trauma-related symptoms, and psychological wellbeing symptoms (postpartum depression), in mothers who had experienced childhood maltreatment and were experiencing current parenting risk factors. Evidence suggested that parenting interventions may improve parent-child relationships slightly compared to usual service provision (SMD 0.45, 95% CI -0.06 to 0.96; I2 = 60%; 2 studies, 153 participants; low-certainty evidence). There may be little or no difference between parenting interventions and usual perinatal service in parenting skills including nurturance, supportive presence and reciprocity (SMD 0.25, 95% CI -0.07 to 0.58; I2 = 0%; 4</p>
--	--	--	--	--	--	--

						<p>studies, 149 participants; low-certainty evidence). No studies assessed the effects of parenting interventions on parents' substance use, relationship quality or self-harm.</p> <p>Psychological interventions Psychological interventions may result in little or no difference in trauma-related symptoms compared to usual care (SMD -0.05, 95% CI -0.40 to 0.31; I2 = 39%; 4 studies, 247 participants; low-certainty evidence). Psychological interventions may make little or no difference compared to usual care to depression symptom severity (8 studies, 507 participants, low-certainty evidence, SMD -0.34, 95% CI -0.66 to -0.03; I2 = 63%). An interpersonally focused cognitive behavioural analysis system of psychotherapy may slightly increase the number of pregnant women who quit smoking compared to usual smoking cessation therapy and prenatal care (189 participants, low-certainty evidence). A psychological intervention may slightly improve parents' relationship quality compared to usual care (1 study, 67 participants, low-certainty evidence). Benefits for parent-child relationships were very uncertain (26 participants, very low-certainty evidence), while there may be a slight improvement in parenting skills compared to usual care (66 participants, low-certainty evidence). No studies assessed the effects of psychological interventions on parents' self-harm.</p> <p>Service system approaches One service system approach assessed the effect of a financial empowerment education programme, with and without trauma-informed peer support, compared to usual care for parents with low incomes. The interventions increased depression slightly (52 participants, low-certainty evidence). No studies assessed the effects of service system interventions on parents' trauma-related</p>
--	--	--	--	--	--	--

							<p>symptoms, substance use, relationship quality, self-harm, parent-child relationships or parenting skills.</p> <p>AUTHORS' CONCLUSIONS</p> <p>There is currently a lack of high-quality evidence regarding the effectiveness of interventions to improve parenting capacity or parental psychological or socio-emotional wellbeing in parents experiencing CPTSD symptoms or who have experienced childhood maltreatment (or both). This lack of methodological rigour and high risk of bias made it difficult to interpret the findings of this review. Overall, results suggest that parenting interventions may slightly improve parent-child relationships but have a small, unimportant effect on parenting skills. Psychological interventions may help some women stop smoking in pregnancy, and may have small benefits on parents' relationships and parenting skills. A financial empowerment programme may slightly worsen depression symptoms. While potential beneficial effects were small, the importance of a positive effect in a small number of parents must be considered when making treatment and care decisions. There is a need for further high-quality research into effective strategies for this population.</p>
Jones, Melanie G.; Rice, Simon M.; Cotton, Susan M.	2019	Incorporating animal-assisted therapy in mental health treatments for adolescents: A systematic review of canine assisted psychotherapy	PloS one	14	1	e021076 1	<p>INTRODUCTION: As interest in Animal-Assisted Interventions (AAI) grows, there is increasing need to differentiate informal activities from formal and professionally directed therapies, including mental health focussed Canine-Assisted Psychotherapy (CAP). There have been no reviews focusing exclusively on CAP and the distinct developmental period of adolescence. The aims of this study were to identify the characteristics of CAP interventions, their impacts and their acceptability, tolerability and feasibility for adolescents with mental</p>

						<p>health disorders. METHOD: A systematic review identified studies incorporating canines into mental health treatments for adolescents aged 10-19 years. Studies reporting qualitative or quantitative psychological or psychosocial outcomes were included. RESULTS: Seven studies were scrutinised. Intervention characteristics varied, including a range of formats, settings, locations, doses, and facilitators. Information on the role of the canines in sessions was sparse. CAP had a positive impact on primary diagnoses and symptomatology, conferring additional benefits to standard treatments for internalising disorders, post-traumatic stress disorder, and equivalent effects for anxiety, anger and externalising disorders. CAP was associated with positive impacts on secondary factors including increased engagement and socialisation behaviours, and reductions in disruptive behaviours within treatment sessions. Global functioning also improved. There was insufficient evidence that CAP improved factors associated with self-esteem, subjective wellbeing, or coping. Good attendance and retention rates indicated high levels of acceptability. Moderate to high tolerability was also indicated. Feasibility may be limited by additional training and logistical requirements. RECOMMENDATIONS: We recommend the development of theoretically informed, standardised (manualised) intervention protocols that may subsequently form the basis of efficacy and effectiveness testing. Such protocols should clearly describe canine-participant-facilitator interactions via a formalised nomenclature; spontaneous (animal-led), adjunctive (facilitator-led), and experiential (participant-led). CONCLUSIONS: There is emerging evidence to suggest that CAP improves the efficacy of mental health treatments in self-selected</p>
--	--	--	--	--	--	---

							adolescent populations via reductions in primary symptomatology, and via secondary factors that improve therapeutic processes and quality, such as engagement and retention.
Jones, Tracy L.; Garzon, Fernando L.; Ford, Kristy M.		Christian accommodative mindfulness in the clinical treatment of shame, depression, and anxiety: Results of an N-of-1 time-series study	Spirituality in Clinical Practice	10	2		Mindfulness-based treatments have shown efficacy for a variety of conditions; however, some religious populations may have concerns with the strategies due to the Buddhist roots of the interventions. Some Christians suffering with mental health conditions can be reluctant to seek professional services for fear of being given treatments that will contradict or disregard their cultural and spiritual belief systems. Therefore, adaptations to evidence-based mindfulness interventions are needed for therapists to use with such clients. The current study incorporated explicitly religious constructs to create a Christian accommodative mindfulness (CAM) protocol that was used with a small group of Christian psychotherapy clients seeking treatment for symptoms of depression or anxiety. Shame, which is often at the root of many psychological and spiritual health conditions, was also measured as were a variety of resiliency factors to determine the effectiveness of the CAM protocol in a real-world, clinical setting. Results from this N-of-1 time-series study using five subjects revealed significant effect sizes (more than half of the total individual effect sizes measured were found to be “very effective”) that associate CAM with decreased depression, anxiety, and shame and increased resiliency measures in the sample. These results are discussed, limitations acknowledged, and recommendations for further research are given. (PsycInfo Database Record (c) 2023 APA, all rights reserved)

Jongsma, Karin; Perry, Julia; Schickanz, Silke; Radenbach, Katrin	2020	Motivations for people with cognitive impairment to complete an advance research directive - a qualitative interview study	BMC psychiatry	20	1	360	<p>BACKGROUND: Research with persons with dementia is important to better understand the causes of dementia and to develop more effective diagnostics, therapies, and preventive measures. Advance Research Directives (ARDs) have been suggested as a possible solution to include persons with dementia in research in an ethically sound way. Little is known about how people, especially those affected by cognitive impairment, understand and regard the use of ARDs, as empirical studies are mainly conducted with healthy, non-cognitively impaired, participants. METHODS: This qualitative study, a sub-study of a larger study on the evaluation of ARDs in the context of dementia research in Germany, consists of semi-structured in-depth interviews with 24 persons with cognitive impairment. RESULTS: Our results indicate that most participants consider ARDs a valuable tool for allowing them to make their own decisions. Many would prefer to draft an ARD when they are still healthy or soon after the diagnosis of cognitive impairment. Participants suggested that the completion of ARDs can be advanced with the provision of practical support and increased dissemination of information on ARDs in society. CONCLUSION: Persons with subjective or mild cognitive impairment (SCI/MCI) suggested several motivating factors and concerns for completing an ARD. Clinicians need to be trained to accommodate patients' needs for sufficient and adequate information. Furthermore, a standardised, partly pre-formulated template could be helpful for drafting an ARD. As such tested templates are currently not yet available, this addresses the urgent need for more translational and implementation research for the use of ARDs.</p>

Joos, Wilhelm	2017	Wie die Seele im Krper schwingt! - Autonomes Nervensystem und Herzratenvariabilität als somatischer Marker					Die Bedeutung der Ganzheitlichkeit der Systemkonzeption Mensch (Krper, Seele, Geist) in modernen Konzepten der Psychosomatik und deren Relevanz in einer individuellen erfahrungsorientierten Therapiegestaltung wird herausgearbeitet. Dabei wird deutlich gemacht, dass auch die Schwingungen des Herzens - also die Herzfrequenzvariabilität (HRV) - durch das neuronale Netzwerk des autonomen Nervensystems verursacht werden. Sie ist die Energieform des Lebendigen. Durch die neuronalen Schwingungsmuster des peripheren und zentralen autonomen Nervensystems sind Krper, Seele und Geist aufs Engste miteinander verbunden. Sie bilden eine untrennbare Einheit.
Josek, Anna Katharina; Schaich, Anja; Braakmann, Diana; Assmann, Nele; Jauch-Chara, Kamila; Arntz, Arnoud; Schweiger, Ulrich; Fassbinder, Eva	2023	Chairwork in schema therapy for patients with borderline personality disorder-A qualitative study of patients' perceptions	Frontiers in psychiatry	14		1180839	OBJECTIVE: Chairwork is one of the core experiential techniques of Schema Therapy (ST) which is used in the treatment of patients with borderline personality disorder (BPD). However, little is known about how people with BPD experience chairwork. The aim of this study was to explore the experiences of patients with BPD with chairwork in ST. METHOD: Qualitative data were collected through semi-structured interviews with 29 participants with a primary diagnosis of BPD who experienced chairwork as part of their ST treatment. The interview data were analyzed using qualitative content analysis. FINDINGS: Many participants reported initial skepticism, and difficulties with engaging in chairwork. Specific therapist behaviors as well as some external (e.g., restricted facilities, noise) and internal factors (especially feeling ashamed or ridiculous) were named as hindering factors. Participants described several therapist behaviors facilitating chairwork such as providing safety, clear guidance through the process as well as flexible application of the technique according to their needs,

							and sufficient time for debriefing. Participants experienced emotional pain and exhaustion as short-term effects of the technique. All participants reported positive long-term effects including an improved understanding of their mode model as well as positive mode changes (e.g., less Punitive Parent and more Healthy Adult Mode), greater self-acceptance, improvements in coping with emotions and needs as well as improvements in interpersonal relationships. CONCLUSIONS: Chairwork is experienced as an emotionally demanding but valuable technique. Based on the participants' statements, the delivery of chairwork can be optimized which can help to improve treatment outcome.
Josiah, Nia; Shoola, Hakeem; Rodney, Tamar; Arscott, Joyell; Ndzi, Maureen; Bush, Ashley D.; Wilson, Patty R.; Jacques, Keilah; Baptiste, Diana-Lyn; Starks, Shaquita	2023	Addressing systemic racism and intergenerational transmission of anxiety using Bowenian family therapy with African American populations: A Discursive paper	Journal of advanced nursing	79	5	1714–1723	AIM: To examine the intergenerational impact of systemic racism on mental health, depicting the evolution and patterns of anxiety symptoms and the application of the Bowenian family therapy to understand the interrelatedness and long-standing impact of intergenerational trauma in African American families. This article highlights interventions that increase awareness of and promotes physical and mental health for African American populations. DESIGN: Discursive Paper. METHOD: Searching literature published between 2012 and 2022 in PubMed, SCOPUS, EBSCO Host and Google Scholar, we explored factors associated with systemic racism and generational anxiety. DISCUSSION: Evidence-based literature supports the application of the Bowenian family therapy theoretical framework to understand the intergenerational impact of systemic racism and to address the transmission of anxiety symptoms in African American populations. CONCLUSION: Culturally appropriate interventions are

							<p>needed to decrease anxiety symptoms in an attempt to heal intergenerational trauma and to improve family dynamics in African American populations. IMPACT TO NURSING PRACTICE: Nurses play an integral role in providing holistic quality patient-centred care for African American populations who have experienced racial trauma. It is critical for nurses to implement culturally responsive and racially informed care with patients that focuses on self-awareness, health promotion, prevention and healing in efforts to address racial trauma. Application of Bowenian family therapy can aid in the reduction of both intergenerational transmission of racial trauma and generational anxiety. NO PATIENT OR PUBLIC CONTRIBUTION: There was no patient or public involvement in the design or drafting of this discursive paper. The authors reviewed the literature to develop a discussion.</p>
Joyce, Emmeline; Tai, Sara; Gebbia, Piersanti; Mansell, Warren	2017	What are People's Experiences of a Novel Cognitive Behavioural Therapy for Bipolar Disorders? A Qualitative Investigation with Participants on the TEAMS Trial	Clinical psychology & psychotherapy	24	3	712-726	<p>UNLABELLED Background Psychological interventions for bipolar disorders typically produce mixed outcomes and modest effects. The need for a more effective intervention prompted the development of a new cognitive behavioural therapy, based on an integrative cognitive model ('Think Effectively About Mood Swings' [TEAMS] therapy). Unlike previous interventions, TEAMS addresses current symptoms and comorbidities, and helps clients achieve long-term goals. A pilot randomized controlled trial (the TEAMS trial) of the therapy has recently concluded. This study explored participants' experiences of TEAMS, recommendations for improvement and experiences of useful changes post-therapy. Methods Fourteen TEAMS therapy participants took part in semi-structured interviews. Their accounts were analysed</p>

						<p>using interpretative thematic analysis. Two researchers coded the dataset independently. Member checks were conducted of the preliminary themes. Results Two overarching themes; 'useful elements of therapy' and 'changes from therapy' encompassed 12 emerging subthemes. Participants appreciated having opportunities to talk and described the therapy as person-centred and delivered by caring, approachable and skilled therapists. Some recommended more sessions than the 16 provided. Helpful therapeutic techniques were reported to be, normalization about moods, methods to increase understanding of moods, relapse-prevention, reappraisal techniques and metaphors. However, some did not find therapeutic techniques helpful. Post-therapy, many reported changes in managing mood swings more effectively and in their thinking (although some participants reported changes in neither). Many described increased acceptance of themselves and of having bipolar disorder, increased productivity and reduced anxiety in social situations.</p> <p>Conclusions The present study evaluates participants' therapy experiences in detail, including aspects of therapy viewed as helpful, and meaningful post-therapy outcomes. Copyright © 2016 John Wiley & Sons, Ltd.</p> <p>KEY PRACTITIONER MESSAGE</p> <p>This is the first paper to qualitatively explore people's experiences of individual psychotherapy for bipolar disorders. It highlights elements of psychotherapy described as particularly helpful or unhelpful and the clinical changes viewed as most impactful. Participants reported benefitting in a number of ways from TEAMS therapy. They valued learning to reappraise and problem-solve situations and manage moods. Participants</p>
--	--	--	--	--	--	--

							identified TEAMS techniques as helpful, such as exploring advantages and disadvantages of moods, and building healthy self-states.
Joyce, Heidi; Dring, Greg	2019	Addressing Emotional Communication in Family Relationships in the Treatment of Young People with Anorexia: A Case Study	ANZ J of Family Therapy (Australian and New Zealand Journal of Family Therapy)	40	2	203–214	
Juarascio, Adrienne S.; Manasse, Stephanie M.; Espel, Hallie M.; Schumacher, Leah M.; Kerrigan, Stephanie; Forman, Evan M.	2017	A Pilot Study of an Acceptance-based Behavioral Treatment for Binge Eating Disorder	Journal of contextual behavioral science	6	1	1–7	While existing treatments produce remission in a relatively large percentage of individuals with binge eating disorder (BED), room for improvement remains. Interventions designed to increase emotion regulation skills and clarify one's chosen values may be well-suited to address factors known to maintain BED. The current study examined the preliminary efficacy of a group-based treatment, Acceptance-based Behavioral Therapy (ABBT), in a small open trial (n=19), as well as the relationship between changes in hypothesized mechanisms of action and outcomes. ABBT includes the behavioral components of cognitive behavioral treatment for BED and emotion-focused strategies from acceptance and commitment therapy and dialectical behavioral therapy. Results from generalized linear multilevel modeling revealed significant fixed linear effects of time on depression, quality of life, global eating pathology, and binge frequency (all ps < .05). Global eating disorder symptoms appeared to improve rapidly from pre- to mid-treatment, and continued to improve toward post-treatment and follow-up, but at a slower rate. Binge

							frequency decreased rapidly from pre- to mid-treatment, followed by a slight increase at post-treatment and a reduction again by follow-up. Improvements in experiential acceptance were strongly and consistently related to decreases in overall eating pathology across several measures ($r_s = .35-.54$). Additionally, greater access to emotion regulation strategies was strongly related to decreases in overall eating pathology ($r = .67$). Preliminary results support the efficacy of this novel treatment approach and indicate that additional research on ABBT for BED is warranted.
Jull, Janet; Köpke, Sascha; Smith, Maureen; Carley, Meg; FINDERUP, Jeanette; Rahn, Anne C.; Boland, Laura; Dunn, Sandra; Dwyer, Andrew A.; Kasper, Jürgen; Kienlin, Simone Maria; Légaré, France; Lewis, Krystina B.; Lyddiatt, Anne; Rutherford, Claudia; Zhao, Junqiang; Rader, Tamara;	2021	Decision coaching for people making healthcare decisions	The Cochrane database of systematic reviews	11	11	CD013385	BACKGROUND: Decision coaching is non-directive support delivered by a healthcare provider to help patients prepare to actively participate in making a health decision. 'Healthcare providers' are considered to be all people who are engaged in actions whose primary intent is to protect and improve health (e.g. nurses, doctors, pharmacists, social workers, health support workers such as peer health workers). Little is known about the effectiveness of decision coaching. OBJECTIVES: To determine the effects of decision coaching (I) for people facing healthcare decisions for themselves or a family member (P) compared to (C) usual care or evidence-based intervention only, on outcomes (O) related to preparation for decision making, decisional needs and potential adverse effects. SEARCH METHODS: We searched the Cochrane Library (Wiley), Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE (Ovid), Embase (Ovid), PsycINFO (Ovid), CINAHL (Ebsco), Nursing and Allied Health Source (ProQuest), and Web of Science from database inception to June 2021. SELECTION CRITERIA: We included randomised controlled trials (RCTs) where the intervention was

Graham, Ian D.;
Stacey, Dawn

provided to adults or children preparing to make a treatment or screening healthcare decision for themselves or a family member. Decision coaching was defined as: a) delivered individually by a healthcare provider who is trained or using a protocol; and b) providing non-directive support and preparing an adult or child to participate in a healthcare decision. Comparisons included usual care or an alternate intervention. There were no language restrictions. DATA COLLECTION AND ANALYSIS: Two authors independently screened citations, assessed risk of bias, and extracted data on characteristics of the intervention(s) and outcomes. Any disagreements were resolved by discussion to reach consensus. We used the standardised mean difference (SMD) with 95% confidence intervals (CI) as the measures of treatment effect and, where possible, synthesised results using a random-effects model. If more than one study measured the same outcome using different tools, we used a random-effects model to calculate the standardised mean difference (SMD) and 95% CI. We presented outcomes in summary of findings tables and applied GRADE methods to rate the certainty of the evidence. MAIN RESULTS: Out of 12,984 citations screened, we included 28 studies of decision coaching interventions alone or in combination with evidence-based information, involving 5509 adult participants (aged 18 to 85 years; 64% female, 52% white, 33% African-American/Black; 68% post-secondary education). The studies evaluated decision coaching used for a range of healthcare decisions (e.g. treatment decisions for cancer, menopause, mental illness, advancing kidney disease; screening decisions for cancer, genetic testing). Four of

						<p>the 28 studies included three comparator arms. For decision coaching compared with usual care (n = 4 studies), we are uncertain if decision coaching compared with usual care improves any outcomes (i.e. preparation for decision making, decision self-confidence, knowledge, decision regret, anxiety) as the certainty of the evidence was very low. For decision coaching compared with evidence-based information only (n = 4 studies), there is low certainty-evidence that participants exposed to decision coaching may have little or no change in knowledge (SMD -0.23, 95% CI: -0.50 to 0.04; 3 studies, 406 participants). There is low certainty-evidence that participants exposed to decision coaching may have little or no change in anxiety, compared with evidence-based information. We are uncertain if decision coaching compared with evidence-based information improves other outcomes (i.e. decision self-confidence, feeling uninformed) as the certainty of the evidence was very low. For decision coaching plus evidence-based information compared with usual care (n = 17 studies), there is low certainty-evidence that participants may have improved knowledge (SMD 9.3, 95% CI: 6.6 to 12.1; 5 studies, 1073 participants). We are uncertain if decision coaching plus evidence-based information compared with usual care improves other outcomes (i.e. preparation for decision making, decision self-confidence, feeling uninformed, unclear values, feeling unsupported, decision regret, anxiety) as the certainty of the evidence was very low. For decision coaching plus evidence-based information compared with evidence-based information only (n = 7 studies), we are uncertain if decision coaching plus evidence-based information compared with evidence-based information only improves any outcomes (i.e.</p>
--	--	--	--	--	--	--

							feeling uninformed, unclear values, feeling unsupported, knowledge, anxiety) as the certainty of the evidence was very low. AUTHORS' CONCLUSIONS: Decision coaching may improve participants' knowledge when used with evidence-based information. Our findings do not indicate any significant adverse effects (e.g. decision regret, anxiety) with the use of decision coaching. It is not possible to establish strong conclusions for other outcomes. It is unclear if decision coaching always needs to be paired with evidence-informed information. Further research is needed to establish the effectiveness of decision coaching for a broader range of outcomes.
Jun, Won Hee; Choi, Eun Joung	2020	The relationship between community integration and mental health recovery in people with mental health issues living in the community: A quantitative study	Journal of psychiatric and mental health nursing	27	3	296–307	WHAT IS KNOWN ON THE SUBJECT?: Mental health treatments have become patient-centred. Evaluating recovery in people with mental health difficulties living in the community can help to develop better client-centred services. Community integration is critical to recovery in patients with mental health difficulties. WHAT DOES THIS PAPER ADD TO EXISTING KNOWLEDGE?: This is the first study to use a single integrated measure of mental health recovery to evaluate the effect of community integration. Physical community integration was the easiest goal for most to reach. Developing independence/self-actualization was harder. In mental health recovery, most people were able to overcome stuckness. Developing abilities for basic functioning was harder. Participating in mental health centre day programmes promoted mental health recovery in people with mental health difficulties living in the community. Independence/self-actualization, psychological integration and social support improved mental health recovery in people with mental health difficulties living in the community. WHAT ARE THE IMPLICATIONS FOR PRACTICE?: There is a need to

						<p>develop and actively promote programmes that attract people with mental health difficulties living in the community so that they will actively use mental health centre services. Offering systematic social skills training and occupational rehabilitation therapy to people with mental health difficulties living in the community may help them function independently. Mental health service programmes should provide volunteer opportunities for people with mental health difficulties living in the community to facilitate a sense of belonging. Mental health nurses should serve as a social support resource for people with mental health difficulties living in the community by providing education to family and friends on how to support patients' recovery, and invigorating integration projects such as "making healthy friends."</p> <p>Abstract Introduction Although community integration of people with mental health difficulties and a consumer-centred recovery paradigm are of global importance, little research has been conducted on community integration factors that directly affect mental health recovery. Aim This study investigated the relationship between community integration and mental health recovery in people with mental health difficulties living in the community in South Korea. Method Data were collected from 155 people with mental health difficulties living in the community, using the Self-Reporting Scale of Community Integration and the Mental Health Recovery Measure (Korean version), and analysed using hierarchical regression analysis. Results Among the community integration subscales, independence/self-actualization, psychological integration and social support were significant factors in mental health recovery, explaining 47.3% of the variance. Discussion An</p>
--	--	--	--	--	--	--

							<p>effective intervention strategy for mental health recovery of people with mental health difficulties living in the community may reinforce community integration by carefully considering independence/self-actualization, psychological integration and social support.</p> <p>Implications for practice Mental health nurses should provide intervention to people with mental health difficulties living in the community to help them develop strategies for functioning independently, experiencing a sense of achievement and developing a sense belonging in the community.</p>
<p>Junne, Florian; Wild, Beate; Resmark, Gaby; Giel, Katrin E.; Teufel, Martin; Martus, Peter; Ziser, Katrin; Friederich, Hans- Christoph; Zwaan, Martina de; Löwe, Bernd; Dinkel, Andreas; Herpertz, Stephan; Burgmer, Markus; Tagay, Sefik; Rothermund, Eva; Zeeck, Almut; Herzog,</p>	2019	<p>The importance of body image disturbances for the outcome of outpatient psychotherapy in patients with anorexia nervosa: Results of the ANTOP-study</p>	<p>European eating disorders review : the journal of the Eating Disorders Association</p>	27	1	49–58	<p>This study investigates the role of body image self-appraisal in predicting the outcomes of outpatient psychotherapy in patients with anorexia nervosa (AN). Multiple linear regression analyses and a path-analysis model were applied to test the study hypotheses that body image at baseline predicts treatment outcomes of outpatient psychotherapy in patients with AN at follow-up measurement. The analyses were conducted as secondary analyses in a subgroup (n = 148) of the anorexia nervosa treatment of outpatient-cohort (ANTOP-study) (N = 242) of patients with AN. The results show that Negative Evaluation of the Body at baseline predicts perceived stress during psychotherapy, which in turn predicts depressive symptoms at the end of therapy which in turn predicts the outcomes body mass index and EDI-2 sum score at 12 months follow-up. The results underline the importance of body image disturbance in the course of AN and call for body image as a central target of psychotherapeutic interventions in patients with AN.</p>

Wolfgang; Zipfel, Stephan							
Juszczyk-Kalina, A.; Holas, P.; Farchione, T. J.	2023	Effectiveness and mediators of change of an online CBT intervention for students with adjustment disorder-study protocol for a randomized controlled trial	Trials	24	1	777	<p>BACKGROUND: Adjustment problems and disorders are highly prevalent among university students worldwide. These problems can cause significant interference in academic and social functioning and increase vulnerability to other mental health disorders. Unfortunately, only half of students in need receive psychological help. Furthermore, few studies have evaluated psychological interventions for adjustment disorders in students. New, more scalable forms of treatment for students with an adjustment disorder need to be developed, evaluated, and implemented. The study aims to determine the effectiveness of an online transdiagnostic cognitive behavioural intervention for students experiencing adjustment disorder and to assess mediators of change. METHOD/DESIGN: In this three-arm randomized controlled trial, we plan to recruit 214 Polish students diagnosed with an adjustment disorder. Participants who meet initial eligibility criteria will be randomly assigned to one of three 6-week conditions: (1) online cognitive behavioural therapy intervention based on an existing, empirically supported transdiagnostic protocol, the unified protocol; (2) online progressive muscle relaxation training as an active control group; or (3) waiting-list control group. Both interventions are asynchronous, interactive, and include minimal amount of therapist support. Assessments will consist of self-report questionnaires, daily diary measures, and neurocognitive tasks for evaluating cognitive functioning. These will be conducted at baseline, post-treatment, and 1-month follow-up. Daily diary measures will be taken during the first and last week of treatment (or waitlist</p>

						<p>period). Primary outcome measures will include adjustment disorder severity; secondary outcome measures will consist of other negative (psychopathology: depression, anxiety, and stress) and positive (life satisfaction) indexes of mental health as well as process measures (e.g. mindfulness, experiential avoidance, cognitive fusion). DISCUSSION: To our knowledge, the current study is the first to evaluate the effectiveness of a psychological intervention for students with adjustment disorder. Therefore, it may have important practical implications for students with this disorder. It can potentially guide the development of a scalable, validated treatment option. TRIAL REGISTRATION: Clinical Trials, NCT05768308, registered 14 March 2023, https://www.clinicaltrials.gov/ct2/show/NCT05768308.</p>	
<p>Kaczurkin, Antonia N.; Asnaani, Anu; Zhong, Jody; Foa, Edna B.</p>	<p>2016</p>	<p>The Moderating Effect of State Anger on Treatment Outcome in Female Adolescents With PTSD</p>	<p>J. Traum. Stress (Journal of Traumatic Stress)</p>	<p>29</p>	<p>4</p>	<p>325–331</p>	<p>Trauma experienced in childhood and adolescence negatively affects the development of adaptive regulation of emotions and is associated with greater symptoms of anger. Prior research has suggested that high levels of anger may impede the outcome of treatment in adults with posttraumatic stress disorder (PTSD). The current study investigated whether high levels of anger resulted in poorer treatment outcomes in adolescent girls with PTSD. Participants included 61 female adolescent survivors of sexual abuse or assault who were randomized to either prolonged exposure for adolescents (PE-A) or client-centered therapy (CCT) for traumatized children for 8-14 weekly sessions. Participants were followed for 12 months posttreatment. High levels of state anger at baseline were associated with less improvement in PTSD symptoms in the CCT group than the PE-A group ($d = 0.62$). The moderating effects of state anger on</p>

						improvement in PTSD symptoms was significant with emotion regulation difficulties, which may underlie anger symptoms ($d = 0.58$) in the model. The results of this study suggested that high state anger was less of an impediment to treatment of PTSD for those receiving PE-A than those receiving less differentiated approaches such as CCT.	
Kahn, Michal; Ronen, Alon; Apter, Alan; Sadeh, Avi	2017	Cognitive-behavioral versus non-directive therapy for preschoolers with severe nighttime fears and sleep-related problems	Sleep medicine	32		40–47	<p>OBJECTIVE: To compare the efficacy of a developmentally appropriate cognitive-behavioral therapy protocol for preschoolers with severe nighttime fears and sleep-related problems, with an active control treatment.</p> <p>METHODS: Ninety children aged four to six years (63% boys) with severe nighttime fears and their parents were randomized to either cognitive-behavioral therapy including parent involved play (CBT-PIP) or to a structurally equivalent non-directive treatment (TEPT; triadic expressive play therapy). Treatment conditions were also equivalent in parent- and child-rated credibility and expectancy, and in therapist-rated compliance. Children and parents were assessed at baseline, during the first intervention week and four weeks after treatment. Measures included actigraphy, daily sleep logs, structured diagnostic interviews and parent questionnaires.</p> <p>RESULTS: Significant reductions were observed in nighttime fears and objectively and subjectively measured sleep disruptions in both intervention groups following treatment. Parent reports indicated more advantageous outcomes for CBT-PIP compared to TEPT, with greater reductions in sleep problems and co-sleeping as well as higher customer satisfaction in the former group.</p> <p>CONCLUSIONS: While CBT-PIP showed no significant advantage compared to the active control in reducing fears or in improving</p>

							objectively measured sleep, it was significantly more beneficial in reducing the adverse behavioral features of nighttime fears.
Kailanko, Sari; Wiebe, Stephanie A.; Tasca, Giorgio A.; Laitila, Aarno A.	2022	Impact of repeating somatic cues on the depth of experiencing for withdrawers and pursuers in emotionally focused couple therapy	Journal of marital and family therapy	48	3	693–708	Emotionally Focused Couple Therapy, an experiential modality, views emotion central to therapeutic change. In this exploratory study, we examined therapists' repetition of somatically focused interventions (therapist verbalizing somatic cues, such as facial expressions) and their impact on clients' emotional experiencing in-session. We also assessed difference for withdrawing versus pursuing partners. The sample included 13 EFT therapists who worked with one couple each for a single session. From transcripts we coded therapists' repetition of somatically focused interventions and clients' depth of experiencing pre-and post-intervention. Multilevel modeling demonstrated that a higher number of repetitions of somatically focused interventions predicted greater increase in depth of experiencing, unlike length of time spent repeating interventions. Somatically focused interventions resulted in greater increase in depth of experiencing for withdrawing as compared to pursuing partners. The results of this exploratory study suggest that such interventions may be a specific technique of EFT therapists that enhances emotional experiencing especially among withdrawing partners.
Kailanko, Sari; Wiebe, Stephanie A.; Tasca, Giorgio A.; Laitila, Aarno A.; Allan, Robert	2022	Somatic experience of emotion in emotionally focused couple therapy: Experienced trainer	Journal of marital and family therapy	48	3	677–692	In general, arousal of emotions is often felt and expressed as a somatic experience in the body. In Emotionally Focused Couple Therapy (EFT), the deepening of emotional experiencing enables therapeutic change. This research explores the experiences of eight experienced EFT trainer therapists regarding their somatic experiences in their work with couples. Using interpretative phenomenological analysis of transcribed in-depth

		therapists' views and experiences				interviews, this research data yielded three core themes that captured therapists' experiences of using their own and couples' somatic experiences in therapy: (1) the importance and relevance of somatic experiences, (2) therapists' use of their own somatic experiences, and (3) working with clients' somatic experiences. The findings suggest that therapists do focus on their own and couples' somatic experiences in their work with couples, and that EFT therapists could benefit from a map to guide therapists how to focus on felt, somatic experiences as a way of maintaining an emphasis on emotional experience.
Kaimal, Girija; Walker, Melissa S.; Herres, Joanna; Berberian, Marygrace; DeGraba, Thomas J.		Examining associations between montage painting imagery and symptoms of depression and posttraumatic stress among active-duty military service members	Psychology of Aesthetics, Creativity, and the Arts	16	1	Art therapy has traditionally been used as a treatment approach but it can also be applied successfully as a clinical behavioral health assessment tool in the care of military service members suffering from the effects of traumatic brain injury (TBI) and operational stressors. This observational study examined patterns of associations between visual imagery (mask and montage paintings) and clinical symptoms among 240 active-duty military service members with TBI, and associated psychological health conditions to include posttraumatic stress disorder (PTSD). The service members had participated in a 4-week intensive outpatient assessment and treatment program at the Walter Reed National Military Medical Center in the United States. Themes seen in the visual imagery were examined in correlation with standardized measures of PTSD (Posttraumatic Stress Disorder Checklist: Military Version) and depressive symptoms (Patient Health Questionnaire-9). The analysis showed that certain themes, like the use of color symbolism to depict psychological states, were associated with greater PTSD and depressive symptoms at the beginning of the

							<p>program. In addition, patients who depicted themes like physical injury, psychological injury, and memories of deployment in Week 1 of the program were more likely to continue to represent them in Week 4. Depiction of themes like color metaphors and duality was associated with lower depressive symptoms at the end of the program. The findings indicate the potential clinical and prognostic value of tracking the content of visual imagery created by military service members with TBI and associated psychological health conditions. Clinical applications include the recognition that certain visual themes could indicate higher or lower levels of distress and may help guide targeted care. <p>Kaiser, Maleen; Adami, Sandra; Lucius-Hoene, Gabriele; Muller- Nordhorn, Jacqueline; Goerling, Ute; Breuning, Martina; Holmberg, Christine</p>	2021	<p>Learning-by- doing: the importance of experiential knowledge sharing for meeting the information needs of people with colorectal cancer in Germany-a qualitative study</p>	BMJ open	11	2	e038460	<p>OBJECTIVE: The aim of this article is to understand how, when and why the topics of information and information needs arise when people diagnosed with colorectal cancer (CRC) narrate their illness experiences. METHODS: Guided by principles of grounded theory, a qualitative interview study was conducted that collected a wide variety of illness experiences with CRC in Germany using maximum variation sampling. Sampling criteria included place of residence, age at interview, age at diagnosis, treatment, disease course and sociodemographic factors such as varying family backgrounds and professions. SETTING AND PARTICIPANTS: Men and women diagnosed with CRC in different parts of Germany were sought via physicians, social workers and psychologists in hospital settings, organisations offering psychosocial support for patients with cancer, self-help groups, rehabilitation centres, newspapers and personal contacts. The interviewees in the final sample (n=41) had been diagnosed with CRC</p>

						<p>between 4 weeks and 36 years prior to the interview. RESULTS: Three inter-related categories of information needs emerged from the analysis: the need for non-medical information for daily life; the challenge of integrating the bodily changes that accompany CRC in everyday life; and sources of non-medical information concerning handling daily life. Learning to live with the bodily changes of CRC in everyday life was described as a long process of learning-by-doing. While sources for medical information were clear, finding practical information was often a challenge. The best source of such information was often seen to be other people living with the disease, who shared their experiential knowledge, as well as stoma and nutritional therapists. CONCLUSION: Information needs are part of the process and struggle to normalise everyday life after a disruptive diagnosis and treatment. Providing access to practical knowledge and information from others with CRC experience may be an important resource for patient support.</p>
<p>Kaisler, Raphaela E.; Fede, Manfred; Diltsch, Ulla; Probst, Thomas; Schaffler, Yvonne</p>	2023	<p>Common mental disorders in Gestalt therapy treatment: a multiple case study comparing patients with moderate and low integrated personality structures</p>	<p>Frontiers in psychology</p>	14	1304726	<p>INTRODUCTION: Empowerment is central to self-development and growth in Gestalt therapy. The self evolves through interactions with others, forming self- and object-relations, and ego-functions. Underlying structural functions build the ability to regulate, differentiate, and integrate experiences, leading to self-, and emotion-regulation. Our study examined the self-development of seven clients with prevalent mental health issues and structural challenges, all of whom underwent 30 sessions of Gestalt therapy in a real-world individual therapy context. METHODS: Using a multiple case study approach, we contrasted two client groups: those with moderately integrated and those with low-</p>

						<p>integrated personality structures, as defined by the operationalised psychodynamic diagnostic manual. Our exploration centered on specific factors of empowerment, therapy processes, and interventions. The study's mixed-method design encompassed quantitative outcome measures (empowerment, wellbeing, psychosocial health, and severity of personality functioning), therapy diaries from both clients and therapists, and semi-structured client interviews about empowering factors in therapy. RESULTS: Both groups showed positive therapy outcomes on wellbeing, psychosocial health, and empowerment. Specific empowerment-related factors included promoting experiences, relationships, and self-efficacy in the low-integrated group. Support of self-regulation was reported to be essential for successful outcomes in the moderately integrated group. While the therapy processes proceeded similarly in both groups, we observed a strong focus on body awareness-oriented interventions and promotion of verbalisation in the low-integrated group and a relationship-oriented emphasis in the moderately integrated group. Emotional experience linked to positive experience was limited in the low-integrated group, suggesting an impairment of emotional processing, including bodily felt feelings. No change was reported in the level of personality functioning after 30 sessions in both groups. DISCUSSION: These results underscore the need for tailored therapeutic approaches based on the client's level of personality integration. Future research should probe the long-term effects of therapy and delve deeper into shifts in personality functioning, especially concerning emotional and bodily experiences. In practical terms, therapists should prioritize linking bodily</p>
--	--	--	--	--	--	---

							sensations with emotions for clients with low-integrated personalities. For those with moderate integration, the emphasis should be on fostering exploration, awareness, and bolstering self-regulation.
Kalantar-Zadeh, Kamyar; Forfang, Derek; Bakris, George; Martin, Kevin J.; Moe, Sharon M.; Sprague, Stuart M.	2023	Managing Phosphate Burden in Patients Receiving Dialysis: Beyond Phosphate Binders and Diet	Kidney360	4	11	1650–1656	Most patients receiving dialysis rely on dietary restriction and phosphate binders to minimize the risk of hyperphosphatemia, which is associated with increased mortality. However, dietary restriction is difficult because of hidden phosphate additives in processed foods and medications. Restriction of dietary phosphate sources such as protein may increase the risk of malnutrition. Phosphate binders, the only pharmacologic option for phosphate management since aluminum salts were introduced several decades ago, are often insufficient for binding the 1400-2500 mg of phosphate potentially consumed daily. Over the last decade, serum phosphate levels in the United States have risen, and >69% of patients receiving dialysis exhibited a most recent phosphate level >4.5 mg/dl (above the normal range), indicating an urgent need for new, more effective therapies to manage phosphate burden. Novel, nonbinder therapies such as transcellular and paracellular phosphate absorption inhibitors may be used for phosphate management, and future studies should examine whether they allow fewer dietary restrictions for patients receiving dialysis, potentially improving patient quality of life and nutritional status. It is imperative that we collaborate to move beyond the restrictive approaches available today and provide patients and clinicians with an array of strategies so that they may choose the most appropriate patient-centered therapy.
Kallos-Lilly, Veronica;	2016	Wir beide. Das Arbeitsbuch zur					Vorgestellt wird die Emotionsfokussierte Therapie (EFT) in der Arbeit mit Paaren. Sie setzt beim kleinsten

Fitzgerald, Jennifer		Emotionsfokussierten Paartherapie					gemeinsamen Nenner in Paarbeziehungen an: dem grundlegenden Bedürfnis nach Liebe und Akzeptanz. In der Emotionsfokussierten Paartherapie geht es darum, die eigenen Gefühle und Bedürfnisse zu erkennen und dem Partner angemessen zu vermitteln. So können Paare ihre Beziehung auf einer tiefen emotionalen Ebene festigen. bungen und Praxisbeispiele ermöglichen die Übertragung der Interventionen in den gemeinsamen Alltag als Paar. - Inhalt: (1) Für wen haben wir dieses Buch geschrieben. Kamphausen, Anne; Roese, Hanna; Oechsle, Karin; Issleib, Malte; Zöllner, Christian; Bokemeyer, Carsten; Ullrich, Anneke	2019	Challenges Faced by Prehospital Emergency Physicians Providing Emergency Care to Patients with Advanced Incurable Diseases	Emergency medicine international	2019	3456471	INTRODUCTION: The aim of our study was to investigate challenges faced by emergency physicians (EPs) who provide prehospital emergency care to patients with advanced incurable diseases and family caregivers in their familiar home environment. METHODS: Qualitative study using semistructured interviews with open-ended questions to collect data from 24 EPs. Data were analyzed using qualitative content analysis. RESULTS: We identified nine categories of challenges: structural conditions of prehospital emergency care, medical documentation and orders, finding optimal patient-centered therapy, uncertainty about legal consequences, challenges at the individual (EP) level, challenges at the emergency team level, family caregiver's emotions, coping and understanding of patient's illness, patient's wishes, coping and understanding of patient's illness, and social, cultural, and religious background of patients and families. EPs strengthened that the integrations of specialized prehospital palliative care services improved emergency care by providing resources to patients and family caregivers, enhancing the quality and availability of medical documentation and accessibility of aftercare in emergencies. Areas of improvement that were identified were to promote emergency physicians' knowledge and skills in palliative care, communication, and family caregiver support by education and training. Furthermore, structures for better care on-site, thorough medical

						documentation, and specialized palliative care emergency facilities in hospital and prehospital care were requested. CONCLUSION: Prehospital emergency care in patients with advanced incurable diseases in their familiar home environment may be improved by training EPs in palliative care, communication, and caregiver support competences. Results underline the importance of collaborative specialized palliative care and prehospital emergency care.
Kandale, Miki; Rugenstein, Kai	2017	Das Repetitorium. Lehr- und Lernbuch für die schriftlichen Abschlussprüfungen zum Psychologischen Psychotherapeuten und zum Kinder- und Jugendlichenpsychotherapeuten				Im vorliegenden Repetitorium für die Abschlussprüfungen zum Psychologischen Psychotherapeuten und zum Kinder- und Jugendlichenpsychotherapeuten wird nicht nur eine systematische Wiederholung von Wissen präsentiert, um die Approbationsprüfung effizient zu bestehen. Darüber hinaus werden eine methodische Anleitung zur Prüfungsvorbereitung und konkrete Strategien für den Umgang mit Klausurfragen in der Prüfungssituation geboten. Das Repetitorium orientiert sich dabei an den Gegenstandskatalogen des Instituts für medizinische und pharmazeutische Prüfungsfragen (IMPP) und den Anforderungen der aktuellen Klausuren, wobei es das Ziel verfolgt, die mangleblichen Examensinhalte in einem Kompromiss aus notwendiger Ausführlichkeit und möglicher Prägnanz darzustellen. Besonders relevante Inhalte sind als solche hervorgehoben und werden in ausführlichen Beispielen aus der Praxis veranschaulicht. Damit fungiert das Repetitorium zugleich als hilfreiches Lernwerkzeug und als praxisorientiertes Kompendium, das auch nach der erfolgreichen Approbation dem Psychologischen Psychotherapeuten und dem Kinder- und Jugendlichenpsychotherapeuten hilfreich sein kann. - Die vorliegende dritte, aktualisierte Auflage des Repetitoriums bietet neben bearbeiteten Inhalten vor

						<p> allem eine ausführliche Erläuterung der seit dem 01. April 2017 Anwendung findenden Psychotherapierichtlinie, um damit in bewährter Weise zuverlässige Orientierung und Sicherheit auf dem Weg zur Approbation und darüber hinaus zu geben. - Inhalt: (A) Anleitung zur Prüfungsvorbereitung und zum Umgang mit diesem Buch. Kanesaki, Hiromi; Watanabe, Kiwamu; Osugi, Kazuha; Ohara, Hiroya; Takada, Kozue; Kinoshita, Masako	2023	Utility of scratch art therapy in adult epilepsy patients with difficulties in social adaptation	Couns and Psychother Res (Counselling and Psychotherapy Research)	25	5	702-711	Abstract Objective Adult patients with epilepsy are confronted with significant psychological and psychosocial burdens. However, the role of psychological intervention to improve quality of life has not been fully established yet. The basis of art therapy is symbolic representations of inner experiences but patients may have difficulty expressing themselves. Here, we investigated utilities of scratch art therapy in Japanese adult patients with epilepsy who feel difficulties in social adaptation. Methods Seven adult epilepsy patients (four males, age: 32.1±9.9, mean±SD) treated in epilepsy clinic of our hospital, who complained of psychosocial problems and underwent psychotherapy sessions combined with art therapy, were included. Six patients had focal epilepsy and two of them were sequelae of encephalitis. They were comorbid with depression, mood disorders, anxiety, memory disturbance, and insomnia. Psychotherapy sessions were scheduled at the same day of their clinic visit, every 4-12 weeks, 60 min per day, and art therapy was performed as a part (up to 30 min, in accord with the condition of the patient) of each session. Scratch art therapy was performed by using ready-made publications. Each patient selected favorite motives of figure out of several options suggested by the therapist. Results All patients quickly adapted themselves to scratch art therapy and verbally expressed their hidden

							emotions during drawing. One female patient with emotional lability appealed that she could stab herself by pointed end of the pen. Three patients added self-motivated lines to the designed draft. Two patients realized problems to be solved and moved to other suitable therapeutic procedures. Significance The current case series study demonstrated utilities of scratch art therapy in Japanese adult patients with epilepsy who feel difficulties in social adaptation. Scratch art therapy is easy to introduce in adult epilepsy patients who have trouble expressing themselves or have uncontrollable emotions.
Karlhuber, Kerstin	2021	Pathologisches Horten vor dem Hintergrund der psychodramatischen Entwicklungstheorie. Warum genug nie gengen kann	Zeitschrift fr Psychodrama und Soziometrie	20	2	357–369	In diesem Beitrag der Zeitschrift fr Psychodrama und Soziometrie (ZPS) wird die Strung des Pathologischen Hortens unter dem Blickwinkel der psychodramatischen Entwicklungstheorie skizziert. Weiters werden die perfekten Ziele von Menschen mit Messie-Symptomatik dargestellt. Die Erfahrungen, die als Leiterin einer psychodramatischen Gruppe fr Messies gemacht wurden, werden dargestellt. (c) Springer Fachmedien Wiesbaden GmbH
Karlin, Bradley E.; Brenner, Lisa A.	2020	Improving engagement in evidence-based psychological treatments among Veterans: Direct-to-consumer outreach and pretreatment shared	Clinical Psychology: Science and Practice		14	68-28	Despite growing empirical support over the past half-century, evidence-based psychotherapies (EBPs) remain infrequently delivered. Organized efforts within large public and private systems, including the Veterans Health Administration, have brought significant optimism to closing the research-to-practice gap. Notwithstanding robust improvements, few Veterans and non-Veterans receive EBPs. The current article expands implementation knowledge and practice by extending focus of EBP implementation from provider, system, and policy-level requirements to key patient-level barriers and associated “pull strategies” for promoting interest, demand, and

		decision-making			Print)		engagement. Specifically, the article presents a public health and clinical engagement strategy and innovations developed by the authors leveraging strategic actions for increasing EBP uptake and engagement in two key areas: (a) direct-to-consumer outreach and education, and (b) pretreatment shared decision-making. (PsycInfo Database Record (c) 2021 APA, all rights reserved)
Karyotaki, Eirini; Smit, Yolba; Beurs, Derek P. de; Henningsen, Kirsten Holdt; Robays, Jo; Huibers, Marcus J. H.; Weitz, Erica; Cuijpers, Pim	2016	THE LONG-TERM EFFICACY OF ACUTE-PHASE PSYCHOTHERAPY FOR DEPRESSION: A META-ANALYSIS OF RANDOMIZED TRIALS	Depression and anxiety	33	5	370–383	<p>BACKGROUND Understanding the effectiveness of treatment for depression in both the short term and long term is essential for clinical decision making. The present meta-analysis examined treatment effects on depression and quality of life in acute-phase psychotherapeutic interventions compared to no treatment control groups for adult depression at 6 months or longer postrandomization.</p> <p>METHODS A systematic literature search resulted in 44 randomized controlled trials with 6,096 participants. Acute-phase psychotherapy was compared to control groups at 6-month or longer postrandomization. Odds ratios of a positive outcome were calculated.</p> <p>RESULTS Psychotherapy outperformed control groups at 6 months or longer postrandomization (OR = 1.92, 95% CI: 1.60-2.31, P < .001). Heterogeneity was moderate (I^2: 65, 95% CI: 53-74, P < .001). However, effects significantly decreased with longer follow-up periods. Additionally, a small positive effect of psychotherapy was observed for quality of life, while similar effects were obtained in separate analyses of each type of psychotherapy, with the exception of nondirective supportive therapy. Studies that provided booster sessions had better treatment results</p>

							<p>compared with studies that did not provide any further sessions. Finally, we found that trials on psychotherapy aimed at major depressive disorder (MDD) had better outcomes than those that were aimed at elevated depressive symptoms.</p> <p>CONCLUSIONS</p> <p>There is substantial evidence that acute-phase psychotherapy results in a better treatment effects on depression and quality of life in the long term for adult patients with depression.</p>
<p>Kass, Andrea E.; Balantekin, Katherine N.; Fitzsimmons-Craft, Ellen E.; Jacobi, Corinna; Wilfley, Denise E.; Taylor, C. Barr</p>	2017	<p>The economic case for digital interventions for eating disorders among United States college students</p>	<p>The International journal of eating disorders</p>	50	3	250–258	<p>OBJECTIVE</p> <p>Eating disorders (EDs) are serious health problems affecting college students. This article aimed to estimate the costs, in United States (US) dollars, of a stepped care model for online prevention and treatment among US college students to inform meaningful decisions regarding resource allocation and adoption of efficient care delivery models for EDs on college campuses.</p> <p>METHODS</p> <p>Using a payer perspective, we estimated the costs of (1) delivering an online guided self-help (GSH) intervention to individuals with EDs, including the costs of "stepping up" the proportion expected to "fail"; (2) delivering an online preventive intervention compared to a "wait and treat" approach to individuals at ED risk; and (3) applying the stepped care model across a population of 1,000 students, compared to standard care.</p> <p>RESULTS</p> <p>Combining results for online GSH and preventive interventions, we estimated a stepped care model would cost less and result in fewer individuals needing in-person psychotherapy (after receiving less-intensive intervention) compared to standard care, assuming everyone in need</p>

							<p>received intervention.</p> <p>CONCLUSIONS</p> <p>A stepped care model was estimated to achieve modest cost savings compared to standard care, but these estimates need to be tested with sensitivity analyses. Model assumptions highlight the complexities of cost calculations to inform resource allocation, and considerations for a disseminable delivery model are presented. Efforts are needed to systematically measure the costs and benefits of a stepped care model for EDs on college campuses, improve the precision and efficacy of ED interventions, and apply these calculations to non-US care systems with different cost structures.</p>
Kaster, Simone D.	2018	Grenz-Erfahrungen. Existenzanalytische Psychotherapie mit Geflüchteten	Existenzanalyse	35	2	87–91	<p>Im vorliegenden Artikel wird anhand eines Fallbeispiels aus der Praxis der Autorin die existenzanalytische Psychotherapie mit einem geflüchteten, traumatisierten 38-jährigen Mann aus Kamerun ausgeführt, der in seinem Heimatland aufgrund seiner politischen Aktivitäten inhaftiert worden und über einen Zeitraum von fünf Jahren physischer und psychischer Folter ausgesetzt gewesen war. Der Klient stellte sich mit den Symptomen einer posttraumatischen Belastungsstörung (PTBS) vor und dem Gefühl, "verrückt" zu werden. Zudem verstärkten der Bruch in seiner Biographie und das Gefühl des Verlustes seiner Identität als Flüchtling in einem fremden Land seine Symptome. Es wird dargestellt, wie im Therapieprozess mithilfe der Verortung der Symptome und Leiden des Klienten in den vier Grundmotivationen der Existenzanalyse und der entsprechenden Behandlung eine deutliche Veränderung und Verbesserung der Symptome beobachtet werden konnten.</p>

Katz, Michael; Hilsenroth, Mark J.	2018	Psychodynamic technique early in treatment related to outcome for depressed patients	Clinical psychology & psychotherapy	25	2	348–358	We examined the relationship between psychodynamic techniques early in treatment with reliable change in depressive symptomatology. Forty-six patients admitted for individual psychodynamic psychotherapy who received a diagnosis representative of a depressive spectrum disorder were assessed pretreatment and posttreatment through self-report of depressive symptoms. Videotapes from two early treatment sessions (3rd and 9th) were independently rated on the Comparative Psychotherapy Process Scale for use of psychodynamic-interpersonal and cognitive-behavioural techniques, with excellent interrater reliability (intraclass correlation coefficient > .75). We found a significant relationship between overall use of psychodynamic technique across early treatment ($r = .31, p = .036$), as well as specific psychodynamic techniques delivered across early treatment, with change in patient-reported depressive symptoms. Our findings suggest that focusing on affective experiencing and expression, as well as providing interpretations are particularly helpful early in psychodynamic treatment for depression. Clinical implications and future directions are discussed.
Katzmann, Josepha; Hautmann, Christopher; Greimel, Lisa; Imort, Stephanie; Pinior, Julia; Scholz, Kristin; Döpfner, Manfred	2017	Behavioral and Nondirective Guided Self-Help for Parents of Children with Externalizing Behavior: Mediating Mechanisms in a Head-To-Head Comparison	Journal of abnormal child psychology	45	4	719–730	Parent training (PT) delivered as a guided self-help intervention may be a cost- and time-effective intervention in the treatment of children with externalizing disorders. In face-to-face PT, parenting strategies have repeatedly been identified as mediating mechanisms for the decrease of children's problem behavior. Few studies have examined possible mediating effects in guided self-help interventions for parents. The present study aimed to investigate possible mediating variables of a behaviorally oriented guided self-help program for parents of children with externalizing problems compared to a nondirective

							<p>intervention in a clinical sample. A sample of 110 parents of children with externalizing disorders (80 % boys) were randomized to either a behaviorally oriented or a nondirective guided self-help program. Four putative mediating variables were examined simultaneously in a multiple mediation model using structural equation modelling. The outcomes were child symptoms of ADHD and ODD as well as child externalizing problems, assessed at posttreatment. Analyses showed a significant indirect effect for dysfunctional parental attributions in favor of the group receiving the behavioral program, and significant effects of the behavioral program on positive and negative parenting and parental self-efficacy, compared to the nondirective intervention. Our results indicate that a decrease of dysfunctional parental attributions leads to a decrease of child externalizing problems when parents take part in a behaviorally oriented guided self-help program. However, none of the putative mediating variables could explain the decrease in child externalizing behavior problems in the nondirective group. A change in dysfunctional parental attributions should be considered as a possible mediator in the context of PT.</p>
<p>Katznelson, Hannah; Falkenström, Fredrik; Daniel, Sarah I. F.; Lunn, Susanne; Folke, Sofie; Pedersen, Signe Holm; Poulsen, Stig</p>	2020	<p>Reflective functioning, psychotherapeutic alliance, and outcome in two psychotherapies for bulimia nervosa</p>	Psychotherapy	57	2	129-140	<p>Mentalization is a developmental achievement defined as the capacity to understand behavior in terms of mental states. This study investigated mentalization in psychoanalytic psychotherapy (PPT) and cognitive behavior therapy (CBT) through a secondary data analysis of findings from a randomized controlled trial for bulimia nervosa. It was hypothesized that mentalization would predict alliance and outcome in both treatments, whereas increase in mentalization was only expected after PPT. Furthermore, it was investigated whether</p>

							<p>change in mentalization predicted symptom change. A total of 70 participants with bulimia nervosa were randomized to PPT or CBT. Participants were assessed at 3 time points with the Eating Disorder Examination and the Adult Attachment Interview (rated for reflective functioning [RF]). Therapy sessions were rated with the Vanderbilt Therapeutic Alliance Scale. Higher intake RF significantly predicted better alliance, whereas no association was observed between RF and outcome. A significant interaction between time, therapy type, and RF found RF improving more in PPT than in CBT. There was a significant association between RF change and symptom change in the PPT group. The study suggests a relation between RF and psychotherapy process, whereas the relation between RF and outcome is more complex. Furthermore, PPT seems to enhance mentalization, which seems related to symptomatic improvement, suggesting that mentalization might serve as a specific mechanism of change in PPT. (PsycInfo Database Record (c) 2020 APA, all rights reserved)</p>
<p>Kawashita, Takumi; Dunnsiri, Teevit; Shu, Sara; Tran, Patrick; Agustines, Davin</p>	2019	<p>Losing Legs to Losing Everything: How Neglecting Holistic Health Devastated a Lower-limb Amputee</p>	Cureus	11	12	e6275	<p>Holistic care means addressing the patient as a person; providing high-quality care by focusing on individual needs. Our goal is to implement a survey that quantifies the patients' physical, mental, and spiritual health to enable improvements in client-centered therapy in lower-limb amputees. For this, we worked with a 43-year-old Hispanic male with a medical history of insulin-dependent diabetes complicated by sequential lower limb amputations. The second amputation cost him his job and left him homeless. The patient was hospitalized after developing severe depression, to the point that he had command auditory hallucinations to kill himself. He was discharged back into the community after a three-</p>

						<p>week hospitalization. However, he was readmitted to the hospital a week later due to a resurgence of suicidal ideation. Our team engaged the patient using the "Holistic Health and Wellness Survey" of Raymond W. Smith, which we used to assess and address various domains of his mental, spiritual, and physical health. We were able to create obtainable goals for the patient for each category on which he scored low in the health and wellness survey. The patient's overall health and attitude improved substantially through his client-centered therapy, which addressed his quantified health needs; and he began to take an active role in developing short- and long-term goals that he found attainable as he adjusted to life as a double-amputee. This case illustrates the potential for improving client-centered therapy in lower-limb amputees. We believe that providers may benefit from implementing this health and wellness survey to better assess how to provide client-centered care for their patients.</p>
Kealy, David; Seidler, Zac E.; Rice, Simon M.; Oliffe, John L.; Ogrodniczuk, John S.; Kim, Dan	2021	Challenging assumptions about what men want: Examining preferences for psychotherapy among men attending outpatient mental health clinics	Professional Psychology: Research and Practice	19-23(Electronic), 07-35-70	28-33	<p>Understanding men's preferences for outpatient mental health treatment is important in better providing responsive services that engage this population in effectual care. In psychotherapy, responding to client preferences is associated with reduced attrition and improved outcomes. Knowledge regarding men's therapy preferences, however, is limited and equivocal, particularly among men attending outpatient mental health services. The present study examined treatment preferences—with a focus on psychotherapy—in a sample of Canadian men (N = 92) attending public-funded outpatient clinics. The majority of men (45.7%) endorsed a strong preference for individual psychotherapy. This preference was associated with</p>

							higher levels of work and social impairment. Men tended to prefer therapists to teach coping strategies, explore feelings and patterns of experiences, and assist men in working with emotions. Only 20.9% of men preferred brief treatment, and 31.4% perceived a need for long-term therapy (> 1 year). Contrary to popular discourse, findings indicated respondents' preference for therapies that focus on vulnerable emotions, and many men—particularly those with greater functional impairment—reported interest in longer term, emotion-oriented psychotherapy. Kealy, David; Spidel, Alicia; Ogrodniczuk, John S.	2017	Self-conscious emotions and suicidal ideation among women with and without history of childhood sexual abuse	Couns and Psychother Res (Counselling and Psychotherapy Research)	17	4	269–275	
Kearns, Nathan T.; Contractor, Ateka A.; Weiss, Nicole H.; Blumenthal, Heidemarie	2021	Coping strategy utilization among posttraumatic stress disorder symptom severity and substance use co-occurrence typologies: A latent class analysis	Psychological Trauma: Theory, Research, Practice, and Policy	13	8	929–939	Objective: There is a lack of research on primary prevention of posttraumatic stress disorder (PTSD) symptoms and substance use among trauma-exposed populations. To guide the development of more effective prevention efforts, the current study sought to identify underlying coping mechanisms that impact PTSD–substance use co-occurrence. Method: A person-centered analytic approach (latent class analysis) examined PTSD–substance use co-occurrence typologies (classes) and identified theoretically adaptive (e.g., active coping) and maladaptive (e.g., denial) coping strategies that differentiated between classes among a sample of 1,270 trauma-exposed participants (Mage = 20.71, 73.5%

						female, 45.7% White). Results: Latent class analysis identified five distinct typologies, reflective of extant epidemiological and etiological work. Generally, behavioral disengagement and self-blame coping increased the likelihood of being in more severe PTSD–illicit substance use (e.g., cocaine) comorbidity classes. Positive reframing and planning differentiated between low and moderate illicit substance typologies with moderate PTSD severity. Venting, acceptance, and self-distraction differentiated between asymptomatic and moderate PTSD severity typologies with low illicit substance use. Conclusions: Findings identify general coping strategies associated with increased likelihood of being in more severe comorbidity typologies, as well as several unique coping strategies associated with risk of transitioning between low/moderate PTSD and illicit substance use classes. Relevant interventions (e.g., trauma psychoeducation, guilt-reduction therapy, psychological first aid) that may be targets for future prevention-oriented work are discussed. Kearns, Nathan T.; Jackson, Warren T.; Elliott, Timothy R.; Ryan, Tiffany; Armstrong, Trey W.		Differences in level of upper limb loss on functional impairment, psychological well-being, and substance use	Rehabilitation Psychology	63	1	Purpose/Objective: The present study examines associations between levels of limb loss (partial hand vs. higher levels of limb loss) and eight clinically relevant measures of functional impairment, psychological well-being, and substance use. Research Method/Design: A cross-sectional, multisite study conducted at seven prosthetic rehabilitation centers across the United States. A total of 305 participants with upper limb loss (Mage = 44.28, SD = 15.45; 68.5% male; 70.5% white) completed orally administered self-assessments of pain interference, perceived activity restrictions, posttraumatic stress disorder (PTSD), depression,

							emotional reaction to their physical condition, problematic alcohol use, prescription medication overuse, and illicit drug use. Results: Results showed individuals with partial hand loss were at significantly greater odds of endorsing pain interference and screening positive for PTSD. Results also showed level of limb loss was significantly associated with emotional reaction to their physical condition, such that participants with partial hand loss scored significantly above those with higher level limb loss. Conclusions/Implication: The current study highlights level of limb loss as an important correlate of several functional impairments and psychological measures among individuals with upper limb loss. These findings may inform clinicians and occupational therapists in their development of treatment and rehabilitation. In particular, practitioners should be cognizant of their patient's level of limb loss, as individuals with partial hand loss may be more susceptible to greater emotional reactions to their physical condition and increased psychological distress due to pain interfering with their work and elevated posttraumatic stress symptoms. Keating, Frank; Cole, Laura; Grant, Robert	2020	An evaluation of group reminiscence arts sessions for people with dementia living in care homes	Dementia (London, England)	19	3	805–821	
Keefe, John R.; Huque, Zeeshan M.; DeRubeis,	2019	In-session emotional expression	Psychotherapy	56	4	514–525	In panic-focused psychodynamic psychotherapy (PFPP), exploration and interpretation of avoided and conflicted emotions and fantasies surrounding anxiety are thought

<p>Robert J.; Barber, Jacques P.; Milrod, Barbara L.; Chambless, Dianne L.</p>		<p>predicts symptomatic and panic-specific reflective functioning improvements in panic-focused psychodynamic psychotherapy</p>				<p>to promote panic-specific reflective functioning (PSRF), which drives panic disorder improvements. Patient emotional expression within a session may be a marker of engaged processing and experiencing of affectively charged material. Degree of in-session expressed emotion, indicating both verbal and nonverbal emotions, was examined across three early therapy sessions for prediction of subsequent outcomes. We further investigated whether personality disorder traits, theorized to relate to constricted (obsessive-compulsive) or heightened (borderline) emotions, moderated this relationship. Emotional expression in Sessions 2, 5, and 10 of a 24-session PFPP protocol was assessed by blinded observers in 44 patients randomized to PFPP in a two-site randomized controlled trial of psychotherapies for panic disorder. Robust regressions were conducted to examine the relationship between average emotional expression across the measured sessions and symptom and PSRF changes subsequent to the sampled sessions, as well as moderation by personality disorder criteria, controlling for early outcomes. Higher levels of emotional expression across the early sessions predicted greater subsequent symptom and PSRF improvement. Elevations in expression of grief/sadness drove the symptomatic finding. Patients meeting more borderline criteria experienced a smaller and potentially negative relationship between emotional expression and symptom improvement. Emotional expression in PFPP may be an indicator of positive therapy process for patients without comorbid borderline personality traits, predicting prospective improvements in both a key mediator (PSRF) and symptoms. Keefe, John R.; Milrod, Barbara L.; Gallop, Robert; Barber, Jacques P.; Chambless, Dianne L.	2018	What is the effect on comorbid personality disorder of brief panic-focused psychotherapy in patients with panic disorder?	Depression and anxiety	35	3	239–247	<p>BACKGROUND No studies of psychotherapies for panic disorder (PD) have examined effects on comorbid personality disorders (PersD), yet half such patients have a PersD.</p> <p>METHODS In a randomized trial for PD with and without agoraphobia comparing Cognitive-Behavioral Therapy (CBT) and Panic-Focused Psychodynamic Psychotherapy (PFPP), PersD was assessed pre-to-post treatment with the Structured Clinical Interview for the Diagnosis of Axis-II Disorders (SCID-II). For patients completing therapy (n = 118, 54 with PersD), covariance between panic and SCID-II criteria improvements was analyzed. SCID-II diagnostic remission and recovery were evaluated. Comparative efficacy of PFPP versus CBT for improving PersD was analyzed both for the average patient, and as a function of PersD severity.</p> <p>RESULTS 37 and 17% of PersD patients experienced diagnostic PersD remission and recovery, respectively. Larger reductions in PersD were related to more panic improvement, with a modest effect size (r = 0.28). Although there was no difference between treatments in their ability to improve PersD for the average patient (d = 0.01), patients meeting more PersD criteria did better in PFPP compared to CBT (P = .007), with PFPP being significantly superior at 11 criteria and above (d = 0.66; 3 more criteria lost).</p> <p>CONCLUSIONS PersD presenting in the context of primary PD rarely resolves during psychotherapies focused on PD, and change in PersD only moderately tracks panic improvements, indicating non-overlap of the constructs.</p>
--	------	---	------------------------	----	---	---------	--

							Patients receiving panic-focused psychotherapies may require additional treatment for their PersD. PFPP may be superior at improving severe PersD, but replication of this finding is required.
Kehle-Forbes, Shannon M.; Ackland, Princess E.; Spont, Michele R.; Meis, Laura A.; Orazem, Robert J.; Lyon, Alexandra; Valenstein-Mah, Helen R.; Schnurr, Paula P.; Zickmund, Susan L.; Foa, Edna B.; Chard, Kathleen M.; Alpert, Elizabeth; Polusny, Melissa A.	2022	Divergent experiences of U.S. veterans who did and did not complete trauma-focused therapies for PTSD: A national qualitative study of treatment dropout	Behaviour research and therapy	154		104123	Prolonged Exposure (PE) and Cognitive Processing Therapy (CPT) are first-line treatments for posttraumatic stress disorder (PTSD) and have been disseminated throughout the U.S. Veterans Health Administration. Treatment non-completion is common and lessens clinical effectiveness; however, prior work has failed to identify factors consistently associated with non-completion. Semi-structured interviews were conducted with a national sample of veterans who recently completed (n = 60) or did not complete (n = 66) PE or CPT. Non-completer interviews focused on factors that contributed to veterans' decisions to drop out and efforts undertaken to complete PE/CPT. Completer interviews focused on challenges faced in completing treatment and facilitators of completion. Transcripts were coded using a mixed deductive/inductive approach; constant comparison was used to identify differences between completers and non-completers. Completers and non-completers differed in the extent of treatment-specific therapist support received, therapists' flexibility in treatment delivery, the type of encouragement offered by the care team and social supports, their interpretation of symptom worsening, the perceived impact of treatment on functioning, and the impact of stressors on their treatment engagement. Treatment-specific therapist support, more patient-centered and flexible treatment delivery, leveraging the full care team, and addressing functional concerns are potential targets for PE and CPT engagement interventions.

<p>Kehoe, Christiane E.; Havighurst, Sophie S.; Harley, Ann E.</p>	<p>2020</p>	<p>Tuning in to Teens: Investigating moderators of program effects and mechanisms of change of an emotion focused group parenting program</p>	<p>Developmental Psychology</p>	<p>56</p>	<p>3</p>	<p>623–637</p>	<p>In recent years emotion socialization theory (Eisenberg, Cumberland, & Spinrad, 1998) has begun to be used in parenting interventions, allowing an important and effective method for testing the theory. The current study is one such example, and examined moderators of program effects and mechanisms of change in an emotion-focused group parenting program, Tuning in to Teens (TINT), to determine whether an intervention with this theoretical approach would be effective in improving adolescent internalizing difficulties. Schools were randomized into intervention and control conditions. Data was collected from 225 parents and 224 youth during the young person's final year of elementary school (6th grade) and again, 10 months later in their first year of secondary school (7th grade). Those in the intervention condition received a 6-session program targeting parent emotion awareness/regulation, parental beliefs about emotion and parents' emotion coaching skills. Multilevel analyses were conducted to examine moderators of the intervention and regression analyses were conducted to examine mediators of program effects. Results showed greater benefits for intervention subgroups with high preintervention scores on youth anxiety. Parental internalizing difficulties and parental difficulties in emotion awareness/regulation did not moderate program effects. Mediation analyses supported emotion socialization theory and showed parents' who participated in the TINT parenting program reported improvements in their own awareness/regulation and emotion socialization, which were, in turn, related to reductions in youth internalizing difficulties. Keil, Sylvia	2019	Das personenzentrierte Verständnis von Psychotrauma . Zur Integration psychotraumatologischer Erkenntnisse in das Personenzentrierte Konzept	Person	23	2	110-121	Dieser Artikel beschäftigt sich mit der Frage, wie psychotraumatologische Erkenntnisse in das Personenzentrierte Therapiekonzept integriert werden können. Es wird vorgeschlagen, traumatische und posttraumatische Erfahrungen nicht als Inkongruenz, sondern als extrem strukturgebundene somato-psychische Symptome zu begreifen, die erst in der Folge organismisch erlebt werden können. In diesem Zusammenhang wird die These vertreten, dass Traumabewältigung nicht etwa bedeutet, traumatische Erfahrungen ins Selbstkonzept aufzunehmen. Die Reorganisation der Selbststruktur bzw. die Verringerung der Inkongruenz geschieht vielmehr durch die bessere Bewältigung der posttraumatischen Folgestörungen mithilfe der vorhandenen Selbststruktur. Menschen mit Entwicklungs-trauma haben in der therapeutischen Beziehung die Chance, überhaupt erst adäquate Selbststrukturen aufzubauen. Es werden die therapietheoretischen Implikationen als Konsequenz dieser persönlichkeits-theoretischen Positionen diskutiert.
Keil, Sylvia; Korunka, Christian; Topaloglou, Helena M.; Kurl, Neena; Kfer- Schmid, Gerald	2021	Forschung in der Personenzentrierten und Experienziellen Psychotherapie 2008-2019 . Ein narrativer Review - 1. Teil	Person	25	1	76-90	File, Hutterer, Keil, Korunka und Macke-Bruck beschäftigten sich in einem 2008 veröffentlichten Artikel vorrangig mit publizierten Wirksamkeitsstudien bei Klienten-/Personenzentrierte und Experienzielle Psychotherapien aus den Jahren 1991 bis 2008. Aktuell wurde systematisch der Frage nachgegangen, welche Entwicklungen es in den elf Folgejahren gegeben hat. Der entstandene narrative Review setzt sich mit der Forschung von am personenzentrierten Ansatz orientierten Psychotherapien breiter auseinander. Im Zentrum stehen 343 in fach einschlägigen Zeitschriften publizierte Forschungsarbeiten der Jahre 2008 bis 2019. Im 1. Teil werden die zugeordneten Ergebnisse aus Metaanalysen,

							Fallstudien und empirisch beforschten Aspekten des Psychotherapieprozesses prsentiert.
Keil, Wolfgang W.; Stumm, Gerhard	2018	Arbeit mit dem Experiencing					Vernderung kommt demnach zustande, wenn eine Person im Rahmen einer bedeutungsvollen persnlichen Beziehung sich intensiv mit ihrem eigenen inneren Erleben ("experiencing") beschftigt. Beim Experiencing handelt es sich um einen zentralen Bereich menschlichen Erlebens, den Bereich des gesamten gefhlten impliziten Wissens. Gendlin definiert es als prkonzeptuelles und im Krperlichen (in der eigenen Mitte) sprbares, noch undifferenziertes, aber implizites und vieldimensionales Erleben, aus dem in der Folge (persnliche) Bedeutungen, Gefhle und Kognitionen expliziert werden knnen. (c) Springer-Verlag GmbH Deutschland
Keller, Sabine; Page, Dominique; Roten, Yves de; Despland, Jean- Nicolas; Caspar, Franz; Kramer, Ueli	2017	Adaptation of the Motive- Oriented Therapeutic Relationship Scale to group setting in dialectical- behaviour therapy for borderline personality disorder	Journal of Psychotherapy Integration	27	1	47-58	The therapeutic relationship as a process is usually studied in individual therapy, and less in group therapy. One reason for this paucity of research may be the complex methodology necessary to do process research on group therapy. One of the therapeutic approaches using the group as part of the therapy is dialectical behavior therapy (DBT) for borderline personality disorder (BPD). The purpose of the present study is to develop a group version of a process measure that has been successfully used in individual therapy, the Motive-Oriented Therapeutic Relationship (MOTR) scale, based on individualized case conceptualizations using the Plan Analysis approach. To do this, 10 sessions of a DBT skills group therapy were analyzed from a comprehensive dataset within a randomized controlled trial. Included were therapy completers: 3 patients and 2 therapists. The therapists were unaware of MOTR. The results revealed that the adaptation of the MOTR to DBT skills group was feasible. Its adaptation showed differences of the

							therapists in their use of MOTR when comparing the different patients: Therapist presented with higher degrees of MOTR toward 1 patient, compared to another. Overall results suggest that effective therapists in DBT skills training intervene with rather low mean levels of MOTR, and great intrasession variability of MOTR. We conclude that the adaptation of the MOTR-instrument to group therapy is feasible and yields meaningful results. Therefore, this scale may be used in process research in group therapy, in particular when 1 wishes to have an individualized measure of the therapeutic relationship. Keller, Stephanie M.; Tuerk, Peter W.	2016	Evidence-based psychotherapy (EBP) non-initiation among veterans offered an EBP for posttraumatic stress disorder	Psychological Services	13	1	42–48	Current efforts to disseminate evidence-based psychotherapies (EBPs) for posttraumatic stress disorder (PTSD) in Veterans Affairs Medical Centers (VAMCs) have made effective treatment options more available throughout the system. Yet many veterans identified as likely to benefit from such services choose not to utilize them. The evidence base regarding factors that contribute to treatment initiation among those offered EBPs is still in its early stages. The present study investigated clinical presentation, patient demographics, and environment of care factors as potential predictors of EBP treatment initiation among veterans offered such care. The sample consisted of 324 veterans (62% Operation Enduring Freedom [OEF]/Operation Iraqi Freedom [OIF]; 77% male; age M = 42.95, SD = 12.57 years), who attended an intake evaluation at a VAMC outpatient PTSD Clinical Team, were diagnosed with PTSD, and offered a course of EBP. Overall, 72% of veterans (n = 232) who were offered an EBP initiated such treatment, and 28% of veterans (n = 92) did not initiate treatment. Veterans who initiated

							<p>treatment were significantly older. Treatment initiation did not significantly differ by ethnicity, gender, or baseline PTSD severity. Significantly more veterans referred from mental health clinics initiated treatment than did veterans referred from primary care. This study examined treatment initiation among veterans who were offered EBP for PTSD. Rates of initiation differed across subgroups of veterans. Clinically, this suggests the need to tailor outreach efforts to younger veterans, OEF/OIF veterans, and veterans referred from primary care, and potentially including programming and education aimed at primary care referrers, to increase help-seeking. (PsycINFO Database Record (c) 2016 APA, all rights reserved)</p>
<p>Kellett, Stephen; Oxborough, Pippa; Gaskell, Chris</p>	<p>2021</p>	<p>Treatment of compulsive buying disorder: comparing the effectiveness of cognitive behavioural therapy with person-centred experiential counselling</p>	<p>Behavioural and cognitive psychotherapy</p>	<p>49</p>	<p>3</p>	<p>370–384</p>	<p>BACKGROUND: Outcome studies of the treatment of compulsive buying disorder (CBD) have rarely compared the effectiveness of differing active treatments. AIMS: This study sought to compare the effectiveness of cognitive behavioural therapy (CBT) and person-centred experiential therapy (PCE) in a cross-over design. METHOD: This was an ABC single case experimental design with extended follow-up with a female patient meeting diagnostic criteria for CBD. Ideographic CBD outcomes were intensively measured over a continuous 350-day time series. Following a 1-month baseline assessment phase (A; 28 days; three sessions), CBT was delivered via 13 out-patient sessions (B: 160 days) and then PCE was delivered via six out-patient sessions (C: 63 days). There was a 99-day follow-up period. RESULTS: Frequency and duration of compulsive buying episodes decreased during active treatment. CBT and PCE were both highly effective compared with baseline for reducing shopping obsessions, excitement about shopping,</p>

						<p>compulsion to shop and improving self-esteem. When the PCE and CBT treatment phases were compared against each other, few differences were apparent in terms of outcome. There was no evidence of any relapse over the follow-up period. A reliable and clinically significant change on the primary nomothetic measure (i.e. Compulsive Buying Scale) was retained over time. CONCLUSIONS: The study suggests that both CBT and PCE can be effective for CBD. Methodological limitations and suggestions for future CBD outcome research are discussed.</p>
<p>Kelly, Megan M.; Reilly, Erin D.; Ameral, Victoria; Richter, Stephanie; Fukuda, Seiya</p>	<p>2022</p>	<p>A Randomized Pilot Study of Acceptance and Commitment Therapy to Improve Social Support for Veterans with PTSD</p>	<p>Journal of clinical medicine</p>	<p>11</p>	<p>12</p>	<p>Veterans with PTSD often have substantial interpersonal difficulties and low levels of social support, which puts them at increased risk of mortality, but few treatments address global social impairment for veterans with PTSD. This study is a pilot randomized trial of Acceptance and Commitment Therapy to Improve Social Support for Veterans with PTSD (ACT-SS), a psychotherapy that targets social avoidance and eroded social relationships, compared to Person-Centered Therapy (PCT), a non-directive psychotherapy. Participants were randomized to twelve sessions of either ACT-SS (n = 21) or PCT (n = 19). The results showed that veterans with PTSD had high ratings of satisfaction for both treatments. Contrary to the PCT group, participants in the ACT-SS group showed a significant improvement in the quality of social relationships, engagement in social and leisure activities, and PTSD symptoms from the baseline assessment to the end of treatment and a three-month follow-up. Veterans in the ACT-SS group, but not the PCT group, also showed significant improvements in mindfulness and valued living and a reduction in experiential avoidance from baseline to the end of treatment, with sustained</p>

							improvements in valued living at the three-month follow-up. Overall, the present study demonstrated the feasibility, acceptability, and positive preliminary outcomes of ACT-SS for veterans with PTSD.
Kemper, Johannes	2016	Geschichte der Selbsterfahrung aus der Sicht eines Zeitgenossen					berlegungen zum Thema "Geschichte der Selbsterfahrung" werden angestellt. Nach einleitenden Hinweisen zu den Begriffen Selbst und Selbstbild wird unter anderem eingegangen auf die Ursprünge der psychoanalytischen Kur, die Anfänge der Erweiterung der Erkenntnisse der Einzeltherapie auf die Gruppensituation, auf die Einführung der Bedeutung des Beziehungsaspekts zwischen Arzt und Patient durch M. Balint und dessen Konzept der patientenbezogenen Selbsterfahrung des Arztes, auf die Encounter-Gruppen, die im Kontext der Studentenbewegung in den USA entstanden sind, auf gesprächstherapeutische Interventionen im Selbsterfahrungsbereich als Therapie für Gesunde (C. Rogers), auf die Entstehung körperbezogener Selbsterfahrungsgruppen, auf den Einzug der Selbsterfahrungsgruppen in die Hochschulen, auf die Anfänge verhaltenstherapeutischer Gruppen in den 1970-er Jahren, auf psychodynamische Selbsterfahrungsgruppen und deren Wirksamkeit. Es wird für wahrscheinlich gehalten, dass sich die Systemtheorie als hilfreich dabei erweisen könnte, verstärkt den Gedanken der Gruppenfähigkeit und der Beziehungsfähigkeit der Menschen der unendlichen Aufgabe der Selbstverwirklichung zur Seite zu stellen.
Keogh, Daragh; Timulak, Ladislav	2023	"It's wrong to relax, you have to be on the go, go, go, all the time":	Couns and Psychother Res (Counselling and	23	4	1015–1027	

		Emotional transformation in a case of emotion-focused therapy for generalised anxiety disorder	Psychotherapy Research)				
Kern, Ernst	2023	Personzentrierte Körperpsychotherapie bei Trauma	Gesprächspsychotherapie und Personzentrierte Beratung			7-12	Traumatische Erfahrungen können zu existenziellen Erschütterungen führen. Als Folge verliert die Person oft den positiven Bezug zu sich selbst und zu ihrer Umgebung. Sie flüchtet sich in eine Gefühlsvermeidung, die Gefahr, dass die erlebens- und Schutzmechanismen chronifizieren und zu eigenen Problemfeldern führen, ist groß. Personzentrierte Zugänge haben ein besonderes Potenzial, der Person in diesen tiefgehenden Verunsicherungen zu begegnen und blockierte Entwicklungsprozesse wieder anzustoßen. Die Orientierung auf den Körper und sein ganzheitlicher Einbezug sind dabei ganz besonders hilfreich, um das Erleben wieder zu öffnen und die Wiederaneignung von Lebendigkeit zu unterstützen.
Kern, Ernst	2018	Körperbezug					Die Personzentrierte Psychotherapie hatte schon immer den Menschen als Ganzes zum Gegenstand, zu dem selbstverständlich auch der Körper gehört. Aufgrund der philosophischen Wurzeln, insbesondere in der Phänomenologie und Anthropologie, werden dabei der erlebende und der erlebte Körper als zentraler Ausgangspunkt genommen. (c) Springer-Verlag GmbH Deutschland
Kernberg, Otto F.	2016	New developments in transference focused psychotherapy	The International journal of psycho-analysis	97	2	385-407	This paper will summarize recent clinical developments in the treatment of borderline patients at the Personality Disorders Institute at Cornell. The experiences under review will include the careful, ongoing monitoring of developments in the patient's life outside the sessions,

							and their consideration in diagnosing affective dominance during the hours. Other issues include the discussion of a 'second chance' approach to contract violations; the assessment and concern with the patient's assumption of responsibility for himself; the contradictions between actual behavior patterns and life goals, and between personality potentials and present functioning; the technical implications of particular constellations of regressive narcissistic features; drug dependence and antisocial behavior; and life goals and treatment goals.
Kerr, Anna M.; Biechler, Merri; Kachmar, Ulyana; Palocko, Bradley; Shaub, Tracy	2020	Confessions of a Reluctant Caregiver Palliative Educational Program: Using Readers' Theater to Teach End-of-Life Communication in Undergraduate Medical Education	Health communication	35	2	192-200	End-of-life care can be stressful for patients, caregivers, and providers. Caregivers often experience high levels of burden from caregiving duties such as performing medical tasks, communicating with providers, and making decisions. Similarly, many physicians feel unprepared to provide end-of-life care or communicate with patients and families about sensitive issues associated with death and dying. Physicians often attribute their lack of preparation to inadequate training in medical school. Previous research suggests that drama-based learning opportunities are valuable supplements to existing end-of-life curricula. The current study evaluates the success of the Confessions of a Reluctant Caregiver Palliative Educational Program - a drama-based educational program that depicts patient and caregiver experiences. A total of 477 osteopathic medical students participated in the program, which includes viewing a play, engaging in a facilitated post-performance talkback session, and completing an evaluation survey. The results suggest the program is a valuable learning experience that is positively associated with important facets of experiential learning using narratives such as perceived

							realism, increased reflection, strong emotions, and increased comfort with difficult behaviors. The program offers a safe environment for medical students to identify, understand, and process the sensitive and complex issues associated with end-of-life care. Moreover, the play offers insight into the often-overlooked experiences of family caregivers who are at risk of experiencing high caregiver burden while managing health-related communication and decision-making.
Kershaw, Helen; Farrell, Lara J.; Donovan, Caroline; Ollendick, Thomas	2017	Cognitive Behavioral Therapy in a One-Session Treatment for a Preschooler With Specific Phobias	Journal of cognitive psychotherapy	31	1	7-22	Anxiety disorders among preschool-aged children are as prevalent as in older children, yet younger children are even less likely to receive treatment for these frequently impairing childhood disorders (Egger & Angold, 2006). Specific phobias (SPs) are often the earliest form of anxiety to onset, affect 2.3% of preschoolers (Egger & Angold, 2006), and tend to be stable from 3 years of age to at least 6 years of age (Bufferd, Dougherty, Carlson, Rose, & Klein, 2012). Recently, our group developed and piloted a modified intensive one-session treatment (OST) incorporating play therapy for preschoolers with SP (Farrell, Kershaw, & Ollendick, in press). Given that highly fearful young children may find concentrated, rapid exposure therapy highly confronting, we integrated play therapy into the commencement of this treatment to (a) assist with rapid rapport building with the therapist and (b) enhance the child's motivation through engaging them with play. An initial, controlled, baseline case series (N = 4) provided preliminary evidence of the feasibility, acceptability, and effectiveness of this innovative one-session (3 hours) therapy-POP! Pre-schoolers Overcoming Phobias (POP; Farrell et al., in press). The approach combines child-centered, nondirective play therapy (during Hour 1) and empirically supported OST

							(during Hours 2 and 3), with 4-year-old preschool children with clinical SPs of dogs. This article presents a case description of POP, describing the assessment approach, cognitive-behavioral case formulation, and intensive treatment of a 4-year-old girl who presented with a severe SP of dogs, along with various other comorbid SPs.
Keshen, Aaron; Bartel, Sara; Frank, Guido K. W.; Svedlund, Nils Erik; Nunes, Abraham; Dixon, Laura; Ali, Sarrah I.; Kaplan, Allan S.; Hay, Phillipa; Touyz, Stephan; Romo-Nava, Francisco; McElroy, Susan L.	2022	The potential role of stimulants in treating eating disorders	The International journal of eating disorders	55	3	318–331	<p>BACKGROUND Many individuals with eating disorders remain symptomatic after a course of psychotherapy and pharmacotherapy; therefore, the development of innovative treatments is essential.</p> <p>METHOD To learn more about the current evidence for treating eating disorders with stimulants, we searched for original articles and reviews published up to April 29, 2021 in PubMed and MEDLINE using the following search terms: eating disorders, anorexia, bulimia, binge eating, stimulants, amphetamine, lisdexamfetamine, methylphenidate, and phentermine.</p> <p>RESULTS We propose that stimulant medications represent a novel avenue for future research based on the following: (a) the relationship between eating disorders and attention deficit/hyperactivity disorder (ADHD); (b) a neurobiological rationale; and (c) the current (but limited) evidence for stimulants as treatments for some eating disorders. Despite the possible benefits of such medications, there are also risks to consider such as medication misuse, adverse cardiovascular events, and reduction of appetite and pathological weight loss. With those risks in mind, we propose several directions for future research including: (a) randomized controlled trials to study stimulant treatment in those with bulimia</p>

							<p>nervosa (with guidance on strategies to mitigate risk); (b) examining stimulant treatment in conjunction with psychotherapy; (c) investigating the impact of stimulants on "loss of control" eating in youth with ADHD; and (d) exploring relevant neurobiological mechanisms. We also propose specific directions for exploring mediators and moderators in future clinical trials.</p> <p>DISCUSSION</p> <p>Although this line of investigation may be viewed as controversial by some in the field, we believe that the topic warrants careful consideration for future research.</p>
Kessler, Dorothy; Walker, Ian; Sauvé-Schenk, Katrine; Egan, Mary	2019	Goal setting dynamics that facilitate or impede a client-centered approach	Scandinavian journal of occupational therapy	26	5	315–324	<p>BACKGROUND: Client-centred goal setting is central to the process of enabling occupation. Yet, there are multiple barriers to incorporating client-centred goal setting in practice. We sought to determine what might facilitate or impede the formation of client-centred goals in a context highly supportive of client-centred goal setting</p> <p>Methods: We used conversational analysis to examine goal-setting conversations that took place during a pilot trial of Occupational Performance Coaching for stroke survivors. Twelve goal-setting sessions were purposively selected, transcribed, and analyzed according to conventions for conversation analysis.</p> <p>RESULTS: Two main types of interactions were observed: introductory actions and goal selection actions. Introductory actions set the context for goal setting and involved sharing information and seeking clarification related to goal requirements and clients' occupational performance competencies. Goal selection actions were a series of interactions whereby the goals were explored, endorsed or dropped.</p> <p>CONCLUSION: Client-centred occupational performance goals may be facilitated through placing goal-setting in the context of life changes</p>

							and lifelong development of goals, and through listening to clients' stories. Therapists may improve consistency in adoption of client-suggested goals through clarifying meaning attached to goals and being attuned to power dynamics and underlying values and beliefs around risk and goal attainability.
Kfer-Schmid, Gerald; Kurl, Neena; Keil, Sylvia; Korunka, Christian; Topaloglou, Helga M.	2022	Forschung in der Personzentrierte n und Experienziellen Psychotherapie 2008-2019. Ein narrativer Review - Teil 2	Person	26	1	5–20	File, Hutterer, Keil, Korunka und Macke-Bruck beschäftigten sich in einem 2008 verffentlichten Artikel vorrangig mit publizierten Wirksamkeitsstudien ber Klienten-/Personzentrierte und Experienzielle Psychotherapien aus den Jahren 1991 bis 2008. Aktuell wurde systematisch der Frage nachgegangen, welche Entwicklungen es in den elf Folgejahren gegeben hat. 343 in facheinschlgigen Zeitschriften publizierte Forschungsarbeiten wurden ausgewertet. Der erste narrative Review setzte sich mit der Forschung von am personzentrierten Ansatz orientierten Psychotherapien breiter auseinander. Dieser zweite Teil befasst sich mit der Ausbildungsforschung, den Strungsbildern in der personzentrierten Forschung und mit dem Bereich der Kinder-, Spiel- und Jugendlichenpsychotherapie.
Khan, Fahad; Keshavarzi, Hooman; Ahmad, Mahnoor; Ashai, Shereen; Sanders, Peter	2023	Application of Traditional Islamically Integrated Psychotherapy (TIIP) and its clinical outcome on psychological distress among American Muslims in	Spirituality in Clinical Practice		23 26- 45 19(Ele ctr oni c), 23 26- 45 00(No Paginatio n Specified -No Paginatio n Specified		Although individuals frequently turn to religion and spirituality in times of crises and other mental health concerns (Vieten & Lukoff, 2022; Yamada et al., 2020), limited research explores its utility when purposefully integrated into mental health treatment, especially in Muslim populations. While there is evidence for the clinical efficacy of Islamic adaptations of cognitive and rational therapies for Muslim patients, there are very few clinical outcome studies on inherently Islamic models of psychotherapy (Hook et al., 2010; Smith et al., 2007; Worthington & Sandage, 2001). The present study explored the clinical efficacy of an Islamic model of

		outpatient therapy			Print)	<p>psychotherapy, known as Traditional Islamically Integrated Psychotherapy (TIIP; Keshavarzi et al., 2020) through a practice-based evidence approach. Five clinicians, trained in the TIIP model, offered services to 107 patients for 420 sessions at an outpatient mental health center tailored to address Muslim mental health concerns. The therapist session checklist indicated that TIIP practitioners not only utilized Islamic spiritual interventions but also integrated cognitive and emotion-focused interventions into the TIIP model of care. The outcomes of the study demonstrated a reduction in clinical distress as measured by Clinically Adaptive Multidimensional Outcome Survey and a reduction in functional distress through clinical outcomes in routine evaluation over time, indicating preliminary evidence for the efficacy of TIIP in application to Muslim patients. Process variables such as session intentions, counseling topics, as well as specific interventions from the TIIP model are presented. (PsycInfo Database Record (c) 2023 APA, all rights reserved)</p>
Khan, Kaleem; Pelletier, Guy		Identity processing styles and quality of life in head and neck cancer	Canadian Journal of Behavioural Science / Revue canadienne des sciences du comportement	53	3	<p>A cancer diagnosis produces important disruptions in a person's life that can lead to a reconsideration of one's roles, values, purposes, and goals. This may threaten one's identity, which can be defined as an implicit self-theory construed using different identity processing styles (IPSs), categorised as informational, normative, and diffuse-avoidant. This study examined IPSs, commitment to identity, and their relationship to psychosocial outcomes in head and neck cancer (HNC) survivors. Sixty patients (age: M = 57.4, SD = 9.9) were recruited from an HNC outpatient clinic. Participants were at least 1 year posttreatment, on medical follow up, and free of recurrence. All participants completed</p>

							<p>questionnaires assessing IPS, quality of life (QoL), anxiety and depression, positive and negative perceptions of illness impact, and body image concerns. Correlational analyses showed that commitment to identity was significantly related to higher QoL, illness impact, and anxiety. A normative IPS was related to higher QoL. A diffuse-avoidant IPS was related to a negative perception of illness impact. A bootstrapped multiple regression analysis showed that only the normative IPS was a significant predictor of overall QoL. For this sample of HNC patients, a stronger commitment to normative goals, values, and beliefs contributed to the preservation of identity and to a greater sense of well-being during survivorship. Many forms of psychotherapy include a focus on various aspects of identity, some more directly than others. We discuss how such therapies may be applied to improve psychosocial outcomes in HNC patients. (PsycInfo Database Record (c) 2021 APA, all rights reserved)</p>
<p>Khayyat-Abuaita, Ula; Paivio, Sandra; Pascual-Leone, Antonio; Harrington, Shawn</p>	2019	<p>Emotional processing of trauma narratives is a predictor of outcome in emotion-focused therapy for complex trauma</p>	<p>Psychotherapy (Chicago, Ill.)</p>	56	4	526–536	<p>This study tested a model of emotional processes over the course of emotion-focused therapy for trauma. The model of emotional processing (Pascual-Leone & Greenberg, 2007) proposes a sequential order of shifting from "early expressions of distress" to "primary adaptive emotion" that aid in adaptive functioning. Thirty-eight participants were taken from a randomized clinical trial to examine in-session process from video recordings of treatment. The sample had an average age (M = 44.3 years) and the majority was female (55.3%) and of European descent (89.5%). The Classification of Affective Meaning States was used to examine changes in emotional processes during trauma narratives in both early and late sessions. Processes were related to</p>

							<p>treatment outcome as measured by the Impact of Event Scale and the Resolution Scale. Sessions later in treatment showed a higher frequency of primary adaptive emotions compared with early sessions ($p < .001$, $r = .76$). Primary adaptive emotions were also more frequent in good-outcome cases ($p = .017$). Using emotional processes as predictors correctly classified 67% of poor-outcome cases and 80% of good-outcome cases. Increases in primary adaptive emotions from early to late treatment sessions more than doubled the odds (2.2) of having a good treatment outcome. The order of emotion was concordant with the sequential model in early sessions and partially concordant in late sessions. Findings have implications for guiding therapeutic process in a productive manner that leads to trauma recovery. Changes in discrete emotions were related to good treatment outcome. (PsycINFO Database Record (c) 2019 APA, all rights reserved).</p>
Kiely, Laura; Touyz, Stephen; Conti, Janet; Hay, Phillipa	2022	Conceptualising specialist supportive clinical management (SSCM): current evidence and future directions	Journal of eating disorders	10	1	32	<p>BACKGROUND: Current evidence-based treatments for adult anorexia nervosa (AN) have limitations, with high attrition, very poor outcomes for 20% of people, and no clearly superior manualised therapy for adults with AN. Specialist Supportive Clinical Management (SSCM) was designed as a control treatment but has evolved as a valid first line treatment. The present paper aims to provide an overview of the evidence base for SSCM and a pedagogical reconceptualization with expansion by theoretical integration (TI). BODY: A secondary meta-analysis endorses SSCM as a promising treatment. This paper positions SSCM as a manualised therapy for adult AN with six unique features, namely (1) a philosophy which is person-centred, non-prescriptive, and informed by the person's strengths and values, (2) a focus on the</p>

						<p>person through inclusion of supportive psychotherapy and problem (clinical management), within target symptoms as defined in relation to AN, (3) a flexible and responsive therapy that could be delivered by a variety of clinicians with experience treating AN (4) a commitment to reversing starvation through a directional approach and a defined yet flexible stance on dietetic intervention (5) a commitment to the therapeutic relationship within all three phases of treatment, and (6) a therapy 'uncluttered' by specific mandates. In addition, this paper positions SSCM as a treatment that may be strengthened by other modalities and may also be adapted to the treatment of other eating disorders (ED), not just AN. The level of therapist sophistication to deliver upon the supportive psychotherapy component is explored and future directions are offered. CONCLUSION: SSCM is a unique and valid first line treatment for AN and would benefit from further expansion in line with emerging understandings of AN to strengthen it as a treatment. Speculation on aspects of potency would benefit from further testing. The proposed re-conceptualisation of SSCM in the context of its evidence may strengthen it as a treatment overall, position it as adaptable for treatment of other eating disorders and make it more accessible to clinicians.</p>
<p>Kılınç, Stephanie; Campbell, Carol; Guy, Alison; van Wersch, Anna</p>	<p>2020</p>	<p>Negotiating the boundaries of the medical model: Experiences of people with epilepsy</p>	<p>Epilepsy & behavior : E&B</p>	<p>102</p>	<p>106674</p>	<p>People with epilepsy (PWE) continually report dissatisfaction with the support they receive, particularly in regard to their psychological wellbeing. With its focus on optimal seizure control, epilepsy treatment is entrenched in the medical model of illness, despite growing evidence of the broader psychosocial impact of the condition. This study aimed to explore how PWE experience healthcare in the context of their lives.</p>

							<p>Semistructured interviews were conducted with thirty-nine adults with epilepsy from across the UK. An adapted version of interpretative phenomenological analysis (IPA) was conducted, and three superordinate themes were identified. Firstly, "negotiating the space between health and illness" identified how participants rejected the illness identity and struggled with a treatment regime, which reminded them of the longevity of their condition. Secondly, "tensions in adopting a biomedical perspective" considered how medical professionals overlooked the negative side effects medication had on participants' lives, in favor of optimal seizure control. Thirdly, "the need for broader support" highlighted the additional psychosocial support PWE require. The findings indicate the need to incorporate person-centered, psychological services within the care pathway for PWE, as well as training for health professionals to recognize the broader impact of epilepsy beyond seizure management.</p>
<p>Kilmer, Elizabeth D.; Villarreal, Cesar; Janis, Beth M.; Callahan, Jennifer L.; Ruggero, Camilo J.; Kilmer, Jared N.; Love, Patrick K.; Cox, Randall J.</p>	2019	Differential early termination is tied to client race/ethnicity status	Practice Innovations	4	2		<p>A significant innovation in the training of doctoral level professional psychologists, attention to diversity, was implemented nearly 3 decades ago and swept across all accredited programs. Regardless of training model, degree type, or theoretical orientation, attention to diversity became a requirement for program accreditation with the intention of fostering important competencies in the emerging workforce who would be serving an increasingly diverse population during their professional careers. However, to date, whether that is what occurred has not been examined. The current study used archival data to examine the association between client racial/ethnic minority (REM) status and early termination from adult individual psychotherapy (N = 638). Multilevel</p>

						<p>modeling analyses (MLM) revealed that REM clients were more likely to terminate treatment after 1 session than non-REM clients. However, REM status did not account for the total number of sessions attended, nor was it a significant predictor of symptom change during treatment. The findings suggest that training focused specifically on first session competencies, such as treatment engagement, with REM clients is strongly needed. More broadly, the findings underscore the importance of examining innovations following implementation to determine whether the intended effects are observed or if refinements may be needed. <p>King, Brittany R.; Boswell, James F.; Schwartzman, Carly M.; Lehrbach, Kyler; Castonguay, Louis G.; Newman, Michelle G.</p>	2020	<p>Use of common and unique techniques in the early treatment phase for cognitive-behavioral, interpersonal/emotional, and supportive listening interventions for generalized anxiety disorder</p>	Psychotherapy	57	3	<p>Psychotherapy research often compares specific treatments to control conditions to establish efficacy of the specified treatment. Research has typically evaluated common factor elements (e.g., credibility, expectancy) in treatments only after the first or second session, largely as a manipulation check and under the assumption that such factors are static. This study observed therapist common factor and model-specific interventions in three treatment approaches from a randomized control trial for generalized anxiety disorder across the entire early phase of treatment (i.e., first five sessions). The parent randomized control trial compared two treatment conditions, using an additive design where patients were randomized to receive either interpersonal/emotional processing interventions or supportive listening after receiving a session of cognitive-behavioral therapy. The first five video-recorded sessions of N = 40 randomly sampled participants were observationally coded with a multidimensional intervention measure, with subscales</p>

						reflecting diverse theoretical orientations and common factors. Multilevel modeling was used to examine intervention use and investigate differences between treatment conditions and segments. Among the results, common factor interventions were rated as significantly more typical in cognitive-behavioral therapy compared with supportive listening. The pattern of intervention use of other subscales was generally consistent with the orientation of the respective protocols. In the early phase of treatment, supportive listening conditions do not appear to function as common factor controls in the manner that many might assume. Common factors are potentially enhanced in bona fide treatments that include a more detailed, specific rationale and clear and cohesive techniques and goals. King, Catherine; Goldstein, Elena; Crits-Christoph, Paul; Connolly Gibbons, Mary Beth		The association between medical comorbidity and psychotherapy processes and outcomes for major depressive disorder in a community mental health setting	Psychotherapy	59	2	Many individuals seeking mental health services for depression often suffer from a comorbid medical condition. The goal of the present study was to assess the presence of medical comorbidity in a community mental health center setting that primarily serves a Medicare and Medicaid population, characterize the types of comorbid medical conditions experienced in this setting, and explore the association between medical conditions on the alliance, attrition from services, and outcome. Medical diagnoses were collected from patient charts and structured clinical interviews from 353 participants who had a baseline assessment as part of a comparative effectiveness study of cognitive and dynamic therapies for major depressive disorder. We calculated the Charlson Comorbidity Index and the number of total medical diagnoses for each patient. Results from this study revealed that a high percentage of patients in this

							setting experienced a comorbid medical condition. No significant associations were found between the number of medical conditions or the Charlson Comorbidity Index and the alliance. No significant relationship was found between the number of medical conditions or the Charlson Comorbidity Index and early attrition from treatment or treatment outcome. However, exploratory analyses found that presence of a nervous system disorder was associated with relatively poorer treatment outcomes after initial engagement. Implications of these findings are discussed. Treatments for major depressive disorder may benefit from addressing the impact of medical disorders on physical functioning. King, Gillian	2017	The Role of the Therapist in Therapeutic Change: How Knowledge From Mental Health Can Inform Pediatric Rehabilitation	Physical & occupational therapy in pediatrics	37	2	121-138	The therapist is a neglected and poorly understood variable in pediatric rehabilitation. Much more attention has been paid to the role of intervention on client change than the role of therapist-related variables. This article synthesizes what is known in the adult and child mental health literature about the role of the therapist, and integrates this with work in pediatric rehabilitation. The article reviews the mental health literature on the therapist as a random variable associated with client outcomes (role of the therapist alone) and the role of three other therapist-related constructs: the therapist-client relationship (therapist and client), treatment implementation (therapist and intervention), and therapy process (therapist, client, and intervention considered holistically). Implications for clinical practice in pediatric rehabilitation include recognition of change as a multi-determined phenomenon involving common therapist-related factors, the therapist's role in creating facilitative conditions for change (through supportive relationships,

							positive expectancies, and mastery and learning experiences), and the importance of training in collaborative partnership skills. A contextual approach to therapeutic change is advocated, in which psychosocial factors and mechanisms are acknowledged, the therapist is seen as crucial, and the intervention process is seen as the context or vehicle through which changes occur.
Kingreen, Tilman	2017	Coaching in der Kirche	Gesprächspsychotherapie und Personenzentrierte Beratung	48	4	189–191	Das Potential personenzentrierten Coachings in der Kirche wird beleuchtet. Vor dem Hintergrund einer siebenjährigen Coachingpraxis für evangelische PastorInnen im Rahmen der "Arbeitsstelle für Personalberatung und Personalentwicklung" wird die Wirkweise von Coaching in einer evangelischen Kirche betrachtet und seine Rückwirkung auf das Verständnis von Coaching im Beruf dargestellt. Dabei wird auf Sinnhorizonte, persönliche Potentiale, Dialogrume, Kongruenz und Organisationskultur eingegangen. Auch für andere Institutionen wird der besondere Nutzen dieses Beratungsformats dabei skizziert, in Veränderungsprozessen bestehende Dialogrume um eine elaborierte und fundierte Selbstaussagekompetenz der Mitarbeitenden zu erweitern.
Kinigadner, Sonja	2018	Sexuelle Strungen					Sexualität nimmt im Leben der allermeisten Menschen einen zentralen Stellenwert ein und ist zumeist mit Lust, Begehren, Ekstase und Befriedigung verbunden. Gleichwohl kann das sexuelle Erleben gestört sein. In der personenzentrierten Literatur ist dem Thema Sexualität im Allgemeinen und den sexuellen Strungen im Besonderen bislang nur wenig Aufmerksamkeit geschenkt worden. Sexualität kann nach personenzentriertem Verständnis als ein Potenzial des Organismus betrachtet werden, wobei aber in der personenzentrierten Theoriebildung keine spezielle Konzeptualisierung von Sexualität vorliegt. Die Darstellung

							und Diskussion psychotherapeutischer Praxis mit Personen mit sexuellen Strungen ist aus personzentrierter Sicht als sehr sprich zu erachten. Die nachfolgenden Ausfhrungen sollten dazu beitragen, diesen Mangel ein wenig zu verringern. (c) Springer-Verlag GmbH Deutschland
Kinnunen, Sanna M.; Puolakanaho, Anne; Tolvanen, Asko; Mäkikangas, Anne; Lappalainen, Raimo	2019	Does mindfulness-, acceptance-, and value-based intervention alleviate burnout?—A person-centered approach	International Journal of Stress Management		15 73- 34 24(Ele ctr oni c), 10 72- 52 45(Pri nt)	89–101	This study investigated individual differences in changes in burnout symptoms during a brief mindfulness-, acceptance-, and value-based intervention. It also studied whether the changes in burnout were simultaneous with the changes in mindfulness skills. The role of practices and learning experiences in these changes were investigated. The participants were employees of various occupations (n = 105, 80% women, Mage = 48 years). Latent profile analysis was used to investigate the associations between burnout and mindfulness skills during the intervention and a 4-month follow-up period. Six distinct profiles were found that differed in levels and changes of both burnout and mindfulness skills. Burnout was reduced and mindfulness skills increased with large effect sizes in three of the profiles (47.4% of the participants). Two profiles (31.1%) presented smaller changes in burnout but had significant increases in mindfulness skills. One profile (11.5%) did not benefit from the intervention. The obtained profiles were compared on practice quantity and frequency, practice continuation, and learning experiences. There were no differences between the profiles in the practice quantity or frequency during the intervention. However, the profiles with the most beneficial changes showed higher learning during the intervention and continued to practice more often after the intervention. These findings show that there are

							considerable differences in the responses to a brief mindfulness-, acceptance-, and value-based intervention. The investigated intervention turned out to be effective in alleviating burnout symptoms, even when the initial burnout was high. Attention should be devoted to enhancing learning and practice continuation to improve intervention outcomes. (PsycINFO Database Record (c) 2019 APA, all rights reserved)
Kip, Kevin E.; Berumen, Jessica; Zeidan, Amina R.; Hernandez, Diego F.; Finnegan, Alan P.	2019	The emergence of accelerated resolution therapy for treatment of post-traumatic stress disorder: A review and new subgroup analyses	Couns and Psychother Res (Counselling and Psychotherapy Research)	19	2	117-129	Abstract Introduction Post-traumatic stress disorder (PTSD) is a chronic, disabling psychiatric disorder prevalent among civilian and military personnel in the United States (US) and United Kingdom (UK). Current trauma-focused psychotherapies may place high emotional demands and lengthy treatment commitment that may hinder successful treatment completion for some patients. Accelerated resolution therapy (ART) is an emerging trauma-focused psychotherapy that is briefer than most current treatments. Materials and Methods This review describes the ART clinical protocol and theoretical underpinnings, its relationship to current treatments and formal established treatment guidelines and empirical research data. Also presented are new subgroup data for the use of ART among clients with PTSD and concomitant traumatic brain injury (TBI), and among US Special Operations Forces (SOF) personnel with extensive combat-related trauma exposure. Treatment response was defined as ≥ 10 -point reduction on the 17-item PCL-M (PTSD Checklist). Results In subgroup analyses, mean treatment with ART consisted of approximately four sessions. Among 202 US service members/veterans, intention-to-treat response rates (assuming no response for non-completers) by TBI status were as follows: no TBI (58.1%, n = 105), mild TBI (60.4%,

							n = 48), moderate/severe TBI (46.9%, n = 49). Among 141 US service members/veterans, intention-to-treat response rates by SOF status were as follows: non-SOF (54.3%, n = 116), SOF (60.0%, n = 25). Conclusion The ART protocol aligns closely with established first-line trauma-focused psychotherapies and clinical guidelines. It appears to provide frequent clinical relief of symptoms of PTSD in an average of four sessions among military personnel with challenging clinical presentations, including concomitant TBI and extensive operational combat-related trauma.
Kirby, Jennifer S.; Fischer, Melanie S.; Raney, Thomas J.; Baucom, Donald H.; Bulik, Cynthia M.	2016	Couple-based interventions in the treatment of adult anorexia nervosa: A brief case example of UCAN	Psychotherapy	53	2	241–250	Adult anorexia nervosa (AN) is a serious and often fatal illness that significantly erodes quality of life for both the patient and loved ones. Treatment of adults with AN has focused largely on individual therapy, with recent findings suggesting that improvement is limited and dropout rates are high. In an effort to improve treatment response, we developed a couple-based intervention, Uniting Couples in the treatment of Anorexia Nervosa (UCAN) as an adjunct treatment to standard multidisciplinary care. UCAN leverages the support of a partner and the relationship in treatment by decreasing avoidance around AN, teaching the couple how to effectively address the eating disorder, and helping to foster a more satisfying relationship. This paper presents a case study of a couple who completed UCAN, “Laura and Steve,” including their experiences in treatment and outcome measures at pretest, posttest, and 3-month follow-up. Laura showed clinically significant change on the Restraint subscale of the Eating Disorders Examination at follow-up, and both partners showed clinically significant improvements in relationship satisfaction, as well as on self-reported and observed communication. Both partners reported very

							high satisfaction with the treatment. A discussion of therapists' experiences in delivering UCAN is provided, including common challenges for therapists with primarily a couple therapy or an individual CBT for eating disorders background, as well as important factors for therapists to consider in order to optimally leverage the benefits of including partners in treatment for AN. Dabei wird auf folgende Punkte eingegangen: (1) Kernaspekte dieser beiden Therapieanstze, (2) therapeutische Beziehung und Allianzbildung, (3) Klrunge bzw. Erschlieung sowie Bearbeitung und Vernderung problematischer Schemata. Abschlieend werden berlegungen zur Mglichkeit einer Integration dieser beiden Anstze angestellt.</p>
Kivari, Carson A.; Oliffe, John L.; Borgen,	2018	No Man Left Behind: Effectively	American journal of men's health	12	2	241–251	<p>Ex-military men have emerged as a vulnerable subgroup for mental illness amid long-standing trends signaling men's reticence to seek professional help. Less explored</p>

William A.; Westwood, Marvin J.		Engaging Male Military Veterans in Counseling					is how men engage or disengage when they actually do enter helping programs. Contrasting decades of quantitative research pairing masculine ideology with low help seeking (i.e., describing the problem), this article draws on qualitative data to distill factors that help men become engaged and committed to counseling (i.e., identifying solutions). Shared is an evaluation of a treatment program with high success rates and virtually no dropouts-a unique occurrence in men's counseling. Enhanced Critical Incident Technique data suggest that helping men feel competent and free from judgment in the company of down-to-earth peers and genuine practitioners are instrumental in helping men draw benefit from counseling. While appealing to male gender roles may be critical in recruiting men to counseling, men can transition to embrace virtues (i.e., that might be shared by men and women alike) and universal human needs as counseling progresses.
Kivity, Yogev; Levy, Kenneth N.; Kelly, Kristen M.; Clarkin, John F.	2021	In-session reflective functioning in psychotherapie s for borderline personality disorder: The emotion regulatory role of reflective functioning	Journal of consulting and clinical psychology	89	9	751-761	Objective: The capacity for understanding mental states (reflective functioning; RF) is considered essential for self-growth, social learning, and emotion regulation. Impaired RF is thought to play a central role in borderline personality disorder (BPD). We examined whether asking patients to consider mental states in-session has a down-regulatory effect on emotional arousal in treatments for BPD. Method: Early-, middle- and late-phase videotaped sessions from a randomized-controlled trial of transference-focused psychotherapy (TFP; n = 30), dialectical behavior therapy (DBT; n = 29), and supportive psychodynamic therapy (SPT; n = 29) were segmented to therapist and patient talk-turns. Therapist talk-turns were rated as asking patients to consider mental state (bids for RF) or not. Patient talk-turns were rated for RF and

						acoustically encoded for arousal. Results: Bids were twice as common in TFP compared to DBT and SPT. Across treatments, therapist bids for RF predicted better RF, which, in turn, predicted lower emotional arousal. Conclusions: Asking patients to consider mental states has a down-regulatory effect on patients' arousal in psychotherapies for BPD. (PsycInfo Database Record (c) 2022 APA, all rights reserved)
Kizilhan, Jan Ilhan	2016	Handbuch psychische Erkrankungen fr soziale Berufe. Klein-Isberner, Thomas; Wenzel, Katja	2017	Angewandte Erlebnistherapie als komplementre Behandlung bei Sucht- und Psychosomatikpatienten in der Fontane-Klinik					Erfahrungen mit angewandter Erlebnistherapie als komplementrer Behandlung bei stationren Patienten mit Suchterkrankungen und psychosomatischen Strungen werden prsentiert. Dabei wird deutlich gemacht, dass es sich bei erlebnistherapeutischen Bedingungen um herausfordernde Grenzsituationen mit Aufforderungscharakter und hoher emotionaler Beteiligung handelt, die vom Patienten Entscheidungen - meist ohne Rckgriff auf bewhrte Lsungsmuster - verlangen. Grundlagen der erlebnistherapeutischen Arbeit werden skizziert, der Einsatz und die Umsetzung in der Klinik werden geschildert, und Wirkungen, Grenzen und Potenziale dieser Form der Behandlung werden beschrieben.

Kleiven, Gøril Solberg; Hjeltnes, Aslak; Brattland, Heidi; Moltu, Christian	2023	Moments of change: Clients' immediate experiences when sharing emotions in psychotherapy	Psychotherapy research : journal of the Society for Psychotherapy Research			1-13	<p>OBJECTIVE: In-session processing of emotions is important in facilitating psychotherapeutic change. This study explores how clients in active treatment experience inner changes when sharing emotions in psychotherapy sessions. The aim was to retrieve in-depth knowledge about clients' moment-by-moment experiences of change in a naturalistic psychotherapy context. METHOD: Two psychotherapy sessions (session 3 or 4 and session 7 or 8) were videotaped and immediately followed by semi-structured interviews with clients (n = 11) in the format of Interpersonal Process Recall (IPR). Interviews were analysed using thematic analysis. RESULTS: Four themes resulted from analysis: (1) reaching a new clarity about inner struggles; (2) a shift in how I approach and experience my feelings; (3) grieving losses and gaining a more positive understanding of myself; (4) feeling relief and liberation when allowing difficult emotions. CONCLUSION: The resulting themes took into account the importance of the felt quality of change experiences within sessions, which appears to be important in making micro-processes of change salient. Across themes, we found accounts of shifts in awareness and self-compassion, which we discuss as micro-outcomes that clients can ideally be guided to dwell with.</p>
Kletter, Hilit; Matlow, Ryan; Tanovic, Selma; Carrion, Victor	2021	Cue-Centered Therapy for Youth Experiencing Posttraumatic Symptoms	Current treatment options in psychiatry	8	3	125-140	<p>PURPOSE: Few of the existing evidence-based interventions for child trauma exposure were specifically designed to address experiences and outcomes of complex developmental trauma. Stanford's cue-centered therapy (CCT) was designed to address this gap by offering a flexible, integrative, and insight-oriented treatment approach that is grounded in principles of neuroscience, developmental trauma, client empowerment, and allostasis. This article reviews the</p>

						<p>CCT rationale, treatment components, evidence base, and training approach. RECENT FINDINGS: Studies demonstrate promising outcomes indicating CCT effectiveness in reducing child and caregiver posttraumatic stress, and in improving child functioning. Further research, however, is needed to identify which clients are best-suited for CCT (versus other available child trauma treatments) and to identify which components of CCT are most critical for addressing complex developmental trauma. SUMMARY: CCT advances the field of child trauma treatment by offering an intervention approach focused on addressing complex developmental trauma. Positive treatment and training outcomes indicate utility of CCT for clients and clinicians. Innovations in research and training approaches are needed to further dissemination and implementation of CCT and other related child trauma interventions for complex developmental trauma.</p>
<p>Klimas, J.; Fairgrieve, C.; Tobin, H.; Field, C. A.; O'Gorman, C. S.M.; Glynn, L. G.; Keenan, E.; Saunders, J.; Bury, G.; Dunne, C.; et al.</p>	2018	<p>Psychosocial interventions to reduce alcohol consumption in concurrent problem alcohol and illicit drug users</p>	<p>Cochrane Database of Systematic Reviews</p>	<p>12(12):CD009269. doi: 10.1002/14651858.cd009269.pub4</p>	12	<p>Abstract - Background Problem alcohol use is common among people who use illicit drugs (PWID) and is associated with adverse health outcomes. It is also an important factor contributing to a poor prognosis among drug users with hepatitis C virus (HCV) as it impacts on progression to hepatic cirrhosis or opioid overdose in PWID. Objectives To assess the effectiveness of psychosocial interventions to reduce alcohol consumption in PWID (users of opioids and stimulants). Search methods We searched the Cochrane Drugs and Alcohol Group trials register, the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, CINAHL, and PsycINFO, from inception up to August 2017, and the reference lists of eligible articles. We also searched: 1) conference proceedings (online</p>

						<p>archives only) of the Society for the Study of Addiction, International Harm Reduction Association, International Conference on Alcohol Harm Reduction and American Association for the Treatment of Opioid Dependence; and 2) online registers of clinical trials: Current Controlled Trials, ClinicalTrials.gov, Center Watch and the World Health Organization International Clinical Trials Registry Platform. Selection criteria We included randomised controlled trials comparing psychosocial interventions with other psychosocial treatment, or treatment as usual, in adult PWIDs (aged at least 18 years) with concurrent problem alcohol use. Data collection and analysis We used the standard methodological procedures expected by Cochrane. Main results We included seven trials (825 participants). We judged the majority of the trials to have a high or unclear risk of bias. The psychosocial interventions considered in the studies were: cognitive-behavioural coping skills training (one study), twelve-step programme (one study), brief intervention (three studies), motivational interviewing (two studies), and brief motivational interviewing (one study). Two studies were considered in two comparisons. There were no data for the secondary outcome, alcohol-related harm. The results were as follows. Comparison 1: cognitive-behavioural coping skills training versus twelve-step programme (one study, 41 participants) There was no significant difference between groups for either of the primary outcomes (alcohol abstinence assessed with Substance Abuse Calendar and breathalyser at one year: risk ratio (RR) 2.38 (95% confidence interval [CI] 0.10 to 55.06); and retention in treatment, measured at end of treatment: RR 0.89 (95% CI 0.62 to 1.29), or for any of the secondary outcomes reported. The quality of evidence for</p>
--	--	--	--	--	--	--

						<p>the primary outcomes was very low. Comparison 2: brief intervention versus treatment as usual (three studies, 197 participants) There was no significant difference between groups for either of the primary outcomes (alcohol use, measured as scores on the Alcohol Use Disorders Identification Test (AUDIT) or Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) at three months: standardised mean difference (SMD) 0.07 (95% CI -0.24 to 0.37); and retention in treatment, measured at three months: RR 0.94 (95% CI 0.78 to 1.13), or for any of the secondary outcomes reported. The quality of evidence for the primary outcomes was low. Comparison 3: motivational interviewing versus treatment as usual or educational intervention only (three studies, 462 participants) There was no significant difference between groups for either of the primary outcomes (alcohol use, measured as scores on the AUDIT or ASSIST at three months: SMD 0.04 (95% CI -0.29 to 0.37); and retention in treatment, measured at three months: RR 0.93 (95% CI 0.60 to 1.43), or for any of the secondary outcomes reported. The quality of evidence for the primary outcomes was low. Comparison 4: brief motivational intervention (BMI) versus assessment only (one study, 187 participants) More people reduced alcohol use (by seven or more days in the past month, measured at six months) in the BMI group than in the control group (RR 1.67; 95% CI 1.08 to 2.60). There was no difference between groups for the other primary outcome, retention in treatment, measured at end of treatment: RR 0.98 (95% CI 0.94 to 1.02), or for any of the secondary outcomes reported. The quality of evidence for the primary outcomes was moderate. Comparison 5: motivational interviewing (intensive) versus motivational interviewing</p>
--	--	--	--	--	--	--

						<p>(one study, 163 participants) There was no significant difference between groups for either of the primary outcomes (alcohol use, measured using the Addiction Severity Index-alcohol score (ASI) at two months: MD 0.03 (95% CI 0.02 to 0.08); and retention in treatment, measured at end of treatment: RR 17.63 (95% CI 1.03 to 300.48), or for any of the secondary outcomes reported. The quality of evidence for the primary outcomes was low. Authors' conclusions We found low to very low-quality evidence to suggest that there is no difference in effectiveness between different types of psychosocial interventions to reduce alcohol consumption among people who use illicit drugs, and that brief interventions are not superior to assessment-only or to treatment as usual. No firm conclusions can be made because of the paucity of the data and the low quality of the retrieved studies. Plain language summary Which talking therapies work for people who use drugs and also have alcohol problems? Review question We wanted to see whether talking therapies reduce drinking in adult users of illicit drugs (mainly opioids and stimulants). We also wanted to find out whether one type of therapy is more effective than another. Background Drinking alcohol above the low-risk drinking limits can lead to serious alcohol use problems or disorders. Drinking above those limits is common in people who also have problems with other drugs. It worsens their physical and mental health. Talking therapies aim to identify an alcohol problem and motivate an individual to do something about it. Talking therapies can be given by trained doctors, nurses, counsellors, psychologists, etc. Talking therapies may help reduce alcohol use but we wanted to find out if they can help people who also have problems with other drugs. Search</p>
--	--	--	--	--	--	--

						<p>date : the evidence is current to August 2017. Study characteristics We found seven studies that examined five talking therapies among 825 people with drug problems. Cognitive-behavioural coping skills training (CBCST) is a talking therapy that focuses on changing the way people think and act. The twelve-step programme is based on theories from Alcoholics Anonymous and aims to motivate the person to develop a desire to stop using drugs or alcohol. Motivational interviewing (MI) helps people to explore and resolve doubts about changing their behaviour. It can be delivered in group, individual and intensive formats. Brief motivational interviewing (BMI) is a shorter MI that takes 45 minutes to three hours. Brief interventions are based on MI but they take only five to 30 minutes and are often delivered by a non-specialist. Six of the studies were funded by the National Institutes for Health or by the Health Research Board; one study did not report its funding source. Key results We found that the talking therapies led to no differences, or only small differences, for the outcomes assessed. These included abstinence, reduced drinking, and substance use. One study found that there may be no difference between CBCST and the twelve-step programme. Three studies found that there may be no difference between brief intervention and usual treatment. Three studies found that there may be no difference between MI and usual treatment or education only. One study found that BMI is probably better at reducing alcohol use than usual treatment (needle exchange), but found no differences in other outcomes. One study found that intensive MI may be somewhat better than standard MI at reducing severity of alcohol use disorder among women, but not among men and found no differences in other outcomes. It</p>
--	--	--	--	--	--	---

							remains uncertain whether talking therapies reduce alcohol and drug use in people who also have problems with other drugs. High-quality studies are missing and are needed. Quality of evidence The quality of the evidence was moderate for brief and intensive motivational interviewing, but low for brief interventions and standard motivational interviewing, and very low for CBCST versus twelve-step programme.
Klimesch, Anne; Martinez-Pereira, Alejandra; Topf, Cheyenne; Härter, Martin; Scholl, Isabelle; Bravo, Paulina	2023	Conceptualization of patient-centered care in Latin America: A scoping review	Health expectations : an international journal of public participation in health care and health policy	26	5	1820–1831	INTRODUCTION: Patient-centered care (PCC) has been declared as a desirable goal for health care in Latin American countries, but a coherent definition of what exactly PCC entails for clinical practice is missing. This article's aim was to identify how PCC is conceptualized in Latin American countries. METHODS: Scientific databases (MEDLINE, EMBASE, PsycINFO, CINAHL, Scielo, Scopus, Web of Science) and webpages of the ministries of health were searched, and experts were contacted for suggestions of literature. References were included if they contained one of a range of a priori defined keywords related to PCC in the title, were published between 2006 and 2021, and were carried out in or concerned Latin America. Definitions of PCC were extracted from the included articles and analyzed using deductive and inductive coding. Deductive coding was based on the integrative model of patient-centeredness, which unites the definitions of PCC in the international literature (mainly North America and Europe) and proposes 16 dimensions describing PCC. RESULTS: Thirty-two articles were included in the analysis and about half of them were from Brazil. Numerous similarities were found between the integrative model of patient-centeredness and the definitions of PCC given in the selected literature. The dimensions of the integrative

						<p>model of patient-centeredness that were least and most prominent in the literature were physical support and patient information, respectively. A differentiation between PCC and family-centered care (FCC) was observed. Definitions of PCC and FCC as well as their cited references were diverse. CONCLUSION: A considerable overlap between the conceptualization of PCC in Latin America and the integrative model of patient-centeredness has been identified. However, there are substantial differences between countries in Latin America regarding the emphasis of research on PCC versus FCC and diverse conceptualizations of PCC and FCC exist. PATIENT CONTRIBUTION: This scoping review takes the patient's perspective based on the integrative model of patient-centeredness. Due to the study being a review, no patients, neither caregivers, nor members of the public, were involved.</p>
<p>Kline, Alexander C.; McCabe, Cameron T.; Campbell, Justin S.; Walter, Kristen H.</p>		<p>Residual posttraumatic stress disorder and depression symptoms following a residential posttraumatic stress disorder treatment program for U.S. active duty service members</p>	<p>Psychological Trauma: Theory, Research, Practice, and Policy</p>			<p>Objective: Even after the most effective posttraumatic stress disorder (PTSD) treatments, symptoms often persist. Understanding residual symptoms is particularly relevant in military populations, who may be less responsive to PTSD interventions. Method: The sample consisted of 282 male service members who engaged in a residential PTSD treatment program at a military treatment facility that provided evidence-based PTSD psychotherapies and adjunctive interventions. PTSD and depression symptoms were assessed before and after treatment and weekly during treatment via the PTSD Checklist-Military Version and Patient Health Questionnaire-8. Logistic regression with Hochberg's step-up procedure compared the likelihood of individual residual symptoms between service members who did (n = 92, 32.6%) and did not (n = 190, 67.4%) experience</p>

							<p>clinically significant PTSD change (≥ 10-point PTSD Checklist-Military Version reduction). Results: Not achieving clinically significant PTSD change was associated with greater odds of nearly all residual symptoms (OR = 2.03–6.18), excluding two Patient Health Questionnaire-8 items (appetite and psychomotor changes). Among service members experiencing clinically significant PTSD change, concentration difficulties (73.3%), physical reactions to reminders (71.1%), and intrusions (70.8%) were PTSD symptoms most likely to persist. Poor sleep (56.2%), low energy (50.0%), and concentration difficulties (48.3%) were the most common for depression. Conclusions: To our knowledge, this study is the first to examine residual PTSD and depression symptoms following residential PTSD treatment for active duty service members. Given the low rates of clinically significant PTSD change and the high frequency of residual symptoms, strategies may be needed to improve residential PTSD treatment outcomes in the military. Klipstein, Lino von; Servaas, Michelle N.; Schoevers, Robert A.; van der Veen, Date C; Riese, Harriette	2023	Integrating personalized experience sampling in psychotherapy: A case illustration of the Therap-i module	Heliyon	9	3	e14507	<p>BACKGROUND: The experience sampling methodology (ESM) is increasingly being suggested as a clinical tool in mental health care, as it offers ecologically valid, microlevel information on psychopathological processes. Patients and clinicians have recommended that applications of ESM should be personalized and integrated into the existing clinical process, but there is still much uncertainty about how implementation may look like. OBJECTIVE: To provide an example of personalized ESM assessment and feedback being integrated into psychotherapy for depression, specifically looking at the collaborative use of ESM in case</p>

						<p>conceptualization. METHODS: George, a 27-year-old man diagnosed with depression, and his therapist participated in the Therap-i randomized controlled trial, which investigates the efficacy of a personalized ESM module added to psychotherapy. Together, they created a personalized ESM questionnaire, aiming to capture their hypotheses and questions regarding George's case conceptualization. George then filled out his ESM questionnaire five times per day, for 8 weeks. During this period, ESM data were discussed and interpreted by George, his therapist, and a researcher, in three feedback sessions. In these sessions, data were visualized in a flexible feedback interface that allowed for collaborative exploration of George's data. Both patient and therapist evaluated the module through questionnaires and George also participated in a semi-structured evaluation interview. RESULTS: George's ESM questionnaire included personalized items on the topics of self-esteem and open versus withdrawn behavior. He completed 241 (89.3%) assessments. Discussions during the feedback sessions focused on two core themes: First, George's low energy level, which was further explored with regard to his sleep, medication, and activity patterns. Second, his low sense of self-esteem, which led to an in-depth exploration of his thinking patterns and social interactions. The ESM module was seen as useful and insightful by both George and therapist. CONCLUSIONS: This case shows how ESM and ESM-based feedback can stimulate the collaborative exploration of the patient's complaints, and how it can provide useful insights for treatment. We discuss how our personalized ESM module relates to current clinical principles and practices, and make suggestions for further implementation.</p>

Kll-Senn, Cornelia	2016	"Feuer kann auch wrmen". Bindungsstrungen bei Pflegekindern	Existenzanalyse	33	1	95–98	Bindungsstrungen bei Pflegekindern werden betrachtet. Nach einer Verortung der Bindung in der Existenzanalyse und ihren Grundmotivationen wird die besondere Situation von Pflegekindern in ihrer Pflegefamilie beleuchtet. Dargestellt wird, wie sich frhe Traumatisierungen auf das Bindungsverhalten auswirken und wie daraus unter bestimmten Umstnden Bindungsstrungen entstehen knnen. Die verschiedenen Formen von Bindungsstrungen werden thematisiert und ihre Behandlung in der (existenzanalytischen) Psychotherapie von Kindern und Jugendlichen dargestellt. Beispiele aus der praktischen Erfahrung als Pflegemutter und Psychotherapeutin ergnzen die theoretischen berlegungen.
Knig, Julia; Unterhitzenberg er, Johanna; Calmer, Charlotta; Kohout, Pia; Karl, Regina; Rosner, Rita; Butollo, Willi	2020	What was helpful in today's session? Responses of clients in two different psychotherapie s for posttraumatic stress disorder	Psychotherapy: Theory, Research, Practice, Training	57	3	437–443	The aim of this study was to qualitatively analyze and compare the written responses clients in treatment for posttraumatic stress disorder (PTSD) gave when asked about helpful and negative aspects of the previous session. Data were collected during a randomized quantitative study comparing dialogical exposure therapy (DET, a gestalt-based integrative therapy, n = 58) and cognitive processing therapy (CPT, a cognitive-behavioral therapy, n = 52). We developed a coding manual using Mayring's (2015) qualitative content analysis approach and were able to code responses reliably. Five main categories emerged, unspecified and specific therapy elements, therapeutic relationship, client process, and general positive experience, with the first three containing subcategories. Each therapy had its own codes for specific therapy elements, while the other codes were identical for both treatments. The results for specific therapy elements were in accordance with the theories behind the two treatments. with CPT clients naming

							cognitive factors most frequently, whereas in DET, emotions were the most frequently mentioned. Results for therapeutic relationship were surprisingly similar given that DET therapists consider the therapeutic relationship to be an active ingredient, while CPT therapists consider it as the basis for the intervention rather than a working mechanism in itself.
Knmann, Sandra	2019	Naturtherapie. Mit Naturerfahrungen Beratung und Psychotherapie bereichern					Es wird aufgezeigt, wie die positive Wirkung des Naturerlebens die psychologische Begleitung von Einzelkunden unterstützen und bereichern kann. Entscheidend für den Therapieerfolg ist die Einbettung der Naturerfahrung in einen therapeutischen Bezugsrahmen, sowohl praktisch als auch theoretisch. Mit der "achtsamkeitsbasierten Naturtherapie" wird ein solcher Bezugsrahmen vorgestellt. Das Konzept verknüpft das psychotherapeutische Potenzial des Naturerlebens mit der Praxis der Achtsamkeit und wird getragen von einer humanistisch-personenzentrierten Haltung. Theoretisch fundiert und anhand zahlreicher Beispiele wird die konkrete Umsetzung im therapeutisch-beraterischen Alltag dargestellt. Es werden Anregungen für die häufigsten Störungsbilder (unter anderem Angststörungen, Depressionen, somatoforme Störungen, Traumafolgestörungen, Suchterkrankungen) sowie ausführliche Anleitungen zu naturtherapeutischen Interventionen gegeben. Darüber hinaus werden die Vielfalt und Entstehungsgeschichte naturtherapeutischer Konzepte nachgezeichnet sowie ein Überblick über den Stand der empirischen Forschung gegeben und grundlegende Fragen zur Beziehung von Mensch und Natur geklärt. Fallgeschichten, Insider-Tipps zur praktischen Anwendung sowie umfangreiches Zusatzmaterial ergänzen die Ausführungen. - Inhalt: (A) Theoretische Grundlagen.

							(1) Zehn Vorteile von Naturtherapie. (2) Was ist Natur? (3) Formen therapeutischen Arbeitens in der Natur. (4) Naturerfahrung und seelische Gesundheit - Stand der Forschung. (5) Grundzüge der achtsamkeitsbasierten Naturtherapie. - (B) Naturtherapie in der Praxis. (6) Naturtherapeutische Zugänge und Instrumente. (7) Fallgeschichten. (8) Naturtherapie bei speziellen Strukturbildern. (9) Praktische Umsetzung im therapeutischen Alltag.
Knmann, Sandra	2023	Alte Gespenster und neue Kraft . Eine personzentrierte Sitzung in der Natur	Gesprächspsychotherapie und Personzentrierte Beratung	54	4	10-11	Kein Abstract verfügbar.
Knmann, Sandra	2023	Den "Freiraum" nutzen: Wie Beratung und Psychotherapie in der Natur gelingen	Gesprächspsychotherapie und Personzentrierte Beratung	54	2	5-7	Die Covid-Pandemie hat nicht nur das öffentliche Leben stark beeinflusst, sondern auch die Arbeitsweise vieler Berufsgruppen verändert. Besonders Psychotherapeut*innen und psychologische Berater*innen waren gezwungen, ihre Arbeitsmethoden anzupassen, um ihre Klient*innen weiterhin hilfreich begleiten zu können. Ein Trend, der in diesem Zusammenhang in den letzten Jahren aufgekommen ist, ist die Verlegung von psychotherapeutischen Sitzungen in die Natur. Im Artikel werden die Chancen und Herausforderungen des Outdoor- Settings dargestellt und in den größeren Zusammenhang einer personzentrierten "Naturtherapie" eingeordnet.
Knopf, Alison	2020	Psychodynamic therapy for SUD: Counselor's view	Alcohol Drug Abuse Week (Alcoholism & Drug Abuse Weekly)	32	30	3-5	

Knowlton, Charlie N.; Nelson, Karl G.	2021	PTSD telehealth treatments for veterans: Comparing outcomes from in-person, clinic-to-clinic, and home-based telehealth therapies	Journal of Rural Mental Health	45	4	243–255	Recent advancements in video telehealth technology have increased access to specialty services for Veterans with posttraumatic stress disorder (PTSD) who could not otherwise attend therapy due to geographic and economic constraints. While previous literature has indicated comparable symptom reduction outcomes for in-person and telehealth care, recent findings from the 2019 J. D. Power U.S. Telehealth Satisfaction Study found Veteran apprehension about the perceived effectiveness of telehealth treatment. To address this, the present study compared the effects of prolonged exposure (PE) and cognitive processing therapy (CPT) on symptoms of PTSD and depression across in-person, clinic-to-clinic telehealth, or home-based telehealth delivery for a sample of Veterans. The study used a retrospective cohort design. Data were collected from 581 Veterans located within the Fargo Veterans Affairs (VA) Health Care System catchment area of the Veterans Integrated Service Network (VISN) 23, one of the most rural VISN areas in the nation, who initiated PTSD treatment between January 2017 and February 2020. Results showed significant reductions in symptoms of PTSD and depression for Veterans completing a full course of PE or CPT, regardless of treatment delivery modality. Overall findings suggested that PE and CPT, when delivered across any format, could produce satisfactory outcomes for Veterans living in rural areas. Koch, Theresa; Ehring, Thomas; Liedl, Alexandra	2017	Skills-Training der Affektregulation - ein kultursensibler Ansatz: STARK. Entwicklung und erste Erfahrungen mit afghanischen Geflchteten	Psychotherapeu tenjournal	16	4	316–323	Das Gruppentherapieprogramm "Skills-Training der Affektregulation - ein kultursensibler Ansatz: STARK" wird unter Bezugnahme auf eine Pilotstudie vorgestellt und diskutiert. Nach einem Verweis auf eine hohe Prvalenzrate von posttraumatischer Belastungsstrung (PBTS) und Depression bei Geflchteten wird die Entwicklung von STARK beschrieben. Fr die genannten Strungsbilder wird eine hohe transdiagnostische Bedeutung dysfunktionaler Emotionsregulation betont. Folglich fokussiert das aus vier Modulen bestehende, kognitiv-behaviorale Interventionsprogramm auf ein Training von Emotionsregulationsfhigkeiten. Es basiert auf bereits existierenden, evidenzbasierten Therapiemanualen, die kulturell adaptiert wurden. An der Pilotstudie nahmen sieben afghanische junge Mnner im Alter zwischen 15 und 18 Jahren teil. Vor und nach Abschluss des Gruppenprogramms, das aus 15 Sitzungen bestand, wurden Schwierigkeiten bei der Emotionsregulation, Angst- und Depressionswerte sowie Symptome einer PBTS erhoben. Im Pr-Post-Vergleich zeigte sich eine leichte Abnahme der Emotionsdysregulation, eine Verbesserung von Emotionsregulationsstrategien sowie eine hohe Therapiezufriedenheit. Die Symptomatik der posttraumatischen Belastungsstrung vernderte sich hingegen nicht. Mglliche Grnde hierfr werden diskutiert. Dennoch wird das STARK-Programm als vielversprechender Interventionsansatz eingestuft, dessen Wirksamkeit in einer geplanten randomisiert-kontrollierten Nachfolgestudie weiter geprft werden soll.
Koch-Kersten, Brigitte	2021	Personzentrierte Traumatherapie:					Traumatisierende Erfahrungen in der Kindheit knnen zu einer ablehnenden Haltung sich selbst gegenber fhren - zu Selbstverneinung. Sie entsteht durch die Identifikation

		Heilung durch Selbstbejahung				<p>mit erlebter Fremdverneinung (z.B. Abwertung, Demütigung oder Misshandlung). Selbstverneinung schränkt die Lebensqualität erheblich ein und ist die Ursache leidvoller Traumafolgesymptome. Die von der Autorin praktizierte personenzentrierte Traumatherapie besteht darin, diese Selbstverneinung aufzulösen, um Selbstbejahung, Selbstliebe und Selbstachtung wieder zu ermöglichen. Das Traumatherapiekonzept besteht aus einem Pendeln zwischen dem Zulassen und Bejahen von Gefühlen, auch den traumabedingten Leidensgefühlen, und dem Beachten und Bejahen von Abwehr und Widerstand.</p> <p>- Inhalt: (1) Überblick. <p>Koehler, Andreas; Strauss, Bernhard; Briken, Peer; Fisch, Margit; Soave, Armin; Riechardt, Silke; Nieder, Timo O.</p>	<p>2023</p>	<p>Exploring the Relationship between (De-)Centralized Health Care Delivery, Client-Centeredness, and Health Outcomes- Results of a Retrospective, Single-Center Study of Transgender People Undergoing Vaginoplasty</p>	<p>Healthcare (Basel, Switzerland)</p>	<p>11</p>	<p>12</p>		<p>Introduction: Transgender health care interventions (e.g., gender-affirming surgery) support transgender and gender-diverse people to transition to their gender and are delivered in both centralized (by one interdisciplinary institution) and decentralized settings (by different institutions spread over several locations). In this exploratory study, we investigated the relationship between centralized and decentralized delivery of transgender health care, client-centeredness, and psychosocial outcomes. Methods: A retrospective analysis of 45 clients undergoing vaginoplasty at one medical center was conducted. Mann-Whitney U tests assessed differences regarding five dimensions of client-centeredness and psychosocial outcomes between the health care delivery groups. To address shortcomings regarding the small sample size, we applied a rigorous statistical approach (e.g., Bonferroni correction) to ensure that we only identified predictors that were actually related to the outcomes. Results: All aspects of client-centered care were scored average or high. Decentralized delivery of care was more client-centered in terms of involvement in care/shared decision-making and empowerment. However, participants from decentralized health care delivery settings scored lower on psychosocial health ($p = 0.038-0.005$). Conclusions: The factor of (de-)centralized health care delivery appears to have a significant impact on the provision of transgender health care and should be investigated by future research.</p>
<p>Koenig, Harold G.</p>	<p>2023</p>	<p>Person-Centered Mindfulness: A Culturally and</p>	<p>Journal of religion and health</p>	<p>62</p>	<p>3</p>	<p>1884–1896</p>	<p>Mindfulness meditation is rapidly being integrated into many different forms of counseling and psychotherapy, and there is a growing evidence base for its effectiveness. It is important to understand the spiritual roots of</p>

		Spiritually Sensitive Approach to Clinical Practice					mindfulness, and to apply it in a patient-centered manner, sensitive to the patient's own faith tradition rather than taking a one-size-fits-all approach, assuming that mindfulness-based practice is a purely secular approach. The philosophical underpinning of mindfulness lies squarely in the Buddhist faith tradition. Indeed, mindfulness is the 7th step on the Eightfold Path, which is the heart of Buddhist teachings. Many practitioners, however, may not realize that there are Western meditative techniques that are very similar to mindfulness and that have deep roots within Christian, Jewish, and Muslim faith traditions. Patient-centered mindfulness involves the use of mindfulness and other meditation methods that are based on the patient's own faith tradition, rather than applying Eastern forms of mindfulness claiming these are a secular approach appropriate for everyone regardless of religious beliefs, even if those beliefs are not consistent with the Buddhist religious or philosophical approach. In this article, I briefly examine the evidence for the clinical effectiveness of mindfulness meditation, and then go into greater depth on Hindu, Buddhist, Christian, Jewish, and Muslim forms of mindfulness or similar meditative practices, providing resources that will better equip clinicians and researchers to provide patient-centered culturally-sensitive care.
Koffmann, Andrew	2019	Intersession improvement and outcome in psychotherapy	Clinical psychology & psychotherapy	26	1	146-155	OBJECTIVE Psychotherapy patients who experience large, stable symptomatic improvement between sessions are more likely than those without such sudden gains to benefit from treatment. However, there is limited empirical basis for the definition of sudden gains, and it is unclear how they may affect symptomatic change at other points in

							<p>treatment.</p> <p>METHOD</p> <p>In a psychotherapy training clinic, 149 adults completed a distress measure at each session. For each criterion in the definition of sudden gains, we evaluated the prediction of outcome, possible moderating variables, local score instability, and multisession change before and after score shifts.</p> <p>RESULTS</p> <p>Large intersession improvement did not lead to increased rate of change later in treatment, but it did predict outcome, regardless of whether nearby session scores were stable. Early improvement during the first five treatment sessions was an independent predictor of outcome. Large intersession improvement generally occurred in the context of local score instability.</p> <p>CONCLUSION</p> <p>Sudden gains appear to predict outcome because of improvement inherent in the gains themselves. Early overall improvement predicts outcome almost as effectively as do sudden gains. There may be advantages to redefining sudden gains as large intersession improvement, regardless of local score stability.</p>
Kohla, Eva	2019	Die Begegnung mit dem eisernen Heinrich. Ein Fallbericht	Existenzanalyse	36	1	122-128	<p>Die existenzanalytische Psychotherapie eines 52-jährigen Patienten mit den Diagnosen Alkoholkrankheit und schizoaffektive Störung wird beschrieben. Der Patient wird charakterisiert durch eine Beziehungsstörung zur Welt, zu anderen Menschen und zu sich selbst, ein depressives Mangelgefühl und Verbitterung. Die komplexen Wirkfaktoren des zugewandten Abholens und der beziehungsreichen therapeutischen Präsenz, die zu einem Einlassen auf die Therapie und Verbesserung des Zustandes des Patienten führten, werden dargestellt.</p>

Kohrt, Brandon A.; Griffith, James L.; Patel, Vikram	2018	Chronic pain and mental health: integrated solutions for global problems	Pain	159 Suppl 1	Su ppl 1	S85-S90	<p>Chronic pain is the leading cause of years lived with disability globally. Populations in low- and middle-income countries bear a disproportionate burden of chronic pain because of greater exposure to road injuries, interpersonal and political violence, unregulated manual labor and limited access to healthcare. Lessons from the field of global mental health can provide a foundation to begin tackling the global burden of pain. These lessons include the use of task-sharing of front-line psychosocial care to non-specialized health workers; a transdiagnostic approach; use of syndemic models incorporating social determinants and co-morbidities; incorporating cultural idioms of distress, the symbolic meaning of pain, and traditional healing practices; and a person-centered approach emphasizing the embedded nature of an individual in her/his family, context and culture. The implications of this evidence for chronic pain management are manifold, for example: using transdiagnostic psychosocial interventions delivered by non-specialist, non-physician health workers as the first step; personalized medicine approaches based on good practice principles of chronic disease management; and concurrently addressing the social determinants often associated with pain syndromes. Taken together, these principles should be used to design intervention platforms that can address the burden of chronic pain, while reducing risks of over-utilization of opioid medications, globally.</p>
Kolden, Gregory G.; Wang, Chia-Chiang; Austin, Sara B.; Chang,	2018	Congruence/genuineness: A meta-analysis	Psychotherapy	55	4	424-433	<p>Congruence or genuineness is a relationship element with an extensive and important history within psychotherapy. Congruence is an aspect of the therapy relationship with two facets, one intrapersonal and one interpersonal. Mindful genuineness, personal awareness,</p>

Yunling; Klein, Marjorie H.							<p>and authenticity characterize the intrapersonal element. The capacity to respectfully and transparently give voice to ones' experience to another person characterizes the interpersonal component. Although most fully developed in the person-centered tradition, congruence is highly valued in many theoretical orientations. In this article, we define and provide clinical examples of congruence. We also present an original meta-analysis of its relation with psychotherapy improvement. An analysis of 21 studies (k), representing 1,192 patients (N), resulted in a weighted aggregate effect size (r) of .23 (95% confidence interval = [.13, .32]) or an estimated d of .46. Moderators of the association between congruence and outcome are also investigated. In closing, we address patient contributions, limitations of the extant research, diversity considerations, and therapeutic practices that might promote congruence and improve psychotherapy outcomes.
